2. If the quadratic be affected, let it first be $x^2 + 2a\,x = b^2$; then form the right-angled triangle whose base AB (fig. 19) is a, and perpendicular BC is b; and with the centre A and radius AC, describe the semicircle DCE; so shall DB and BE be the two roots of the given quadratic equation $x^2 + 2\,a\,x = b^2$.

3. If the quadratic be $x^2 - 2\,a\,x = b^2$, then the construction will be the same as of the preceding one $x^2 + 2\,a\,x = b^2$.

4. But if the form be $2\,a\,x - x^2 = b^2$; form a right-angled triangle whose hypothenuse FG is a, (fig. 20.) and perpendicular GH is b; then with the radius FG and centre F describe a semicircle IGK; so shall IH and HK be the two roots of the equation $2\,a\,x - x^2 = b^2$ or $x^2 - 2\,a\,x = -b^2$. See Maclaurin's Algebra, part iii, cap. 2. and Simpson's Algebra, p. 267.

To construct cubic and biquadratic equations.—These are constructed by the intersections of two conic sections; for the equation will rise to four dimensions, by which are determined the ordinates from the four points in which these conic sections may cut one another; and the conic sections may be assumed in such a manner, as to make this equation coincide with any proposed biquadratic, so that the ordinates from these four intersections will be equal to the roots of the proposed biquadratic. When one of the intersections of the conic section falls upon the axis, then one of the ordinates vanishes; and the equation by which these ordinates are determined, will then be of three dimensions only, or a cubic; to which any proposed cubic equation may be accommodated. So that the three remaining ordinates will be the roots of that proposed cubic. The conic sections for this purpose should be such as are most easily described; the circle may be one, and the parabola is usually assumed for the other.

CONSUBSTANTIATION, a tenet of the lutheran church with regard to the manner of the change made in the bread and wine in the eucharist. The divines of that profession maintain, that after consecration, the body and blood of our Saviour are substantially present, together with the substance of the bread and wine; which is called consubstantiation or impanation.

CONSUL, is an officer established by virtue of a commission from the king and other princes, in all foreign countries of any considerable trade, to facilitate and despatch business, and protect the merchants of the nation. The consuls are to maintain a correspondence with the ministers of England residing in the courts whereon their consulate depends. They are to support the commerce and the interest of the nation; to dispose of the sums given and the presents made to the lords and principals of places, to obtain their protection, and prevent the insults of the natives on the merchants of the nation. By the treaty of Utrecht between Great Britain and Spain, the consul residing in the king of Spain's dominions shall take inventories of the estates of the English dying intestate in Spain; and these estates shall be intrusted to two or three merchants, for the security and benefit of the heirs and creditors.

CONSULTATION, in law, a writ by which a cause being removed from the spiritual court to the king's court, is returned thither again; and the reason is, that if the judges of the king's court, by comparing the libel with the suggestion of the party, find the suggestion false or not proved, and on that account the cause to be wrongfully called from the ecclesiastical court, then upon this consultation or deliberation they decree it to be returned. This writ is in the nature of a procedendo; yet properly a consultation ought not to be granted, only in cases where a person cannot recover at the common law. In causes of which the ecclesiastical and spiritual courts have jurisdiction, and they are not mixed with any temporal thing; if suggestion is made for a prohibition, a consultation shall be awarded. See PROHIBITION.

CONSUMPTION, in medicine, a word of very extensive signification, implies all disorders that bring any decay or waste upon the constitution. See MEDICINE.

CONTACT, is when one line, plane, or body, is made to touch another, and the parts that do thus touch are called the points or places of contact. The contact of two spherical bodies, and of a tangent with the circumference of a circle, is only in one point.

CONTAGION. See MEDICINE.

CONTENT, in geometry, the area or quantity of matter or space included in certain bounds.

CONTIGUOUS ANGLES, in geometry, are such as have one leg common to each angle; and are sometimes called adjoining angles, in contradistinction to those produced by continuing their legs through the point of contact, which are called opposite or vertical angles.

CONTINGENT, something casual or uncertain. Hence future contingent, in logic, denotes a conditional event which may or may not happen, according as circumstances fall out. The ancient Socinians maintained that God cannot forsee future contingents, because depending on the free motions of the will of man.

CONTINGENT is also a term of relation for the quota that falls to any person upon a division. Thus each prince in Germany, in time of war, is to furnish so many men, so much money and munition, for his contingent.

CONTINGENT USE, in law, is an use limited in a conveyance of lands which may or may not happen to vest, according to the contingency mentioned in the limitation of the use. And a contingent remainder is where no present interest passes; but the estate is limited to take effect, either to a dubious and uncertain person, or upon a dubious and uncertain event; so that the particular estate may chance to be determined, and the remainder never take effect.

CONTINUANCE, in law, is the continuing of a cause in court by an entry made for that purpose upon the records there.

CONTINUANCE *of a writ or action*, is its continuing in force from one term to another, where the sheriff has not returned a former writ issued out in the same action. With respect to continuances, the court of king's bench is not to enter them on the roll till after issue or demurrer, and then they enter the continuance of all on the back before judgment.

CONTINUANDO, a term used in a special declaration of trespass, where the plaintiff would recover damages for several trespasses in one and the same action. To avoid multiplicity of suits, a person may in one action of trespass recover damages for many trespasses committed, by laying the same to be done with a continuando.

CONTINUED PROPORTION, in arithmetic, is that where the consequent of the first ratio is the same with the antecedent of the second; as 4 : 8 : : 8 : 16, in contradistinction to the discrete proportion. See DISCRETE.

CONTINUO, in music, signifies the thorough bass, as basso continuo is the continual or thorough bass; which is sometimes marked in music books by the letters B. C.

CONTOBARDITES, in church history, a sect of heretics in the sixth century, who allowed of no bishops.

CONTOUR, the outline of a figure. It is sometimes used with great latitude, to express the general cast or lineaments of the visage. See PAINTING.

CONTOURNE', in heraldry, is used when a beast is represented standing or running with its face to the sinister side of the escutcheon; they being always supposed to look to the right, if not otherwise expressed.

CONTOURNIATED, a term among antiquaries applied to medals, the edges of which appear as if turned in a lathe. This sort of works seems to have had its origin in Greece, and to have been designed to perpetuate the memories of great men, particularly those who had borne away the prize at the solemn games. Such are those remaining of Homer, Solon, Euclid, Pythagoras, Socrates, and several athletæ.

CONTRA FORMAM COLLATIONIS, a writ that lies where a man had given lands to the warden and master of an hospital, to support certain poor men: if they alienated the land, then the donor or his heirs should bring this writ to recover them.

CONTRA FORMAM STATUTI, the usual conclusion of every indictment for an offence created by statute.

CONTRA FORMAM FEOFFAMENTI, is a writ which lies for the heir of a person enfeoffed of lands or tenements, who is distrained by the lord for more services than are contained in the charter of feoffment.

CONTRABAND, in commerce, a prohibited commodity or merchandise bought or sold, imported or exported, in prejudice to the laws and ordinances of a state, or the public prohibitions of the sovereign. Contraband goods are not only liable to confiscation themselves, but also subject all other merchandise found with them in the same box, bale, or parcel, together with the horses, waggons, &c. which conduct them. There are contrabands likewise, which, besides the forfeitures of the goods, are attended with several penalties and disabilities.

The principal goods prohibited to be imported into Great Britain, are *alamodes and lustrings, except in the port of London, and by licence; *ammunition, without licence from the king; *arms, without licence from the king; *bits for bridles; *popish books; brandy or rum, in casks less than 60 gallons, or in ships less than 15 tons burden; *buttons of all sorts; printed, painted, stained, or dyed callicoes; cards for wool, and playing cards; chocolate ready made, or cocoa paste; cinnamon without licence, except from India; *woollen cloths; *dice; leather gloves; East India, Persia, and China wrought silks, Bengals, stuffs mixed with silk, or herba, except into the port of London, and under special regulations; *fringes of silk or thread; gold or silver thread, lace, fringe, or other works made thereof; *malt from beyond sea; *salt in ships under twenty tons, or not in bulk; *silk embroidered, twined silk; *wrought silk mixed with gold, silver, or other materials; *tea, except by the India company; tobacco manufactured; *utensils of war, without licence from the king; *cut whale-bone.

Goods prohibited to be exported, are boxes, cases, or dial-plates, for clocks and watches, without the movement and makers' names; bullion, without proper certificates, &c.; frames for stockings; metal not of British ore, except copper-bars; wool; scouring and fuller's clay; sheep and sheep-skins with the wool; tallow; utensils used in the silk and woollen manufactory; white ashes, &c.

N.B. Such goods in the preceding list as have an asterisk perfixed before them, besides the forfeiture in common with the rest, are attended with several penalties.

CONTRAMANDATIO PLACITI, countermanding what was formerly ordered, and giving the defendant further time to answer

CONTRACT, a covenant or agreement between two or more persons, with a lawful consideration or cause.

Contracts are two-fold, either express or implied. Express contracts are, where the terms of the agreement are openly uttered, as to pay a stated price for certain goods. Implied, are such as reason and justice dictate, and which therefore the law presumes that every man undertakes to perform: thus if a man takes up wares from a tradesmen, without any agreement of price, the law concludes that he contracted to pay their real value. 2 Black. 443.

These are good contracts in law, because there is one thing in consideration for an another; but if a person promises to give or pay 20*s*, which afterwards, on being demanded, he refuses to pay, no action lies to recover it; because such a promise will not amount to a contract, it being no more than a bare promise, termed in law nudum pactum. Yet if any thing was given in consideration of such a promise, was it but to the value of a penny, it is deemed a good contract; and consequently will be binding. In contracts the time is to be regarded, in and from which they are made; and there is a difference where a day of payment is limited thereon, and where not: for when it is limited, the contract is good immediately, and an action lies on it without payment; but in the other case it is otherwise.

CONTRACT, *usurious*, is an agreement to pay more interest for money than the laws allow. See USURY.

It is a devastavit in executors, to pay a debt upon an usurious contract.

CONTRA-HARMONICAL *proportion*, in arithmetic, is that relation of three terms, wherein the difference of the first and second is to the difference of the second and third as the third is to the first: thus, 3, 5, and 6, are numbers contra-harmonically proportional, for 2 : 1 : : 6 : 3.

CONTRAST, the artificial opposition in works of painting and sculpture, of groups, attitudes, or colours; so as by their variety and striking difference, to enhance the value of each other. See PAINTING.

CONTRATE-WHEEL, in watch-work, that next to the crown, the teeth and hoop of which lie contrary to those of the other wheels, whence it takes its name. See CLOCK-WORK.

CONTRAVALLATION, in the military art, implies a line formed in the same manner as the line of circumvallation, to defend besiegers against the enterprises of the garrison; so that the army forming a siege lies between the lines of circumvallation and contravallation. The trench of this line is towards the town, at the foot of the parapet, and is never made but when the garrison is numerous enough to harass and interrupt the besiegers by sallies. This line is constructed in the rear of the camp, and by the same rule as the line of circumvallation, with this difference; that as it is only intended to resist a body of troops much inferior to a force which might attack the circumvallation, so its parapet is not made so thick, nor the ditch so wide and deep; six feet is sufficient for the first, with the ditch eight feet broad and five feet deep.

CONTRAYERVA, in the materia medica, the name by which the root of the dorstenia plant is known in the shops. See MATERIA MEDICA.

CONTRE, in heraldry, an appellation given to several bearings, on account of their cutting the shield contrary and opposite ways. Thus we meet with contre-bend, contre-chevron, contre-pale, &c. when there are two ordinaries of the same nature opposite to each other, so as colour may be opposed to metal, and metal to colour.

CONTRIBUTIONE *facienda*, in law, a writ that lies where the tenants in common are bound to do the same thing, and one or more of them refuse to contribute their part; as where they jointly hold a mill pro indiviso, and equally share the profits of it, if the mill fall to decay, and one or more of the persons refuse to contribute to its reparation, the rest shall have this writ to compel them.

CONTROL, COMPTROL, or CONTROLE, is properly a double register kept of acts, issues, &c. of the officers or commissioners in the revenue, army, &c. in order to perceive the true state thereof, and to certify the truth, and the due keeping of the acts subject to the enregisterment.

CONTROLLER, an officer appointed to control or oversee the accounts of other officers, and, on occasion, to certify whether or not things have been controlled or examined. In England there are several officers of this name; controller of the king's house, controller of the navy, controller of the customs, controller of the mint, &c.

CONTROLLER *of the hanaper*, an officer that attends the lord chancellor daily, in term and in seal-time, to take all things sealed in leather bags, from the clerks of the hanaper; and to mark the number and effect thereof, and enter them in a book, with all the duties belonging to the king and other officers for the same, and so charge the clerk of the hanaper with them.

CONTROLLER *of the pipe*, an officer of the exchequer, that makes out a summons twice every year, to levy the farms and debts of the pipe.

CONTROLLERS *of the pells*, two officers of the exchequer, who are the chamberlain's clerks, and keep a control of the pell of receipt, and goings out.

CONTUMACY, in law, a refusal to appear in court when legally summoned, or the disobedience to the rules and orders of a court having power to punish such offence. In a criminal sense, the contumacious is condemned, not because the crime is proved on him, but because he is absent. In England contumacy is to be prosecuted to outlawry.

CONTUSION, in medicine and surgery, any hurt of the body that is inflicted by a blunt instrument; and since, in this case, an indefinite number of small vessels and fibres are injured and broken, a contusion may properly be said to be a congeries of an indefinite number of small wounds. See SURGERY.

CONVALLARIA, or *lily of the valley*, a genus of the monogynia order, in the hexandria class of plants, and in the natural method ranking under sarmentaceæ, or 11th order. The corolla is sexfid; the berry spotted and trilocular. The species are 11, two of which are natives of Britain, viz. the maialis, or May lily; and the multiflora, or Solomon's seal. They are plants of considerable beauty, and may be easily propagated by their creeping roots.

CONVENTICLE, a diminutive of convent; denoting properly a cabal, or secret assembly, of a part of the monks of a convent, to make a brigue or party in the election of an abbot. From the ill use of these assemblies the word is come into disrepute; and now stands for any mischievous, seditious, or irregular assembly. The term conventicle is said, by some, to have been first applied in England to the schools of Wickliffe; and has been since used

to signify the religious assemblies of all in England who do not conform to the established doctrines and worship of the church.

By 22 Car. II. cap. 1, it is enacted, that if any persons of the age of 16 years, subjects of the kingdom, shall be present at any conventicle, where there are five or more assembled, they shall be fined five shillings for the first offence, and ten shillings for the second; and persons preaching incur a penalty of twenty pounds. Also suffering a meeting to be held in a house, &c. is liable to twenty pounds penalty. Justices of the peace have power to enter such houses, and seize persons assembled, &c. and if they neglect their duty they shall forfeit one hundred pounds. And if any constable, &c. know of such meetings, and do not inform a justice of peace, or chief magistrate, &c. he shall forfeit five pounds. But the 1st W. and M. cap. 18, ordains, that protestant dissenters shall be exempt from penalties: though if they meet in a house with the doors locked, barred, or bolted, such dissenters shall have no benefit from the act. Officers of the government, &c. present at any conventicle, at which there shall be ten persons, if the royal family be not prayed for in express words, shall forfeit forty pounds, and be disabled. Stat. 10 Anne, cap. 2.

CONVENTUAL, in general, denotes something belonging to a convent or monastery: thus monks who actually reside in a convent are called conventuals, in contradistinction to those who are only guests, or in possession of benefices depending on the house.

CONVERGING or *convergent lines*, in geometry, are such as continually approach nearer one another, or whose distance becomes still less and less. These are opposed to divergent lines, the distance of which becomes continually greater: those lines which converge one way diverge the other.

Converging hyperbola, is one whose concave legs bend in towards one another, and run both the same way.

Converging rays, in optics, those rays that, issuing from divers points of an object, incline towards another, till at last they meet and cross, and then become diverging rays. See Optics.

CONVERSE, in mathematics. One proposition is called the converse of another, when, after a conclusion is drawn from something supposed in the converse proposition, that conclusion is supposed; and then, that which in the other was supposed, is now drawn as a conclusion from it: thus, when two sides of a triangle are equal, the angles under these sides are equal; and, on the converse, if these angles are equal, the two sides are equal.

CONVERSION, in war, a military motion whereby the front of a battalion is turned where the flank was, in case the battalion is attacked in the flank.

Conversion *of equations*, in algebra, is when the quantity sought, or any part or degree of it, being in fractions, the whole is reduced to one common denomination, and then omitting the denominators, the equation is continued in the numerators only. Thus suppose $a - b = \frac{aa + cc}{d} + b + b$; multiply all by d, and it will stand thus, $da - db = aa + cc + dh + db$.

Conversion *of propositions*, in logic, the changing of the subject into the place of the predicate, and the predicate into the place of the subject; and yet always retaining the same quality of both propositions: as, Every right lined triangle has the sum of its angles equal to two right ones: Every right-lined figure that has the sum of its angles equal two right ones, is a triangle.

CONVEX, an appellation given to the exterior surface of gibbous or globular bodies; in opposition to the hollow inner surface of such bodies, which is called concave: thus we say, a convex lens, mirror, superficies, &c. See Optics.

CONVEYANCE, in law, a deed which passes land from one to another. The most common conveyances now in use are, deeds of gift, bargain and sale, lease and release, fines and recoveries, settlements to uses, &c. A conveyance cannot be fraudulent in part, and good as to the rest; for if it is fraudulent and void in part, it is void in all, and it cannot be divided. Fraudulent conveyances to deceive creditors, defraud purchasers, &c. are void, by stat. 50 Ed. III. c. 6. 13 Eliz. c. 5—27. Eliz. c. 4.

CONVICTION is either where a man is outlawed, or appears and confesses, or else is found guilty by the inquest. Cromp. Inst. 9.

Summary proceedings are directed by several acts of parliament for the conviction of offenders, and the inflicting certain penalties imposed by those acts. In these there is no intervention of a jury, but the party accused is acquitted or condemned by the suffrage of such person only as the statute has appointed for his judge.

The law implies that there must be a conviction before judgment, though not so mentioned in a statute; and where any statute makes a second offence felony, or subject to a heavier penalty than the first, it is always implied that such second offence ought to be committed after a conviction of the first. 1 How. 13—107. Judgment amounts to a conviction, though it does not follow that every one who is convict is adjudged. 1 Horn. 14. A conviction ought to be in the present tense, and not in the time past. Ld. Raym. 1376. Str. 608. A conviction ought to be on an information or claim precedent. Ld. Raym. 510.

When an act of parliament orders the conviction of offenders before justices of the peace, &c. it must be intended after summons to bring them in, that they may have an opportunity of making their defence; and if it be otherwise the conviction shall be quashed.

CONVICT-RECUSANT, one who has been legally presented, indicted, and convict, for refusing to come to church to hear the common prayer, according to the several statutes of 1 Eliz. 2. 23 Eliz. 1. and 3 Jac. I.

CONVIVIUM, *banquet*, in our old customs, a kind of tenure whereby the tenant was obliged to provide an entertainment for his lord once, or oftener, every year. It corresponded with the procuration of the clergy.

CONVOCATION, is the assembly of all the clergy to consult of ecclesiastical matters in time of parliament. There are two houses of convocation: the one called the higher convocation-house, where all the archbishops and bishops sit severally by themselves; the other the lower convocation-house, where all the rest of the clergy sit; that is, all the deans and archdeacons, one proctor for every chapter, and two proctors for all the clergy of each diocese: in all 166 persons.

The archbishop of Canterbury is the president of the convocation, and prorogues and dissolves it by mandate from the king. The convocation is not only to be assembled by the king's writ, but the canons made by them are to have the royal assent. They are to have the examining and censuring of heretical and schismatical books and persons, &c. but appeal lies to the king in chancery, or to his delegates. 4 Inst. 322. 2 Rol. Abr. 225. The clergy called to the convocation, and their servants, &c. have the same privileges as members of parliament. Stat. 8 H. VI. c. 1.

CONVOLVULUS, *bind-weed*, a genus of the pentandria class, and monogynia order, and in the natural method ranking under the 29th order, campanaceæ. The corolla is campanulated and plaited; there are two stigmata, the capsule is bilocular, and the cells are dispermous.

Of this genus there are 110 species, the most remarkable of which are the following:

1. The sepium, or large white bind-weed, is often a troublesome weed in gardens, when its roots are interwoven with those of trees and shrubs, or under hedges, as every small piece of root is apt to grow. It flourishes under moist hedges, and has white or purplish blossoms.

2. The scammonia, or Syrian bind-weed, grows naturally in Syria. The roots are thick, run deep into the ground, and are covered with a dark bark. The branches extend on every side to the distance of 10 or 12 feet: they are slender, and trail on the ground; and are furnished with narrow, arrow-pointed leaves. The flowers are of a pale yellow; and come out from the side of the branches, two sitting upon each long foot-stalk: these are succeeded by roundish seed-vessels, having three cells filled with seeds. From this species the scammony of the shops is produced.

3. The purpureus, or convolvulus major, an annual plant growing naturally in Asia and America, has been long cultivated in the British gardens. If these plants are properly supported, they will rise 10 or 12 feet high in warm summers. There are three or four lasting varieties: the most common has a purple flower; the others have a white, a red, or a whitish-blue flower, which last has white seeds. They flower in June, July, and August, and their seeds ripen in autumn.

4. The nil, or blue bind-weed, rises with a twining stalk 8 or 10 feet high; with heart-shaped leaves, divided into three lobes, which end in sharp points. These are woolly, and stand upon long footstalks. The flowers also come out on long footstalks, each sustaining two flowers of a very deep blue colour, whence their name of nil or indigo. This is one of the most beautiful plants of the genus: it flowers all the latter part of the summer, and in good seasons the seeds ripen very well in the open air.

5. The batatas, or Spanish potatoe, has esculent roots, which are annually imported from Spain and Portugal, where they are greatly cultivated for the table; but they are too tender to thrive in the open air in Britain. Their roots are like the common potatoe, but require much more room: for they send out many trailing stalks, which extend six or eight feet every way, and at their joints send out roots which in warm countries grow to be very large bulbs; so that from a single root planted 40 or 50 large potatoes are produced.

6. The canariensis, with soft woolly leaves, is a native of the Canaries, but has long been preserved in the British gardens. It has strong fibrous roots, whence arise several twining woody stalks, which, where they have support, will grow more than 20 feet high; garnished with oblong heart-shaped leaves, which are soft and hairy. The flowers are produced from the wings of the leaves, several standing upon one footstalk. They are for the most part of a pale blue; but there is a variety with white flowers. They appear in June, July, and August.

7. The tricolor, or convolvulus minor, is a native of Portugal, but has long been cultivated in the gardens of this country. It is an annual plant, which has several thick herbaceous stalks growing about two feet long; which do not twine like the other sorts, but decline towards the ground, upon which many of the lower branches lie prostrate: they have spear-shaped leaves, which sit close to the branches; the footstalks of the flowers come out just above the leaves of the same joint, and at the same side of the stalks. They are about two inches long, each sustaining one large open bell-shaped flower, which in some is of a fine blue colour with a white bottom; in others it is pure white, and some are beautifully variegated with both colours. The white flowers are succeeded by light seeds, and the blue by dark-coloured seeds: which difference is pretty constant.

8. The soldanella, or sea bind-weed, styled also brassica marina, grows naturally on the sea-beach in many parts of England, but cannot be long preserved in gardens. It has many small white stringy roots, which spread wide, and send out several weak trailing branches. These twine about the neighbouring plants like those of the common bind-weed, with kidney-shaped leaves like those of the lesser celandine. The flowers are produced on the side of the branches at each joint. They are of a redish-purple colour, and appear in July. They are succeeded by round capsules, having three cells, each containing one black seed.

9. The turpethum is a native of the island of Ceylon. This has fleshy thick roots which spread far in the ground; and abound with a milky juice that flows out when the roots are broken or wounded, and soon hardens into a resinous substance when exposed to the sun and air. From the root shoot forth many twining branches, which twist about each other, or the neighbouring plants, like the common bind-weed. They have heart-shaped leaves that are soft to the touch, like those of the marsh-mallow. The flowers are produced at the joints on the side of the stalks, several standing together on the same footstalk: they are white, and shaped like those of the common great bind-weed; and are succeeded by round capsules, having three cells containing two seeds each.

10. The jalappa, or jalap, used in medicine, is a native of Aleppo in Spanish America, situated between La Vera Cruz and Mexico. It has a large root of an oval form, full of milky juice; from which come out many herbaceous twining stalks, rising eight or ten feet high, with variable leaves; some of them being heart-shaped, others angular, and some oblong and pointed. They are smooth, and stand upon long footstalks: the flowers are shaped like those of the common greater bind-weed, each footstalk supporting only one flower. See Pl. XXXVI. Nat. Hist. fig. 142.

The second sort is propagated by seeds, which must be sown on a border of light earth. The plants must have some tall stakes placed near them for their branches to twine about, otherwise they will spread on the ground, and make a bad appearance. The third sort is annual, and must be propagated by seeds sown on a hotbed in spring; and towards the end of May they should be planted out in warm borders, and treated in the same manner with the former. The fourth species is sometimes propagated in this country. The roots must be placed on a hotbed in the spring: and if the plants are covered in the bad weather with glasses, they will produce flowers, and some small bulbs from the joints of the stalks; but if they are exposed to the open air they seldom grow to any size. The fifth is propagated by laying down the young shoots in the spring, which generally put out roots in three or four months: they may then be taken from the old plants, and each placed in a separate pot, which is to be set in the shade till they have taken new root; after which they may be placed with other hardy greenhouse plants till autumn, when they should be removed into the greenhouse, and afterwards treated in the same manner as myrtles and other greenhouse plants. The turbith and jalap are too tender to live in this country, unless they are constantly kept in a stove. The other species require no particular directions for their cultivation.

The root of the first sort proves a very acrid purgative to the human race, but is eaten by hogs in large quantities without any detriment. The inspissated juice of the second species is used in medicine as a strong purgative; as are also the roots of the jalappa and turpethum. The soldanella has likewise been used with the same intention. Half an ounce of the juice, or a drachm of the powder, is an acrid purge. The leaves applied externally are said to diminish dropsical swellings of the feet. See Materia Medica.

CONVOY, in marine affairs, one or more ships of war, employed to accompany and protect merchant ships, and prevent their being insulted by pirates, or the enemies of the state in time of war.

Convoy, in military affairs, a detachment of troops employed to guard any supply of men, money, ammunition, provisions, stores, &c. conveyed in time of war, by land or sea, to a town or army. A body of men that marches to secure any thing from falling into the enemy's hand, is also called a convoy. An officer having the command of a convoy must take all possible precautions for its security; and endeavour, before its march, to procure some good intelligence concerning the enemy's out-parties. And as the commanding officer of the place from which the convoy is to march, and those of such other places as he is to pass by, are the most proper persons to apply to for assistance; he must therefore take such measures as will enable him to keep up a constant intercourse with them. The conducting a convoy is one of the most important and most difficult of all military operations.

CONVULSION, *spasmus*. See Medicine.

CONYZA, *fleabane*, a genus of the polygamia superflua order, in the syngenesia class of plants, and in the natural method ranking under the 49th order, compositæ. The pappus is simple, the calyx imbricated and roundish, the corollulæ of the radius trifid. There are 41 species, none of which merit any particular description.

COOMB or *comb of corn*, a dry measure containing four bushels, or half a quarter.

COOPER, one who manufactures casks, tubs of all sizes, pails, and some other similar articles used in domestic concerns.

COPAIBA, or *balsam of copaiba*, a liquid resinous juice, flowing from incisions made in the trunk of the copaifera balsamum. Pure balsam of copaiba dissolves entirely in rectified spirit, especially if the menstruum is previously alkalized. Distilled with water it yields a large quantity of a limpid essential oil; and in a strong heat, without addition, a blue oil. See next article.

COPAIFERA, a genus of the monogynia order, in the decandria class of plants, and in the natural method ranking under those of which the order is doubtful. There is no calyx; there are four petals; the legumen ovate; one seed within an arillus, or coat, resembling a berry. We know of but one species, the officinalis, which yields the copaiba balsam mentioned in the preceeding article. This tree grows near a village called Ayapel, in the province of Antiochi, in the Spanish West Indies, about ten days journey from Carthagenia. There are great numbers of these trees in the woods about this village, which grow to the height of 30 or 60 feet. Some of these trees do not yield any of the balsam; those which do are distinguished by a ridge which runs along their trunks. These trees are wounded in the centre; and calabash shells, or some other vessels, are applied to the wounded part to receive the balsam, which will all flow out in a short time. One of these trees will yield five or six gallons of balsam: but though they will thrive well after being tapped, yet they never afford any more.

COPAL, a substance of great importance as a varnish, obtained from the rhus copalinum, a tree in North America. It is a beautiful transparent resinous-like substance. When heated it melts like other resins; but it differs from them in not being soluble in alcohol, nor in oil of turpentine without peculiar management. Neither does it dissolve in the fixed oils like other resins. The specific gravity of copal varies from 1.045 to 1.139. Mr. Hatchet found it soluble in alkalies and nitric acid with the usual phenomena; so that in this respect it agrees with the other resins. The solution of copal in alkalies he found indeed opalescent, but it is nevertheless permanent. It deserves attention, that he found resin when dissolved in nitric acid, and then thrown down by an alkali, to acquire a smell resembling that of copal.

When copal is dissolved in any volatile liquid, and spread thin upon wood, metal, paper, &c. so that the volatile menstruum may evaporate, the copal remains perfectly transparent, and forms one of the most beautiful and perfect varnishes that can well be conceived. The varnish thus formed is called copal varnish, from the chief ingredient in it. This varnish was first discovered in France, and was long known by the name of vernis martin. The method of preparing it is concealed; but different modes of dissolving copal in volatile menstrua have been from time to time made public. The following are the most remarkable of these:

When copal is kept melted till a sour-smelling aroma-

tic odour has ceased to proceed from it, and then mixed with an equal quantity of linseed oil which has been deprived of all colour by exposure to the sun, it unites with the oil, and forms a varnish, which must be dried in the sun.

When copal is treated with oil of turpentine in close vessels, the vapour, being prevented from escaping, exerts a greater pressure, and the heat rises above the boiling point. This additional heat is said to enable the oil to dissolve the copal. The solution, mixed with a little poppy oil, forms a varnish which is distinguished from the vernis martin merely in having a very slight tinge of brown.

The method of dissolving copal in oil of turpentine, published by Mr. Sheldrake, seems to depend upon the same principle with the last solution. On two ounces of copal, broken into small pieces, is poured a mixture of four ounces of ammonia, with a pint of oil of turpentine. The whole is kept boiling very gently, so that the bubbles may be counted as they rise. If the heat is allowed to diminish, or if it is raised too high, the process stops, and cannot be again resumed. The matrass in which the mixture is boiled, is stopped with a cork, secured in its place by a brass wire, and perforated by a pin. When the copal is nearly dissolved, the process is stopped, and the whole allowed to cool before uncorking the matrass. This varnish has a deep colour; but when spread thin and allowed to dry, it becomes colourless. Its defect is the difficulty with which it dries. This defect Mr. Sheldrake remedies by throwing the solution into its own weight of nut oil, rendered drying by white-lead, and agitating till the turpentine is separated.

To dissolve copal in alcohol Mr. Sheldrake dissolves half an ounce of camphor in a pint of that liquid, and pours the solution on four ounces of copal. The matrass is placed in a sand-bath, and the process is conducted exactly as that last described. The solution thus formed contains a great deal of copal, and forms a varnish which is perfectly colourless; but considerable heat is necessary to drive off the camphor. See VARNISH.

COPARCENARY. An estate held in coparcenary, is where lands of inheritance descend from the ancestor to two or more persons. It arises either by common law, or particular custom. By common law, as where a person seised in fee-simple, or fee-tail, dies, and his next heirs are two or more females, his daughters, sisters, aunts, cousins, or their representatives; in this case they shall all inherit: and these coheirs are then called coparceners; or, for brevity sake, parceners. Parceners by particular custom are, where lands descend, as in gavelkind, to all the males in equal degree, as sons, brothers, uncles, or other kindred; and in either of these cases, all the parceners put together make but one heir, and have but one estate among them. 2 Black. 137.

COPE, among ecclesiastical writers, an ornament usually worn by chantors and subchantors, when they officiated in the church solemnity. It is also worn by Romish bishops, and other ordinaries; and reaches from the shoulders to the feet.

COPE, among miners, a duty of 6*d.* for every load of ore.

COPERNICAN SYSTEM, that system of the world in which the sun is supposed at rest in the centre, and the planets, with the earth, to move in ellipses round him. See ASTRONOMY.

COPHTIC, or Coptic language, is that spoken by the Cophts; being the ancient language of the Egyptians, intermixed with the Greek, and the characters of it being those of the Greek. The ancient Coptic is now a dead language, to be met with no where but in books; and those only translations of the scriptures, and of ecclesiastical offices, or others that have a relation thereto; the language now used over all the country being the Arabic.

COPTIC MONKS, religious, among the Christians of Egypt, who have the highest veneration for a monastic life, considering it as the philosophy of the law of Jesus Christ, and the monks as terrestrial angels or celestial men. They are obliged to part with their possessions, to renounce marriage for ever, to live in deserts, to be clothed in wool, and to eat no meat.

COPIA LIBELLI DELIBERANDA, a writ that lies where a person cannot get the copy of a libel from a judge of the spiritual court.

COPING or *copping of a wall*, in architecture, the top or covert of a wall, made sloping to carry off the wet.

COPPER, a metal next to iron in specific gravity, but lighter than gold, silver, or lead.

If we except gold and silver, copper seems to have been more early known than any other metal. In the first ages of the world, before the method of working iron was discovered, copper was the principal ingredient in all domestic utensils and instruments of war. Even during the Trojan war, as we learn from Homer, the combatants had no other armour but what was made of bronze, which is a mixture of copper and tin. The word cuprum, or copper, is derived from the island of Cyprus; where it was first discovered, or at least wrought to any extent, by the Greeks.

This metal is of a fine read colour, and has a great deal of brilliancy. Its taste is styptic and nauseous; and the hands, when rubbed for some time on it, acquire a peculiar and disagreeable odour. Its specific gravity, when melted, is 8.667; but after being hammered it is 8.9. Its malleability is great: it may be hammered out into leaves so thin as to be blown about by the slightest breeze. Its ductility is also considerable. Its tenacity is such, that a copper wire 0.078 inch in diameter is capable of supporting 302.26 pounds avoirdupois without breaking. When heated to the temperature of 27° Wedgewood, or, according to the calculation of Mortimer, to 1450 degrees Fahrenheit, it melts, and if the heat is increased it evaporates in visible fumes. When allowed to cool slowly it assumes a crystalline form. The abbé Mongez, to whom we owe many valuable experiments on the crystallization of metals, obtained it in quadrangular pyramids, often inserted into one another.

Copper is not altered by water: it is incapable of decomposing it even at a red heat, unless air has free access to it at the same time; in that case the surface of the metal becomes oxydated. Every one must have remarked, that when water is kept in a copper vessel, a green crust of verdegris, as it is called, is formed on that part of the vessel which is in contact with the surface of the water. When copper is exposed to the air its surface is gradually tarnished; it becomes brown, and is at last covered with a dark-green crust. This crust consists of

oxyd of copper combined with carbonic acid gas. At the common temperature of the air, this oxydation of copper goes on but slowly; but when a plate of metal is heated red-hot, it is covered in a few minutes with a crust of oxyd, which separates spontaneously in small scales when the plate is allowed to cool. The copper plate contracts considerably in cooling, but the crust of oxyd contracts but very little; it is therefore broken to pieces, and thrown off, when the plate contracts under it. Any quantity of this oxyd may be obtained by heating a plate of copper, and plunging it alternately into cool water. The scales fall down to the bottom of the water.

In a violent heat, or when copper is exposed to a stream of oxygen and hydrogen gas, the metal takes fire and burns with great brilliancy, emitting a lively green light of such intensity, that the eye can scarcely bear the glare. The product is an oxyd of copper.

There are two oxyds of copper at present known; and it does not appear that the metal is capable of being exhibited in combination with more than two doses of oxygen. The protoxide is of a fine orange-colour; but the peroxide is black, though in combination it assumes various shades of blue, green, and brown.

1. The protoxide of copper was first observed by Proust; but we are indebted to M. Chenevix, who found it native in Cornwall, for the investigation of its properties. It may be prepared by mixing together 57.5 parts of black oxyd of copper, and 50 parts of copper reduced to a fine powder by precipitating it from muriatic acid by an iron plate. This mixture is to be triturated in a mortar, and put with muriatic acid into a well-stopped phial. Heat is disengaged, and almost all the copper is dissolved. When potash is dropt into this solution, the orange oxyd of copper is precipitated. But the easiest process is to dissolve any quantity of copper in muriatic acid by means of heat. The green liquid thus obtained is to be put into a phial, together with some pieces of rolled copper, and the whole is to be corked up closely. The green colour gradually disappears; the liquid becomes dark brown and opaque; and a number of dirty-white crystals, like grains of sand, are gradually deposited. When this liquid, or the crystals, are thrown into a solution of potash, the orange-coloured oxyd precipitates in abundance. This oxyd is composed of 88.5 parts of copper and 11.5 oxygen. It attracts oxygen with such avidity, that it can scarcely be dried without becoming bluish-green, at least on the surface: but when once dry it retains its colour pretty well.

2. The peroxide of copper is easily procured pure from the scales which are formed upon the surface of red-hot copper. These scales have a violet-red colour, owing to the presence of a little metallic copper upon their under surface; but when kept for some time red-hot in an open vessel, they become black, and are then pure peroxide of copper. The same oxyd may be obtained by dissolving copper in sulphuric or nitric acid, precipitating by means of potash, and then heating the precipitate sufficiently to drive off any water which it may retain. The peroxide of copper is composed of 80 parts of copper and 20 of oxygen. When mixed with somewhat less than its own weight of copper in powder, and heated to redness, the whole is converted into protoxide. The oxides of copper are easily reduced to the metallic state when heated with charcoal, oils, or other fatty bodies; and even with some of the metals, especially zinc.

3. When copper is dissolved in nitric acid, and a sufficient quantity of potash is added to the solution, a blue powder falls to the bottom, which was formerly considered as a peculiar oxyd of copper, and accordingly called blue oxyd of copper. But Mr. Proust has shown that it is nothing else than the black oxyd combined with water; and has therefore called it hydrat of copper. When distilled, 100 parts of it yield 25 parts of water, and there remain behind 75 parts of black oxyd. When this blue powder is exposed moist to the atmosphere, it gradually becomes green. This was formerly supposed to be owing to the absorption of oxygen; accordingly the green powder was called green oxyd of copper. But Mr. Proust has shown that this change is not owing to the absorption of oxygen, but to the combination of the black oxyd of copper with carbonic acid.

Copper has never been combined with carbon nor hydrogen; but it combines readily with sulphur and phosphorus, and forms with them compounds called sulphuret and phosphuret of copper.

When equal parts of sulphur and copper are stratified alternately in a crucible, they melt, and combine at a red heat. Sulphuret of copper thus obtained is a brittle mass, of a black or very deep blue grey colour much more fusible than copper; and composed, according to the experiments of Mr. Proust, of 78 parts of copper, and 22 of sulphur. The same compound may be formed by mixing copper filings and sulphur together, and making them into a paste with water, or even by merely mixing them together without any water, and allowing them to remain a sufficient time exposed to the air. Eight parts by weight of copper fillings, mixed with three parts of flowers of sulphur, are put into a glass receiver, and placed upon burning coals: the mixture first melts, then a kind of explosion takes place; it becomes red-hot, and, when taken from the fire, continues to glow for some time like a live coal. If we now examine it, we find it converted into sulphuret of copper. This experiment has excited great attention, and has been very often repeated; because it is the only instance known of apparant combustion without the presence of oxygen. Mr. Proust has shown that the sulphuret of copper is capable of combining with an additional dose of sulphur, and of forming a new compound which may be called supersulphuret of copper. It is brittle, has a yellow colour, and a metallic lustre; and is found native abundantly, being well known to mineralogists by the name of copper pyrites.

M. Pelletier formed phosphuret of copper by melting together 16 parts of copper, 16 parts of phosphoric glass, and one part of charcoal. Margraf was the first person who formed this phosphuret. His method was to distil phosphorus and oxyd of copper together. It is formed most easily by projecting phosphorus into red-hot copper. It is of a white colour; and, according to Pelletier, is composed of 20 parts of phosphorus and 80 of copper. This phosphuret is harder than iron: it is not ductile, and yet cannot easily be pulverized. Its specific gravity is 7.1220. It crystallizes in four-sided prisms. It is much more fusible than copper. When exposed to the air it loses its lustre, becomes black, falls to pieces, the

copper is oxydated, and the phosphorus converted into phosphoric acid. When heated sufficiently the phosphorus burns, and leaves the copper under the form of black scoriæ.

Copper is not capable of combining with azote. Muriatic acid gas readily converts it into oxyd, with which it enters into combination.

Copper is capable of combining with most of the metals; and some of its alloys are of very great utility.

The alloy of gold and copper is easily formed by melting the two metals together. This alloy is much used, because copper has the property of increasing the hardness of gold without injuring its colour. Muschenbroeck has ascertained that the hardness of this alloy is a maximum when it is composed of seven parts of gold and one of copper. The gold coin both in Britain and France is an alloy, containing eleven parts of gold and one of copper. Its specific gravity is considerably above the mean; consequently the density of the metals is increased by alloying them together. It ought to be 17.153, but it actually is 17.486; so that the density is increased one-forty-eighth part. This alloy being more fusible than gold, is employed as a solder to join pieces of that metal together.

Platinum may be alloyed with copper by fusion, but a strong heat is necessary. The alloy is ductile, hard, takes a fine polish, and is not liable to tarnish. This alloy has been employed with advantage for composing the mirrors of reflecting telescopes.

Silver is easily alloyed with copper by fusion. This alloy is harder and more sonorous than silver, and yet the density of the metals is diminished. Thus when 137 parts of silver and 7 of copper are alloyed together, the specific gravity ought to be 10.3016, but it actually is 10.1752; consequently the bulk of the two metals is increased by alloying them together about $\frac{1}{81}$ part. When the proportion of copper is small the colour of the silver is not altered. The silver coin of this country is composed of 1 part of copper and 11 of silver; that of France of 7 parts of copper and 137 of silver, or 1 part copper and 12.57 silver. The French silver coin therefore is purer than the American.

The amalgam of copper cannot be formed by simply mixing that metal with mercury, nor even by the application of heat; because the heat necessary to melt copper sublimes mercury. It may be obtained by triturating mercury with common salt and verdigris, or by keeping plates of copper in a solution of mercury and nitric acid. The amalgam is at first soft, and will take any impression; but it soon becoms hard when exposed to the air.

The affinities of copper and its oxyds are exhibited by Bergman in the following order:

Copper.	Oxyd of Copper.
Gold,	Oxalic acid,
Silver,	Tartaric,
Arsenic,	Muriatic,
Iron,	Sulphuric,
Manganese,	Saclactic,
Zinc,	Nitric,
Antimony,	Arsenic,
Platinum,	Phosphoric,
Tin,	Succinic acid,
Lead,	Fluoric,
Nickel,	Citric,
Bismuth,	Lactic,
Cobalt,	Acetic,
Mercury,	Boracic,
Sulphur,	Prussic,
Phosphorus.	Carbonic.

Copper is not unfrequently found native and malleable, sometimes in small and slender fibres, and sometimes in little globular and irregular masses. However, it is most frequently found in the state of ore, sometimes blended with the strata of stones, where it discovers itself in blue or green efflorescences. The green and blue ochres also are a sort of ores of copper, and the pyritæ and marcasites frequently contain large quantities of this metal. There is also a rich kind of copper ore of a reddish-grey colour; and another of a dusky-purple or blackish colour. But besides all these there are two other appearances of copper ore, known by the names of lapis lazuli, and the turcois or turquoise.

In Germany and Sweden there are very good mines of copper ore; and some in England, particularly in Cornwall, not inferior to the finest Swedish.

In order to discover whether the pyrites contains any copper, let it be roasted in an open fire, and a solution made by pouring upon it a quantity of warm water: into this solution let iron plates, perfectly clean and free from grease, be immersed; and if the pyrites contains any copper it will stick to these iron plates, in form of a fine yellow powder.

As to the method of obtaining copper from the ore, this last being previously washed and powdered, is smelted by means of a black flux; and the metal is found at the bottom of the vessel when cold, in the form of a solid and malleable mass; which may be farther refined by repeating the operation. See Mineralogy.

COPERAS, a name given to the martial or sulphate of green vitriol. See Iron.

COPULA, in logic, the verb that connects any two terms in an affirmative or negative: as, "Riches make a man happy;" where *make* is the copula: "No weakness is any virtue;" where *is* is the copula.

COPULATIVE PROPOSITIONS, in logic, those where the subject and predicate are so linked together by copulative conjunctions, that they may be all severally affirmed or denied one of another. Example, "Riches and honours are apt to elate the mind, and increase the number of our desires."

COPY, in a legal sense, is the transcript of an original writing; as the copy of a patent, of a charter, deed, &c. but a clause out of either cannot be given in evidence to prove the original, as it must be absolutely a true office-copy of the whole.

COPY-RIGHT. See Literary Property.

COR, the *heart*. See Anatomy.

Cor Caroli, in astronomy, an extra-constellated star in the northern hemisphere, situated between the coma Berenices and ursa major; so called by Dr. Halley in honor of king Charles.

COR HYDRÆ, a fixed star of the first magnitude, in the constellation of hydra.

COR LEONIS, or *regulus*, in astronomy, a fixed star of the first magnitude, in the constellation leo.

CORACIAS, the roller, in ornithology; a genus of birds of the order of picæ, the characters of which are: the bill is straight, bending towards the tip, with the edges cultrated: the nostrils are narrow and naked; the legs for the most part short: the toes placed three before and one behind, and divided to their origin. Sixteen species have been enumerated, though some of them are suspected to be only varieties. This genus is not confined to one spot of the globe, as one or other of the different species may be met with in all the four quarters of it. The following are the most remarkable:

1. The garrula, or garrulous roller, is about the size of a jay; the bill black, and at the base beset with bristles, which do not cover the nostrils: the head, neck, breast, and belly, are of a light-bluish green; back and scapulars, reddish brown; coverts on the ridge of the wing, rich blue, beneath them pale green; upper part and tips of the quills dusky; the lower parts of a fine deep blue; tail forked of a light blue; the legs are short and of a dirty yellow. Mr. Pennant observes that these birds are frequent in several parts of Europe, in most parts of which it is a bird of passage. Mention is made of them in Sweden and Denmark, on the one hand, and as far as Africa on the other: not that they are found in all the parts between, nor in the same plenty. Willughby tells us, that in Germany, Sicily, and Malta, they are so common as to be sold in the markets, and in poulterers' shops. Adanson says, "it comes to reside for some months of the summer in some parts of Europe, and goes back to spend the remainder of the year in Senegal," having shot one on board the ship, on its passage, in April. Frisch observes, that it makes its nests in woods, where there is birch; that it does not come to its colour till the second year; flies in troops in autumn; often seen in tilled grounds, with rooks and other birds, searching for worms, small seeds, and roots. Its flesh tastes like that of a turtle. It is said also sometimes to make its nest in holes in the ground, in one of which nests two eggs were found.

2. The cyanea, or blue-striped roller is in length eight inches; the bill three quarters of an inch long, bent at the tip, and of a black colour: the irides are red; the general colour of the plumage deep blue-black, dashed with streaks of greenish blue; the tail and legs are black; it inhabits New Caledonia.

3. The Sinensis, or Chinese roller, is of the size of a jay: the bill and irides are red; the head, hind part of the neck, back, rump, and upper tail-coverts, are green; the under parts of the body, from the chin to the vent, are yellowish white, tinged with green; but the thighs are grey; the wing-coverts are olive brown; quills the same, with a mixture of chesnut in some; the legs and claws are of a pale red, and longer than in other rollers. It inhabits China, and is called at Canton Santa-hoang. It is not very common.

CORAL *fishery*. Red coral is found in the Mediterranean, on the shores of Provence, from Cape de la Couronne to that of St. Tropez; about the isles of Majorca and Minorca; on the south of Sicily; on the coasts of Africa; and, lastly, in the Ethiopic ocean, about cape Negro. The divers say, that the little branches are found only in the caverns whose situation is parallel to the earth's surface and open to the south. The manner of fishing being nearly the same wherever coral is found, it will suffice to instance the method used at the bastion of France, under the direction of the company established at Marseilles for that fishery. Seven or eight men go in a boat commanded by the patron or proprietor, and when the net is thrown by the caster, the rest work the vessel, and help to draw the net in. The net is composed of two rafters of wood tied cross-wise, with leads fixed to them: to these they fasten a quantity of hemp twisted loosely round, and intermingled with some large netting. This instrument is let down where they think there is coral, and pulled up again when the coral is strongly entangled in the hemp and netting. For this purpose six boats are sometimes required; and if in hauling in, the rope happens to break, the fishermen run the hazard of being lost. Before the fishers go to sea, they agree for the price of the coral; which is sometimes more, sometimes less, a pound; and they engage, on pain of corporal punishment, that neither they nor their crew shall embezzle any, but deliver the whole to the proprietors. When the fishery is ended; which amounts one year with another to twenty-five quintals for each boat, it is divided into thirteen parts, of which the proprietor has four, the caster two, and the other six men one each: the thirteenth belongs to the company for payment of the boat furnished them. Red or white coral in fragments, for physic, pays on importation $7\frac{3}{4}d.$ the pound, and draws back on exportation $6\frac{4}{5}d.$ Whole coral unpolished, the pound, pays $3s.$ $10\frac{1}{2}d.$ and draws back $1s.$ $4\frac{4}{5}d.$ Whole coral polished, the pound, pays $5s.$ $1\frac{1}{2}d.$ and draws back $4s.$ $7\frac{4}{5}d.$

CORALLINA, or *coral*, in zoology, a genus belonging to the order of vermes zoophyta. The trunk is radicated, jointed, and calcareous. The species are distinguished by the form of their branches, and are found in the ocean adhering to stones, bones, shells, &c. The corals were formerly believed to be vegetable substances hardened by the air; but are now known to be composed of a congeries of animals, which are even endued with the faculty of moving spontaneously. The islands in the South-sea are mostly coral rocks covered over with earth. The little creatures, which have scarcely sensation enough to distinguish them from plants, build up a rocky structure from the bottom of that sea, too deep to be measured by human art, till it reaches the surface. Some of the coralline islands appear to be of a much older date than others; particularly the Friendly Islands: and it is probable that, as these submarine works are continually going on, new islands may by that means frequently be produced. M. de Peyssonel of Marseilles, in consequence of a series of experiments and observations from about the year 1720 to 1750, seems to have been the first who threw a proper light upon the nature and productions of coral and similar marine substances. Those bodies which the count de Marsigli imagined to be flowers, this ingenious naturalist discovered to be insects inhabiting the coral; for upon taking branches of it out of the water, the flowers, which proceeded from a number of white points answering to the holes that pierced the bark, and the radiaton of which resembled the flower of the olive-tree, entered into the bark, and disappeared: but upon being again restored to the

water, they were some hours after perceptible. These flowers spread on white paper lost their transparency, and became red as they dried. The holes in the bark correspond to small cavities upon the substance of the coral; and when the bark is removed there may be seen an infinite quantity of little tubes connecting the bark with the inner substance, besides a great number of small glands adhering to them; and from these tubes and glands the milky juice of coral issues forth: the holes in the bark are the openings through which the insects that form these substances for their habitation come forth: and those cavities which are partly in the bark, and partly in the substance, are the cells which they inhabit. The organs of the animal are contained in the tubes, and the glandules are the extremities of its feet; and the milky liquor is the blood and juice of the animal, which are more or less abundant in proportion to its health and vigour. When the insects are dead, they corrupt, and communicate to the water the smell of putrid fish. The juice or liquor runs along the furrows perceived upon the proper substance or body of coral, and stopping by little and little becomes fixed, and hard, and is changed into stone; and being stopped in the bark, causes the coral to increase proportionably and in every direction. In forming coral, and other marine productions of this class, the animal labours like those of the testaceous kind, each according to his species; and their productions vary according to their several forms, magnitudes, and colours.

The coral insect, or polype, expands itself in water, and contracts itself in air, or when it is touched with the hand in water, or acid liquors are poured upon it: and he actually saw these insects move their claws or legs, and expand themselves, when the sea-water containing coral was placed near the fire, and keep them in their expanded state when separated from the coral in boiling water. Broken branches of coral have been observed to fasten themselves to other branches, and have continued to grow; and this is the case when they are connected with detached pieces of rock and other substances, from which no nourishment could be derived. The coral insects in their cells, not having been injured, continue their operations; and as they draw no nourishment from the stone of the coral, they are able to increase in a detached and separate state. Coral was found to be equally red in the sea as out of it; and it was more shining when just taken out of the water than even when it is polished; and the bark by being dried becomes somewhat pale. It grows in different directions, sometimes perpendicularly downwards, sometimes horizontally, and sometimes upwards; and in the caverns of the sea, open to every exposure.

M. Donati of Turin has also adopted the same hypothesis, viz. that coral is a mass of animals of the polype kind; and instead of representing the coral beds and cells which contain them as the work of polypes, he thinks it more just to say, that coral and other coralline bodies have the same relation to the polypus united to them, that there is between the shell of a snail and the snail itself, or the bones of an animal and the animal itself.

There are properly but three kinds of coral; red, white, and black: the black is the rarest and most esteemed; but the red was formerly in great repute as a medicine. When coral is newly taken up out of the sea, the small protuberances on its surface are soft, and yield, on being pressed, a milky juice which effervesces with acids. The cortical part with which the coral is all over covered is not near so compact as the internal, and may be easily taken off whilst fresh; and from this part it is usually freed before it comes to the market. The greatest coral trade is in Genoa and Leghorn. See Plate XXXVI. Nat. Hist. fig. 143.

CORALLINES, in natural history, were formerly reckoned a genus of plants, and Mr. Tournefort enumerates 36 species of them; but in the Linnæan system they belong to the class zoophytes, and are defined by modern naturalists to be submarine plant-like bodies, that consist of many slender finely divided and jointed branches, resembling some species of moss; or animals growing in the form of plants, having their stems fixed to other bodies; these stems are composed of capillary tubes, whose extremities pass through a calcareous crust, and open into pores on the surface. The branches are often jointed, and always subdivided into smaller branches which are either loose and unconnected, or joined as if they were glued together. They are distinguished from plants by their texture and hardness: they also yield in distillation a considerable quantity of volatile salt; and their smell, in burning, resembles that of burnt horns and other animal substances. Many of the corallines seem to consist of a single tube, containing a single parent animal. Every branch emitted contains an offspring of this parent dependant upon it, and yet capable of producing its like in the emission of a new branch. Others consist of many such tubes united, rising together, and encircling the deserted tubes of their progenitors, whose exuviæ become the substratum of a rising generation. Mr. Ellis distributes corallines into the vesiculated, tubular, celliferous, and articulated kinds.

Vesiculated corallines are distinguished by their horny hollow ramifications: most of them are furnished with little denticles on their branches, like leaves on mosses; and at certain seasons of the year they are furnished with small bodies like bladders, proceeding from their stems and branches, and differing in form according to the different species. Their colour, when dry, is of a yellowish or pale brown, and their nature is elastic. They are found adhering to rocks, shells, and fucuses, by small root-like tubes: they recover their form in water, after having been dried; and when put into vinegar, they cause no effervescence. See Plate XXXV. fig. 1, where *a* represents the sea-tamarisk in its natural size, and A the denticles considerably magnified. Fig. 2. *b*, B, are the sea-cypress: fig. 3. *cd*, CD, the small climbing coralline with well-shaped cups.

Tubular corallines are composed of a number of simple tubes, growing up nearly together; or of such branched ones as have neither denticles nor vesicles. These are horny and elastic like the former, and recover their original form in water. Some of them appear wrinkled like the windpipe, and others like the intestines of small animals. See E, fig. 4.

Celliferous corallines are those which appear, when magnified, to be fine thin cells, the habitations of small animals connected together, and disposed in a variety of elegant forms like branches. These effervesce with acids. See fig. 5. F, *f*, with a part (G H) magnified.

Articulated corallines consist of short pieces of a stony or cretaceous brittle matter, whose surface is covered with pores or cells which are joined by a tough, mem-

branous, flexible substance, composed of many small tubes of the like nature compacted together. The stony part is soluble in vinegar, and the other part remains entire. Fig. 6 is the coralline of the shops. It is fixed to rocks and shells by stony joints, which, as they rise, are united to others by extremely fine and slender tubes: these may be discovered by a good eye, or a common magnifier. As the stems extend themselves, they become penetrated by side-branches which come out opposite to each other, and are joined in the same manner; the joints of this species are like the upper part of an inverted cone, but a little compressed: the whole surface is covered over with very minute circular-shaped cells like pores. If a branch of this coralline is put into vinegar, these cells are dissolved with the whole cretaceous substance; instead of which there appear rows of minute ramifications, which seem to have communicated with each of these cells. Upon some specimens of this coralline, we may observe small figures like seed-vessels, with which the branches frequently terminate: they are also found on the sides, as may be seen at A, where they are magnified. When a branch is rendered soft by being steeped in vinegar, there may be squeezed out from the little knobs at the ends and sides, small twisted figures. We frequently find this coralline of different colours, as red, green, ash, and white; but all of it, being exposed to the sun and air on the shore, becomes white. Besides the above, Mr. Ellis enumerates other genera of marine productions; as the keratophyta eschara fig. 7, sponges, and alyconium; all which are the nests or matrices of sea-animals. This class of marine bodies is formed like fungi of various figures, and with different sorts of covering; some having a gritty, and some a callous skin, with spongy substance in the inside: other species are of a fleshy substance.

C and C 1 are views of one of the warts magnified: C 2 is the appearance of the polype, when the cretaceous matter was dissolved: C 3 represents the particles that compose the incrustation, magnified; D fig. 8, is a sea-willow, or keratophyton dichotomum.

CORANICH, among the Scotch and Irish, the custom of singing at funerals, anciently prevalent in those countries, and still practised in several parts. Of this custom Mr. Pennant gives an account, having assisted at one in the south of Ireland, where it was performed in the fullness of horror. "The cries (says he) are called by the Irish ugohene and hullulu; two words very expressive of the sound uttered on these occasions; and being the Celtic stock, etymologists would swear to be the origin of the ολολυγαν of the Greeks, and ululatus of the Latins. Virgil is very fond of using the last whenever any of his females are distressed; as are others of the Roman poets, and generally on occasions similar to this. It was my fortune to arrive at a certain town in Kerry at the time that a person of some distinction departed this life; my curiosity led me to the house, where the funeral seemed conducted in the purest classical form. The conclamatio was set up by the friends in the same manner as Virgil describes that consequential of Dido's death. Immediately after this followed another ceremony, fully described by Camden in his account of the manners of the ancient Irish; the earnest expostulations and reproaches given to the deceased for quitting this world, where she enjoyed so many blessings, so good a husband, and such fine children. But when the time approached for carrying out the corpse, the cry was redoubled. 'Tremulis ululatibus æthera complent' a numerous band of females waiting in the outer court to attend the hearse, and to pay in chorus the last tribute of their voices. The habits of this sorrowing train, and the neglect of their persons, were admirably suited to the occasion; their robes were black and flowing, resembling the ancient pillia; their feet naked, and their hair long and dishevelled. The corpse was carried slowly along the verge of a most beautiful lake, the ululatus was continued, and the whole procession ended among the venerable ruins of an old abbey."

The same custom prevailed among the Hebrews, and is beautifully described in bishop Lowth's justly celebrated Lectures on the Sacred Poetry of the Hebrews.

CORBAN, in Jewish antiquity, where those offerings which had life, in opposition to the minchah, or those which had not. It is derived from the word karab, which signifies "to approach;" because the victims were brought to the door of the tabernacle. The corbans were always looked upon as the most sacred offerings. The Jews are reproached with defeating, by means of the corban, the precept of the fifth commandment, which enjoins the respect due to parents: for when a child had no mind to relieve the wants of his father or mother, he would say to them, "It is a gift (corban) by whatsoever thou mightest be profited by me;" i. e. "I have devoted that to God which you ask of me, and it is no longer mine to give."

Corban is also a ceremony which the Mahometans perform at the foot of mount Ararat in Arabia, near Mecca. It consists in killing a great number of sheep, and distributing them among the poor.

CORBEILS, in fortification, little baskets about a foot and a half high, eight inches wide at the bottom, and twelve at the top; which being filled with earth, are frequently set one against another upon the parapet or elsewhere, leaving certain port-holes, whence to fire upon the enemy under covert, without being seen by them.

CORBEL, in architecture, the representation of a basket, sometimes seen on the heads of caryatides. The word is also used, in building, for a short piece of timber placed in a wall, with its end sticking out six or eight inches, as occasion serves, in manner of a shouldering-piece.

CORCELET, in natural history, that part of the fly-class which is analogous in its situation to the breast in other animals. Many have called it the breast in these also, but improperly; because the breast of other animals is the seat of the lungs and trachea, but these organs are in the fly-class distributed through the whole body. The wings are affixed to this part in the fly-class; and there are some distinctions of great consequence in regard to the arrangement and distribution of these animals into genera. Some flies have a double corcelet, or one divided into two parts; and this is the case of the fly produced from the formica, leo, which therefore does not carry its only distinction in the figure of its antennæ. One pair of the legs of this fly are attached to the first or anterior corcelet, which is also capable of moving on the other.

The corcelets of some flies are also much more elevated than those of others; and in some this elevation is

carried so far, that the head is forced by it to be bent downward, and the creature is nearly made hump-backed by it. The gnat kind, and the tipulæ, furnish instances of this elevated and hump-backed form. A series of flies of two wings are known by a very particular armament which they carry on the corcelet, usually called their breast. This consists of two long slender sharp-pointed prickles, which are immoveable in their insertions, and seem meant as offensive or defensive weapons; but in what manner they are used is not easily to be determined. All these flies are produced from long water-worms with open and funnel-fashioned tails, or furnished with their aperture for respiration at the hinder extremity.

CORCHORUS, a genus of the monogynia order, in the polyandria class of plants, and in the natural method ranking under the 37th order, columniferæ. The corolla is pentapetalous, the calyx pentaphyllous and deciduous, and the capsule many-valved and many-celled. There are 16 species; of which the most remarkable is the olitorius, an annual, and a native of Asia, Africa, and America. It rises with a round, striated, upright, branched stalk, to near two feet, with leaves differing in shape; some being oval, some cut off straight at their base, and others almost heart-shaped. The flowers come out at the sides of the branches opposite to the leaves. They stand singly on very short peduncles; are composed of five small yellow petals, and a great number of stamina surrounding an oblong germen, which becomes a long, rough, sharp-pointed capsule, opening in four parts, each filled with greenish angular seeds. This plant is sold by the Jews about Aleppo, and is therefore called Jew's mallow. The leaves are a favourite salad among that people; and they boil and eat them with their meat.

CORCULUM. See BOTANY, and PLANTS.

CORD OF WOOD, a certain quantity of wood for burning, so called because formerly measured with a cord. The dimensions of a statute cord of wood are eight feet long, four feet high, and four feet broad.

CORDAGE, a term used, in general, for all sorts of cord, whether small, middling, or great, made use of in the rigging of ships. Cordage cable-laid, as the seamen term it, is made with nine strands, *i. e.* the first three strands are laid slack, and then three of them being closed together, make a cable. See CABLE.

The same for tacks, but they are laid tapering.

Cordage hawser-laid, is made only with three strands. Cordage-stays are cable-laid, but made with four strands, as cables are with three; with the addition of a heart, which goes through the centre of them.

White cordage is that which has not yet been tarred. Cordage tarred in spinning is that which is made of rope-yarn ready tarred.

Cordage tarred in the stove is that which has passed through hot tar, in coming out of the stove. Every quintal of cordage may take about twenty pounds of tar. Cordage remade is that which is made of ropes used before. Cordage, when very old, is used for oakum to caulk the seams of ships.

When a rope is said to be six inches it is understood of its circumference. A rope of sixty threads is one composed of so many rope-yarns.

CORDED, in heraldry. A cross-corded some authors take for a cross-wound or wrenched about with cords.

CORDELIER, in church history, a Franciscan, or religious of the order of St. Francis. The cordeliers are enjoined to live in common: those who are admitted into the order, are first to sell all they have and give it to the poor. The priests are to fast from the feast of All Saints till the Nativity.

CORDIA, a genus of the monogynia order, in the pentandria class of plants, and in the natural method ranking under the 41st order, asperifoliæ. The corolla is funnel-shaped; the style dichotomous or divided into two threads, and each of these divided into other two. There are five species, of which the principal are the myxa and sebestena.

1. The myxa, or Assyrian plum, grows wild in Assyria or Egypt, and also on the coast of Malabar. It rises to the height of a middling plum-tree; and its branches are furnished with oval woolly leaves, standing without order. The flowers are produced in bunches; are white, and consist of one tubular petal, and a like calyx, nearly of an equal length, and both are cut into five parts to their brims. In their centre are five very small stamina, and one slender style crowned with an obtuse stigma. The germen is roundish, and swells to a plum of the same form, and about the size of a damson, of a dark brown colour, a sweet taste, and very glutinous. In some parts of Turkey they cultivate this tree in great abundance, not only for the sake of the fruit to eat, but to make birdlime of, which is a great article of trade in a town called Seid.

2. The sebestena, or rough-leaved cordia, grows naturally in both the Indies, and sends forth several shrubby stalks eight or ten feet high. The young leaves are serrated, but the full-grown ones are not. They are of an oblong oval form, rough, of a deep green, and stand alternately on footstalks. The flowers terminate the branches in large clusters of the shape and colour of the marvel of Peru, and wear a most beautiful appearance. Each has five stamina and one bifid style. The plums are much of the shape of those of the myxa, and are eaten in the same manner. The fruit of this tree is less valuable than the wood, a small piece of which thrown upon a clear fire will perfume a room with a most agreeable odour.

CORDIAL, in medicine, whatever raises the spirits, and gives them a sudden strength and cheerfulness. See MEDICINE.

CORDON, in fortification, a row of stones, made round on the outside, and set between the wall of the fortress which lies aslope, and the parapet which stands perpendicular, after such a manner, that this difference may not be offensive to the eye; whence the cordons serve only as an ornament, ranging round about the place, being only used in fortifications of stone-work: for in those made with earth the void spaces is filled up with pointed stakes.

CORDWAINERS, the term whereby the statutes denominate shoemakers. The word is formed from the French cordonnier, which Menage derives from cordouan, a kind of leather brought from Cordova, of which they formerly made the upper leathers of their shoes. Others derive it from cords, because anciently shoes

were made of cords; as they still are in some parts of Spain, under the name of alpargates. But the former etymology is better warranted: for, in effect, the French workmen who prepare the cordovas are still called cordouanniers. In Paris, before the revolution, they had two pious societies under the title of freres cordonniers. The produce of their shoes went into a common stock, to furnish necessaries for their support; and the rest was distributed among the poor.

COREOPSIS, tickseeded sunflower: a genus of the polygamia frustranea order, in the syngenesia class of plants, and in the natural method ranking under the 49th order, compositæ. The receptacle is paleaceous; the pappus two-horned; the calyx erect and polyphyllous, surrounded with patent radiated leaflets at the base. There are 20 species, most of them herbaceous perennials. They rise from 3 to 8 feet; terminated by clusters of compound radiated flowers of a yellow colour. They have all perennial fibrous roots, and annual stalks, which rise in the spring, flower from July to October, and decay to the root in November. The flowers are all shaped like sun-flowers, but smaller, and are very ornamental. They are easily propagated by slipping or dividing the roots in autumn.

CORIANDRUM, *coriander*, a genus of the digynia order, in the pentandria class of plants, and in the natural method ranking under the 45th order, umbellatæ. The corolla is radiated; the petals inflexed-emarginated; the involucrum universal and monophyllous; the partial involucra halved; the fruit spherical. There are only two species, both of them herbaceous annuals, the leaves of which are useful for the kitchen, and the seeds for medicine. Both species have divided small leaves, somewhat resembling parsley: but there is only one species generally cultivated, namely, the sativum. This has a small fibrous white root, crowned by many-parted leaves, having broadish segments; and in the centre an upright, round, branchy stalk, two feet high, having all the branches terminated by umbels of flowers, which are succeeded by globular fruit. It is propagated by seed, which, when a good crop is wanted, ought to be sown in March, either in drills a foot asunder, or by broadcast, and then raked in. When the plants are an inch or two high, they should be hoed to six or eight inches distance. The seeds, when fresh, have a strong disagreeable smell, which improves by drying, and becomes sufficiently grateful: they are recommended as carminative and stomachic.

CORIARA, the *tanner's* or *myrtle-leaved sumach*, a genus of the decandria order; in the dioecia class of plants, and in the natural method ranking under the 54th order, miscellaneæ. The male calyx is pentaphyllous; the corolla pentapetalous, very like the calyx, and united with it; the antheræ bipartite. The female calyx is pentaphyllous; the corolla like that of the male; the styles five, seeds five, covered with a like number of succulent petals, forming altogether the resemblance of a berry. There are three species, the myrtifolia, rusufolia, and the sarmentosa. The first two are natives of the south of France, but the last is most commonly cultivated in this country. It is a pretty ornamental plant, with a shrubby pithy brown stem, closely branching from the bottom; and forms a bushy head three or four feet over, with oblong, pointed, bright-green leaves, having small spikes of whitish flowers at the ends of the branches. It is easily propagated by suckers from the root, in which it abounds plentifully, and may be taken off with fibres every autumn or winter. It is much used in France for tanning leather, whence its name tanner's sumach.

CORINTHIAN ORDER. See ARCHITECTURE.

CORIS, a genus of the monogynia order, in the pentandria class of plants, and in the natural method ranking with those of which the order is doubtful. The corolla is monopetalous and irregular; the calyx prickly; the capsule quinquevalved, superior. There is only one species, viz. the monspeliensis, or blue maritime coris. There are two varieties of this plant, one with a red, and the other with a white flower; but these are only accidental, and arise from the same seeds. They grow wild about Montpelier, and in most places in the south of France: they seldom grow above six inches high, and spread near the surface of the ground like heath; and in June, when they are full of flowers, make a very pretty appearance. They may be propagated by sowing their seeds in a bed of fresh earth, and afterwards removing the young plants, some in pots, and others into a warm border. They generally bear out winter colds well enough, but severe frosts will sometimes destroy them; for which reason it is proper to keep some of them in pots, which should be put under a hotbed frame in winter.

CORISPERMUM, *tickseed*, a genus of the digynia order, in the monandria class of plants, and in the natural method ranking under the 12th order, holoraceæ. There is no calyx; two petals, and one oval naked seed. There are two species; but neither of them are remarkable for their beauty, or any other quality.

CORK. See QUERCUS.

CORK-FOSSIL, a name given to a kind of stone. It is a species of amianthus, consisting of flexible fibres loosely interwoven, and somewhat resembling vegetable cork. It is the lightest of all stones; by fire it is fusible, and forms a black glass.

CORK-JACKET, a kind of waistcoat, composed of four pieces of cork, two for the breasts, and two for the back; each pretty near, in length and breadth, to the quarters of a waistcoat without flaps; the whole is covered with coarse canvas, with two holes to put the arms through. There is a space left between the two back-pieces, and the same betwixt each back and breast-piece, that they may set the easier to the body. Thus the waistcoat is only open before, and may be fastened on the wearer with strings; or, if it should be thought more secure, with buckles and leather straps. This waistcoat is the invention of Mr. Dubourg: but it has been improved by Dr. Wilkinson, of Woodford, who rendered it much more accommodating to the motions of the body in swimming, by cutting the cork into small pieces and quilting them between two waistcoats of canvas. Even the most timorous, with one of these jackets may safely venture into a rough sea.

A cork spencer has lately been invented to save from drowning, in cases of shipwreck; which consists of a belt, containing refuse pieces of cork, or old bottle-corks, enclosed in any kind of covering, and fastened round the

body with tapes. The excellence of this consists in its cheapness, the whole being made for five shillings. See DROWNING.

COR-MASS, the name of a grand procession, said to have been established at Dunkirk during the dominion of Charles V. and renewed on St. John's day, the 24th of June. After the celebration of high mass, the procession, consisting of the several tradesmen of the town, began. Each person had a burning taper of wax in his hand; and after each company came a pageant, followed by the patron saint, usually of solid silver, richly wrought and adorned. The companies were followed by music; and after the musicians, the friars in the habits of their order, the secular priests, and then the abbot magnificently adorned, and preceded by the host. Machines likewise of various fantastical forms and devices, and as variously accoutred, formed a part of the show on this occasion; which has been described as one of the most superb and magnificent in the world.

CORN, in country affairs, the grain or seeds of plants separated from the spica or ear, and used for making bread. See HUSBANDRY.

CORN-LAWS. It is against the common law of England to buy or sell corn in the sheaf, before it is thrashed and measured: the reason whereof seems to be, because by such sale, the market is in effect forestalled. 3 Inst. 197.

Every person who shall sell or buy corn without measuring, or otherwise than by the Winchester measure, sealed and stricken by the brim, shall on conviction before one justice on the oath of one witness forfeit 40s. besides the whole of the corn so sold or bought, or the value thereof, half to the poor, and half to the informer.

On complaint to a justice, that corn has been bought, sold, or delivered, contrary to the act, the proof shall lie upon the defendant, to make it appear by oath of one witness, that he sold or bought the same lawfully: and if he shall fail therein, he shall forfeit as before mentioned, to be levied by distress and sale. 22 and 23 C. II. c. 8 and 12; and K. v. Arnold, T. 33 G. III.

And if any mayor, or other head officer, shall knowingly permit the same, he shall on conviction at the county sessions, forfeit 50*l.* half to the prosecuter and half to the poor, by distress and sale. For want of distress, to be imprisoned by warrant of the justices, till payment be made. 22 C. III. c. 8. s. 3.

The last acts now in force to regulate the returns of the prices of grain, are statutes 31 G. III. c. 30. 33. G. III. c. 65. By the former the statutes 1 Jac. II. c. 19: 1 W. and M. c. 12: 1 G. II. c. 12: 10 G. III. c. 39: 13 G. III. c. 43: 21 G. III. c. 50: and 29 G. III. c. 58, are all repealed; as also every provision in any other act regulating the importation of wheat, &c. except such as relate to the making of malt for exportation, and the exportation thereof. So much of the 15 Car. II, as prohibits the buying of corn to sell again, and the laying it up in granaries, is also repealed.

By the statutes of 31 G. III. c. 30, and 33 G. III. c. 65, bounties are granted on exportation at certain prices, and the exportation prohibited when at higher prices; the quantity of corn to be exported to foreign countries is settled: and the maritime counties of England are divided into districts. The exportation of corn is to be regulated in London, Kent, Essex, and Sussex, by the prices at the corn-exchange; the proprietors of which are to appoint an inspector of corn-returns, to whom weekly returns are to be made by the factors; and he is to make weekly accounts, and transmit the average price to the receiver of the returns, to be transmitted to the officers of the customs, and inserted in the London Gazette. The exportation in other districts and in Scotland, to be regulated by the prices at different appointed places, for which mayors, justices, &c. are to elect inspectors. Declarations are to be truly made by factors, of corn sold by them. Orders of council may regulate importation, &c. such orders to be laid before parliament. 32 Geo. III. c. 50. and 33 Geo. III. c. 3.

CORN, in medicine and surgery, a hard tumour like a flat wart, growing in several parts of the feet, especially upon the joints of the toes. This disorder is not unjustly attributed to the wearing of too strait or narrow-toed shoes, which never fail to produce these tubercles, especially if the person is obliged to stand or walk much, and in the summer time.

CORNEA TUNICA, in anatomy, the second coat of the eye; so called from its substance, which resembles the horn of a lanthorn. See ANATOMY.

CORNER-STONES, among builders, the two stones which stand one in each jaumb of a chimney. The breadth of each stone ought to be equal to that of the jaumb, and its face to be hollowed in the sweep of a circle; their height ought to reach from the hearth to the mantle-tree: they are commonly made of Ryegate or firestone.

CORNET, in the military art of the ancients, an instument much in the nature of a trumpet: when only it sounded, the ensigns were to march alone without the soldiers: whereas when the trumpet only sounded, the soldiers were to move without the ensigns. The cornets and buccinæ sounded the charge and retreat, and the cornets and trumpets sounded during the course of the battle.

CORNET is also a commissioned officer in a troop of horse or dragoons.

CORNICULARIUS, in Roman antiquity, an officer of the army, appointed to assist the military tribune in quality of lieutenant.

CORNUCOPIÆ, a genus of the digynia order, in the triandria class of plants, and in the natural method ranking under the 4th order, gramina. The involucrum is monophyllous, funnel-shaped, crenated, and multiflorous; the calyx bivalved; the corolla onevalved. There are two species.

CORNUS, *cornel tree, cornelian cherry*, or *dogwood*, a genus of the monogynia order, in the tetrandria class of plants, and in the natural method ranking under the 47th order, stellatæ. The involucrum is most frequently monophyllous; the petals above the receptacle of the fruit, four; the fruit itself a bilocular kernel. Of this genus there are 12 species; the most remarkable are the following: 1. The mas or cornelian cherry-tree, has an upright tree-stem, rising 20 feet high, branching and forming a large head, with oblong leaves, and small umbels of yellowish-green flowers, at the sides and ends of the branch-

es; appearing early in the spring, and succeeded by small, red, cherry-like, eatable, acid fruit. 2. The sanguinea, bloody-twig, or common dogwood, has an upright tree-stem, branching 10 or 12 feet high, having blood-red shoots, with oblong pointed nervous leaves two inches long; and all the branches terminated by umbellate white flowers, succeeded by black berries: of this there is a kind with variegated leaves. 3. The Florida or Virginian dog-wood, has a tree-stem branching 12 or 15 feet high, and fine red shoots, with large heart-shaped leaves; and the branches terminated by umbellate white flowers, having a large involucrum succeeded by dark-red berries. Of this species there are several varieties, chiefly distinguished by the colour of their berries, which are red, white, or blue. All the species may be propagated by seeds, which ought to be sown in autumn, otherwise they will lie a year in the ground. They may also be propagated by suckers, of which they produce great plenty, or by laying down the young branches.

CORNUTIA, a genus of the angiospermia order, in the didynamia class of plants, and in the natural method ranking under the 40th order, personatæ. The calyx is quinquedentated; the stamina longer than the corolla; the style very long; the berry monospermous. There are two species: the pyramidata has blue pyramidal flowers and hoary leaves. It grows plentifully in several of the islands of the West Indies, also at Campeachy, and at La Vera Cruz. It rises to the height of 10 or 12 feet, with rude branches, the leaves being placed opposite. The flowers are produced in spikes at the end of the branches, and are of a fine blue. They usually appear in autumn, and will sometimes remain in beauty for two months or more. It is propagated either by seeds or cuttings, and makes a fine appearance in the stove, but is too tender to bear the open air in this country.

COROLLA, among botanists, the most conspicuous part of a flower, surrounding the organs of generation. See Botany.

COROLLARY, is a consequence drawn from something already advanced or demonstrated: thus, it being demonstrated that a triangle which has two equal sides, has also two angles equal, this corollary will follow; that a triangle which has three sides equal, has also its three angles equal.

CORONA, among botanists, expresses any thing growing on the head of a seed. See Botany.

Corona *borealis*, the northern crown or garland, in astronomy, a constellation of the northern hemisphere, whose stars in Ptolemy's catalogue are 8, in Tycho's as many, and in Mr. Flamsteed's 31.

CORONAL, coronalis, in anatomy, the first suture of the scull. See Anatomy.

CORONARY *vessels*, vasa coronaria, in anatomy, certain vessels which furnish the substance of the heart with blood.

CORONATORE *eligendo*, in law, a writ that lies directed to the sheriff, out of the court of chancery, on the death or discharge of any coroner, commanding him to call the freeholders of the county for the election of a new coroner, and to certify to the said court both the election and the name of the party chosen, and to administer his oath to him, &c.

CORONER, a very ancient officer at the common law: he is called coroner, because he acts principally in the pleas of the crown; and coroners were of old time the conservators of the peace. This officer ought to be a sufficient person, that is, the most wise and discreet knight that best would and might attend upon such an office. St. Westm. c. 10. By the 14 Ed. III. st. 1, c. 8, no coroner shall be chosen unless he shall have land in fee sufficient in the same county wherein he may answer to all manner of people. The lord chief justice of the king's-bench is the sovereign coroner of the whole realm.

How elected. In ancient times, none under the degree of knight were chosen. 2 Inst. 32. 176. But as the chief intent was to prevent the choosing of persons of mean ability, it seems the design of it is sufficiently answered by choosing men of substance and credit; and as the constant usage for several ages past has been accordingly, it seems to be no objection at this day that the person chosen is not a knight. 2 Haw. 42, 43.

By the 28 Ed. III. c. 6. it is enacted, that all coroners of the counties shall be chosen in full county-courts, by the commoners of the said counties, of the most meet and lawful people that shall be found in the same, to execute the said office. But though they are chosen by the county, it must be pursuant to the king's writ, issuing out of and returnable into chancery; and none but freeholders have a voice at such election, for they only are suitors to the county-court. 2 Inst. 99. 2 Haw. 43, 44. When chosen they shall be sworn by the sheriff for the due execution of their office. 2 Hale. H. 55.

His duty in taking inquisitions. When any person comes to an untimely death, the township shall give notice thereof to the coroner; otherwise if the body be interred before he come, the township shall be amerced. Hale's Pl. 170. And if the township shall suffer the body to lie till putrefaction without sending for him, they shall be amerced. 2 Haw. 48.

When the coroner has received notice, he shall issue a precept to the constables of the four, five, or six next townships, to return a competent number of good and lawful men of their townships, to appear before him in such a place, to make an inquisition touching that matter. 4 Ed. I. st. 2. Or he may send a precept to the constable of the hundred. Wood, b. 4. c. 1. And there must be twelve jurors at the least. 2 Inst. 148. If the constable make no return, or if the jurors returned shall not appear, their defaults are to be returned to the coroner, and they shall be amerced before the judges of the assize. 2 H. H. 55.

The jury, after being sworn, is to be charged by the coroner to inquire, upon the view of the body, how the party came by his death. 2 H. H. 60.

Every coroner upon an inquisition before him found, whereby any person shall be indicted for murder or manslaughter, or as an accessary before the offence committed, shall put in writing the effect of the evidence given to the jury before him being material; and shall bind over the witnesses to the next general gaol-delivery to give evidence; and shall certify the evidence, the recognizance, and the inquisition or indictment before him taken and found, at or before the trial, on pain of being fined by the court. 1 & 2 P. & M. c. 13. s. 5.

But the coroner cannot inquire of accessaries after the

fact. He ought to inquire into the death of all persons dying in prison, that it may be known whether they died by violence or any unreasonable hardships.

His general power and duty. Besides his judicial place, the coroner has an authority ministerial, as a sheriff; namely, when there is a just exception taken to the sheriff, judicial process shall be awarded to the coroner for the execution of the king's writ. And in some special cases the king's original writ shall be immediately directed to him. 4 Inst. 271. He is bound to be present in the county-court to pronounce judgment of outlawry upon the exigent, after quinto exactus, at the fifth court, if the defendant do not appear. Wood, b. 4. c. 1.

It is his duty to inquire of treasure that is found, who were the finders, and likewise who is suspected thereof. He may also receive the appeal of an approver for an offence in the same, or in a different county; and if the appellee be in the same county, he may award process against him to the sheriff till it come to the exigent; but if the appellee be in a foreign county, the coroner cannot award process against him, but must leave it to the justices of a gaol-delivery, before whom the appeal is afterwards recorded. 2 Haw. 52.

Punishment for misdemeanour. Justices of assize and peace have power to inquire of and punish the defaults and extortions of coroners. 1 Hen. VIII. c. 7. and 25 Geo. II. c. 29. s. 6.

His fees. The coroner shall have for his fee, upon every inquisition taken upon the view of the body slain, 13*s.* 4*d.* of the goods and chattles of him that is the slayer and murderer, if he have any goods; and if he have no goods, of such amerciament as any township should happen to be amerced for the escape of the murderer. 3 Hen. VII. But as the said fee of 13*s.* 4*d.* is not an adequate reward for the general execution of the said office, therefore for every inquisition taken upon view of a body dying in gaol, the coroner shall have 20*s.*, and also 9*d.* for every mile he shall be compelled to travel from his usual place of abode to take such inquisition, to be paid by order of the justices in sessions, out of the county rates. 25 Geo. II. c. 29. s. 1.

CORONILLA, jointed podded colutea, a genus of the decandria order, in the diadelphia class of plants, and in the natural method ranking under the 32d order, papilionaceæ. The calyx is bilabiated, with two segments above coalited; the vexillum scarcely any longer than the alæ; the legumen much contracted between the seeds. To this genus Linnæus also joins the emerus, or scorpion sena, though Mr. Miller makes it a distinct species. There are 14 species, all plants of considerable beauty, with very bright yellow flowers. All of them, however, are rather too tender for this climate, except the emerus. This species rises with a shrubby stem, branching numerously six or eight feet high, with winged leaves of three pair of lobes, terminated by an odd one; and at the sides of the branches numerous long flower-stalks, each supporting two or three large yellow flowers, succeeded by longish pods; it is easily propagated by seeds, and likewise by layers or cuttings. The leaves of this plant are esteemed laxative, and used as a substitute for common sena in some parts of Europe. A dye is procured by fermentation from the leaves, like that of indigo.

CORPORA *carvernosa*, in anatomy. See ANATOMY.

CORPORAL, an inferior officer under a serjeant, in a company of foot, who has charge over one of the divisions, places and relieves sentinels, and keeps good order in the corps-de-garde: he also receives the word from the inferior rounds which pass by his corps-de-garde. This officer carries a fusee, and is commonly an old soldier. There are generally three corporals in each company.

CORPORAL *of a ship of war*, an officer under the master at arms, employed to teach the officers the exercise of small arms, or of musketry, and to attend at the gangway on entering ports, and observe that no spirituous liquors are brought into the ship, unless by express leave from the officers. He is also to extinguish the fire and candles at eight o'clock in winter and nine in summer, when the evening-gun is fired; and to walk frequently down in the lower decks in his watch, to see that there are no light but such as are under the charge of proper sentinels.

CORPORATION, a body politic, or incorporate, so called because the persons or members are joined into one body, and are qualified to take and grant, &c. Corporations are either spiritual or temporal; spiritual as bishops, deans, arch-deacons, parsons, vicars, &c. temporal as mayor, commonalty, bailiffs, burgesses, &c. And some corporations are of a mixed nature, composed of spiritual and temporal persons, such as heads of colleges and hospitals, &c. All corporations are said to be ecclesiastical or lay; ecclesiastical are either regular, as abbeys, priories, chapters, &c. or secular, as bishoprics, deanries, archdeaconries, &c. lay, as those of cities, towns, companies, or communities of commerce. Corporations may be established three different ways, viz. by prescription, letters patent, or act of parliament; but are most commonly established by patent or charter. London is a corporation by prescription: but though corporations may be by prescription, yet it shall be intended, that it did originally derive its authority by a grant from the king.

A corporation may be dissolved; for it is created upon a trust; and if it be broken, it is forfeited. No person shall bear office in any corporation but such as have received the sacrament, taken oaths, &c. A corporation cannot sue or appear in person, but by an attorney. Ordinances made by corporations to be observed on pain of imprisonment, forfeiture of goods, &c. are contrary to Magna Charta. Actions arising in any corporation may be tried in the corporation courts; but if they try actions not within their jurisdiction, and encroach upon the common law, they are liable to be punished for it. The corporation of the city of London is to answer for all particular misdemeanors committed in any of the courts of justice within the city, and for all other general misdemeanors committed in the city.

CORPS DE GARDE, a post in an army, sometimes under cover, sometimes in the open air, to receive a number of soldiers, who are relieved from time to time, and are to watch in their turns for the security of some more considerable post.

Corps-de-garde is frequently used for the men who watch in this post.

CORPS, in architecture, a term to signify any part

that projects or advances beyond the naked of a wall, serving as a ground for some decoration.

CORPSE. If any person steal the shroud or other apparel from a dead body, it will be a felony. 3 Inst. 110. 12 Rep. 113. But stealing the corps itself only, is not felony; but it is punishable as a misdemeanour, by indictment at common law. 2 Black. 236.

CORPULENCY, in medicine, the state of a person too much loaded with flesh or fat.

An excessive degree of corpulency or fatness becomes a disease, when the whole body, as well as the belly, is grown into such a bulk, that the actions, especially with respect to motion and respiration, are greatly impaired, if not entirely impeded. Boerhaave observes, that corpulency does not consist in the solids of the body being increased, but in their being distended to a greater pitch by the abundance of humours collected in them. Corpulency is supposed to arise from a copious, oily, soft blood, and is promoted by any thing that tempers and softens the blood; such are want of exercise and motion, an indolent life, too much sleep, nourishing foods, &c.

There is not a better remedy to reduce a corpulent habit, than acetum sciliticum drunk upon an empty stomach. Semen fraxini, or bird's-tongue as it is called, ʒj, drunk in a morning in a glass of wine, is very much commended as an effectual diuretic, and on that account abates corpulency. Borellus recommends the chewing of tobacco; but it is not safe for all persons to use it, lest it should throw them into a consumption. Dr. Flemming recommends from one to four grains of Castile soap to be taken at bed-time. Those that are naturally gross and fat, oftener die suddenly than other people. The most extraordinary instance of corpulency perhaps ever known, was that of Edw. Bright of Malden, in Essex, who, dying in Nov. 1750, at the age of 29 years, weighed 616 pounds; his waistcoat, with great ease, was buttoned round seven men of ordinary size.

CORPUS, in anatomy, a term applied to several parts of the animal structure, as corpus callosum, corpus cavernosum, &c.

Corpus callosum, a medullary part of the brain, which covers the whole lateral ventricles.

Corpus cavernosum, a cavernous substance, surrounding the vagina.

Corpus cum causa, in law, a writ issuing out of the chancery to remove both the body and record, touching the cause of any man lying for execution upon a judgment for debt, into the king's bench, there to lie till he has satisfied the judgment.

CORPUSCLE, in physics, a minute particle, or physical atom, being such as a natural body is made up of. By this word are not meant the elementary particles, but such, whether of a simple or compound nature, whose parts will not be dissipated by ordinary degrees of heat. Sir Isaac Newton, in the second book of his Optics, shows a way of assuming, with great accuracy, the size of the component corpuscles of bodies.

CORRECTION, in printing, the pointing out or discovering the faults in a printed sheet, in order to be amended by the compositor before it be printed off.

The corrections are placed on the margin of every page, against the line in which the faults are found; and there are different characters used to express different corrections: thus ꝺ is put for dele, to intimate that something, as a point, letter, word, &c. dashed in that line is to be taken out. If any thing is to be inserted, the place is to be marked thus ʌ and the thing to be inserted added in the margin. When there are two or more corrections in the same line, then they are all separated in the margin by little bars, thus | . If a space is omitted, its place is marked with a caret, and in the margin thus ‡‡. When a letter is inverted, it is expressed in the margin thus ⊙. When any thing is to be transposed it is directed thus, Extraordinary scarce ever fail of attainments exciting envy, for Extraordinary attainments scarce ever fail of exciting envy, and in the margin is added *tr.* If Italic characters are to be changed for Roman, or vice versa, a line is drawn thus — under the letters, and Rom. or Ital. is written in the margin. If a space, or an m or n quadrat, stick up, and print black, it is marked in the margin with a dash, thus | . If a word, sentence, or paragraph is entirely omitted, the place is marked with a caret, and in the margin is put the word *out.* If the letters of a word stand too far asunder, a line is drawn under them, and in the margin is put a crooked line or hook, thus ⌣. There are many other marks used in correcting, as ✓ for superior, *cap.* for capital, *l. c.* for lower case, &c.

CORRECTOR *of the staple*, a clerk belonging to the staple, whose business it is to write down and record the bargains that merchants make there.

Corrector, in medicine and pharmacy, an ingredient in a composition which guards against or abates the force of another. See Pharmacy.

CORRELATIVE, something opposed to another in a certain relation. Thus, father and son are correlatives. Light and darkness, motion and rest, are correlative and opposite terms.

CORROSION, in a general sense, the action of gnawing away, by degrees, the continuity of the parts of bodies. Acids corrode most natural bodies.

CORROSIVES, in surgery, are medicines which corrode whatever part of the body they are applied to: such are burnt alum, white precipitate of mercury, white vitriol, red precipitate of mercury, butter of antimony, and lapis infernalis.

CORRUGATOR. See Anatomy.

CORRUPTICOLÆ, in church-history, a sect of heretics, so called from their maintaining that the body of Christ was corruptible, that the fathers had owned it, and that to deny it was to deny the truth of our Saviour's passion.

CORRUPTION, the destruction, extinction, or at least cessation for a time, of the proper mode of existence of any natural body.

Corruption *of blood*, in law, an infection accruing to a man's state attainted of felony and treason, and to his issue; for as he loses all to the prince, &c. his issue cannot be heirs to him, nor to any other ancestor by him; and if he was noble, his heirs are rendered ignoble.

CORSELET, a little cuirass; or, according to others, an armour or coat made to cover the whole body; anciently worn by the pike-men, usually placed in the front and flanks of the battle, for the better resisting the enemy's assaults, and guarding the soldiers placed behind them.

CORTUSA, bear's-ear sanicle; a genus of the monogynia order, in the pentandria class of plants, and in the natural method ranking under the 21st order, preciæ. The corolla is wheel-shaped, with its throat like an elevated ring, the capsule unilocular, oval, and quinquevalved at the top. There are two species; both of them very low, flowery, herbaceous perennials, crowned by umbels of monopetalous wheel-shaped flowers, of a fine red colour. They are natives of mountainous rocky parts abroad, so must have a dry lean soil; or they may be kept in pots of dry sandy earth placed in the shade, and in the summer must be duly watered; and their propagation here is by slipping the roots in October.

CORUNDUM, a mineral, of which there are two species, the perfect and imperfect. Perfect corundumor sapphire is found in the East Indies, especially in Pegu and the Island of Ceylon; and it is most commonly crystallized. The crystals are of no great size; their primitive form, as has been demonstrated by Bournon, is a rhomboid whose angles are 86° and 94°, and which therefore is nearly rectangular. Sometimes it occurs in this form, though but seldom. Bournon has described no less than eight modifications of it.

The texture of the sapphire is foliated; but in the more perfect specimens the plates are separated with difficulty. Fracture conchoidal. It causes only a single refraction. Specific gravity from 3.207 to 4.161. Colour most frequently blue; sometimes red, purple, yellow, and green; and sometimes colourless: imperfect corundum is usually crystallized; sometimes found in amorphous masses. The figures of the crystals are the same as those of the last species; opaque, except when in very thin pieces; specific gravity from 3.710 to 4.180; colour grey, often with various shades of blue and green.

Mr. Chenevix obtained the following constituents from different specimens of corundum subjected to chemical analysis.

Imperfect corundum.

	From the Carnatic.	From Malabar.	From China.	From Ava.
Silica	5,0	7,0	2,25	6,5
Alumina	91,0	86,5	89,50	87,0
Iron	1,5	4,0	6,50	4,5
Loss	2,5	2,5	1,75	2,0
	100,0	100,0	100,00	100,0

Perfect corundum.

	Blue, or sapphire.	Red, or oriental ruby.
Silica	5,25	7,0
Alumina	92,00	90,0
Iron	1,00	1,2
Loss	1,75	1,8
	100,00	100,0

Mr. Klaproth's analysis of sapphire differs a little from the above, but his analysis of imperfect corundum agrees with it. He found the sapphire composed of

98.5 alumina
1,0 oxyd of iron
0.5 lime

100,0

CORUS, *Omer*, *Homer*, or *Chomer*, in the Jewish antiquities, a measure containing 10 baths, or 75 gallons and 5 pints, as a measure for things liquid, and 32 pecks and 1 pint, as a measure for things dry.

CORUSCATION, a glittering or gleam of light issuing from any thing. It is chiefly used for the electrical fluid when rendered visible, as in a flash of lightning, &c. There are methods of producing artificial coruscations, or sparkling fiery meteors, which will be visible not only in the dark but in the day time.

CORVUS, the raven or crow kind, in ornithology; a genus of birds of the order of picæ, the distinguishing characteristics of which are these: the beak is convex and cultrated; the nostrils are covered with bristly feathers; the tongue is forked and cartilaginous; and the feet are of the walking kind. The species are 19, the most remarkable of which are (see Plate XXXVI. Nat. Hist. fig. 144.)

1. The corax, or raven of English authors, weighs three pounds, and is about two feet two inches in length; the colour is black, finely glossed with a rich blue, the belly excepted, which is of a dusky colour. They are very docile birds, and may be trained up to fowling like hawks, or to fetch and carry like spaniels; they may be taught to speak like parrots; and, what is most extraordinary of all, they may be taught to imitate the human voice in singing. They have a great propensity to pilfer, often hiding things of value, to the great loss of the owner, without use to themselves. They frequent the neighbourhood of great towns, where they are useful in devouring the carcases and filth which would otherwise prove a nuisance. They, however, also destroy many living animals; such as rabbits, young ducks and chickens, and not unfrequently lambs which have been dropped in a weak state. In clear weather they fly in pairs to a great height, making a deep loud noise, different from the common croaking. Their scent is remarkably good, and they are very long lived. The raven builds her nest early in the spring, laying five or six eggs, of a pale bluish-green colour, spotted with brown.

2. The corone, or carrion-crow, in the form of its body agrees with the raven; also in its food, which is carrion and other filth. It will also eat grain and insects; and like the raven will pick out the eyes of animals; whence it was formerly distinguished from the rook, which feeds entirely on grain and insects, by the name of the gor, or gor-crow. Virgil says that its croaking forebodes rain; "Tum cornix plena pluviam vocat improba voce." It was also thought a bird of bad omen, especially if it happened to be seen on the left hand: "Sæpe sinistra cava prædixit ob ilice cornix." England breeds more of this kind of birds than any other country in Europe. But though the crow abounds in Britain, it is so rare in Sweden, that Linnæus speaks of it only as a bird that he once knew killed there. It lays the same number of eggs as the raven, and of the same colour. Immediately after deserting their young they go in pairs.—Both these birds are often found white or pied, an accident that befals black birds more frequent than any others. Mr. Pennant says, he has observed one entirely of a pale brown colour, not only in its plumage, but even in its bill and feet. The crow weighs about 20

ounces. Its length is 18 inches; its breath two feet two inches.

3. The frugilegus, or rook, is the corvus of Virgil; no other species of this kind being gregarious. It differs not greatly in its form from the carrion-crow; the most remarkable difference is in the nostrils and root of the bill; which parts in the crow are well clothed with feathers, but in the rook are bare, or covered only with some bristly hairs. This arises from its thrusting the bill into the earth continually, after the various worms and eruca of insects, on which it feeds; for it does not live on carrion, like the last species or the raven. Besides insects, it also feeds on all sorts of grain, to some inconvenience perhaps to the husbandman, but no doubt he is doubly repaid by the good done to him in extirpating the maggot of the chafer-beetle, which in some seasons destroys whole crops of corn by feeding on the roots. The rook is a gregarious bird, sometimes being seen in immense flocks, so as almost to darken the air. These flights they regularly perform morning and evening, except in breeding-time, when the daily attendance of both male and female is required for the use of incubation, or feeding the young; for it is observed that they do both by turns. As these birds are apt to form themselves into societies, such places as they frequent during the breeding-time are called rookeries; and they generally choose a large clump of the tallest trees, for this purpose, but make so great a litter, and such a perpetual chatter, that nothing but habit and a length of time can reconcile one to the noise. The eggs are like those of crows, but less, and the spots larger. They begin to build in March, and after the breeding season forsake their nest-trees, going to roost elsewhere, but have been observed to return to them in August. In October they repair their nests. In Britain they remain the whole year; yet we are told that both in France and Silesia they are birds of passage.

4. The cornix, or Royston crow, in its habits resembles the rook, feeding on insects, and flying together in great flocks; but is easily distinguished by its plumage; its back, breast, and belly, being ash-colour, inclining to light blue, and consequently much handsomer; it is also rather larger than the rook, weighing 22 ounces. In England it is a bird of passage, visiting that kingdom in the beginning of winter, and leaving it with the woodcocks. In the maritime parts they feed on crabs and shell-fish. They are very common in Scotland; in many parts of the Highlands, and in all the Hebrides, Orkneys, and Shetlands, it is the only species of genuine crow, the carrion and rook being unknown there. It breeds and continues in those parts the whole year round. In the Highlands they breed indifferently in all kinds of trees; lay six eggs; have a shriller note than the common crows; are much more mischievous; pick out the eyes of lambs, and even of horses when entangled in bogs. They are, therefore, in many places proscribed, and rewards given for killing them. For want of other food these birds will eat cranberries or other mountain berries.

5. The dauricus, or white-breasted crow, is in length about 12 inches; the bill is black; the head and throat are black, glossed with blue; the neck and breast white; the rest of the body, wings, and tail, blue-black; the legs of a lead-colour; the claws black. Pallas describes the same species, which he says came early in the spring in great flights from China, and the southern Monguls country, into the parts about the lake Baikal, but most frequent about the towns and villages on the river Lena, in which part the jackdaws and Royston crows are very seldom seen. They live chiefly on insects.

6. The monedula, or jackdaw, weighs nine ounces; the length 13 inches, the breadth 28. The head is large in proportion to its body; which Mr. Willughby says, argues him to be ingenious and crafty. It is a docile and loquacious bird. Jackdaws breed in steeples, old castles, and in high rocks, laying five or six eggs. Sometimes they have been known to breed in hollow trees near a rookery, and join those birds in their foraging parties. In some parts of Hampshire they make their nests in rabbit-holes. They also build in the interstices between the upright and transum stones of Stonehenge; a proof of the prodigious height of that stupendous antiquity, for their nests are placed beyond the reach of the shepherd-boys, who are always idling about this spot. They are gregarious birds, and feed on insects, grain, and seeds. These birds are frequently brought up tame; they have a practice of hiding that part of their food which they cannot eat; and often, along with it, they secrete small valuables, sometimes occasioning injurious suspicions of theft in servants or others not guilty.

7. The glandarius, or jay, is one of the most beautiful of British birds. The weight is between six and seven ounces; the length 13 inches. The forehead is white streaked with black; the head is covered with very long feathers, which it can erect at pleasure into the form of a crest; the whole neck, back, breast, and belly, are of a faint purple dashed with grey; the covert-feathers of the wings are of the same colour. The first quill-feather is black; the exterior webs of the nine next are ash-coloured; the interior webs dusky; the six next are black, but the lower sides of their exterior webs are white tinged with blue; the two next wholly black; the last of a fine bay-colour, tipt with black. Jays build chiefly in woods, making their nests of sticks, fibres of roots, and tender twigs; and lay five or six eggs, of the size of a pigeon's, cinereous olive marked with pale brown. The young keep with the old ones till the next pairing-time in spring, when they choose each his mate to produce their future progeny. In general they feed on acorns, nuts, seeds, and fruits of all kinds, but will sometimes destroy young chickens and eggs, and will also take away birds that have been caught in a trap, or entangled with birdlime. They are often kept in cages, and will talk pretty well.

8. The caryocatactes, or nutcracker, is somewhat less than the jackdaw: the bill is strong, straight, and black; the colour of the whole head and neck, breast and body, of a rusty brown; the crown of the head and rump are plain; the other parts marked with triangular white spots; the wings are black; the coverts spotted in the same manner as the body; the tail is rounded at the end, black tipt with white; the vent-feathers are white; the legs dusky. We find these birds scattered in many parts of Europe, but no where so plenty as in Germany. They visit England very seldom; and are also found in North America, but not near the sea-coasts.

9. The pica, or magpie, is in length above 18 inches,

and weighs eight or nine ounces. In manners it approaches the crow, feeding almost on every thing in turn, both animal and vegetable; and like that will kill young ducks and chickens, and suck the eggs. It builds its nest with art, making a thorny cover at top, leaving a hole in the side for admittance; lays six or seven pale-greenish eggs, thickly spotted with black. It is a crafty bird in every state, and, if brought up young, becomes exceedingly familiar; and will talk a great many sentences, as well as imitate every noise within hearing, like a parrot, but not so plain.

10. The graculus, or red-legged crow, is but thinly scattered over the northern world: no mention is made of it by any of the Faunists; nor do we find it in other parts of Europe, except Britain and the Alps. It is produced in the island of Candia in Asia; and it visits Egypt towards the end of the inundation of the Nile. Except in Egypt, it affects mountainous and rocky places; builds its nest in high cliffs or ruined towers; and lays four or five eggs, white spotted with a dirty yellow. It feeds on insects, and also on new-sown corn. They commonly fly high, make a shriller noise than the jackdaw, and may be taught to speak. It is a very tender bird, and unable to bear very severe weather; is of an elegant, slender make; active, restless, and thieving; much taken with glitter, and so meddling as not to be trusted where things of consequence lie. It is very apt to catch up bits of lighted sticks, so that there are instances of houses being set on fire by its means; on which account Camden calls it incendiaria avis. It is found in Cornwall, Flinshire, Caernarvonshire, and Anglesea, in the rocky cliffs along the shores. It is also found in Scotland as far as Strathnavern, and in some of the Hebrides. Its colour is wholly black, beautifully glossed over with blue and purple: the legs and bill are of a bright orange-colour inclining to red; the tongue is almost as long as the bill, and a little cloven; the claws are large, hooked, and black.

11. The cristatus, or blue jay, is much smaller than the common jay. The bill is black, and above an inch long: the head is crested and blue: a streak on each side of the head and throat are of a bluish white, and there is a spot of the same over the eye: the hind part of the neck and back is blue: the wings and tail the same; all the feathers of the last, except the two middle ones, tipped with white; the feathers of both it and the wings elegantly barred with black, and the greater coverts and second quills tipped with white: the breast is of a blossom-colour: the belly and under tail-coverts white: the legs are dusky brown: the tail is nearly as long as the rest of the bird. The colours of the female are less bright than those of the male. The species is said to be peculiar to North America, but not seen farther north than the town of Albany.

12. The canadensis is in length nine inches, and weighs two ounces. The bill is blackish, and not quite an inch long: the irides are black: the forehead and throat are of a dirty yellow-white; the hind-head and sides of a blackish brown: the upper parts of the body are brown: beneath, pale ash. These birds inhabit Canada; and are frequent near Hudson's bay, where they are called whiskijohn and whiskijack. They breed early in the spring; build in pine-trees; and have two, rarely three, young at a time. The eggs are blue. They are not gregarious. Their food is black moss, worms, and flesh. They are very bold pilfering birds, stealing from the traveller even salt meat; and devouring often the bait from the traps set for the martins, as soon as the persons who set them turn their backs. They lay up stores for winter; at which time they are seldom seen unless near habitations.

Corvus, the raven, in astronomy, a constellation of the southern hemisphere, wherein, according to Ptolemy and Tycho's catalogue, are seven stars; whereas the Britannic catalogue reckons no less than ten.

Corvus, in Roman antiquity, a military engine, or rather gallery, moveable at pleasure by means of pulleys, chiefly used in boarding the enemy's ships, to cover the men.

CORYBANTES, in antiquity, priests of the goddess Cybele, who, inspired with a sacred fury, danced up and down, tossing their heads, and beating on cymbals or brazen drums. They inhabited mount Ida, in the island of Crete, where they nourished the infant Jupiter, keeping a continual rattling with their cymbals, that his father Saturn, who had resolved to devour all his male offspring, might not hear the child's cries.

CORYBANTICA, in Grecian antiquity, a festival kept in honour of the corybantes.

CORYCOMACHIA, among the ancients, was a sort of exercise in which they pushed forwards a ball, suspended from the ceiling, and at its return either caught it with their hands, or suffered it to meet their body. Oribasius informs us it was recommended for extenuating too gross bodies.

(CORYDALIS, in botany, a genus of the diadelphia, hexandria class and order; there are five species, natives of Pennsylvania and New York. (u)

CORYLUS, the hazel, a genus of the polyandria order, in the monœcia class of plants; and in the natural method ranking under the 50th order, amentaceæ. The male calyx is monophyllous, scale-like, trifid, and uniflorous; there is no corolla; the stamina eight in number: the female calyx diphyllous and lacerated; no corolla; two styles; and an egg-shaped nut. There are three species: 1st. The corylus avellana (from Avellino, in Italy, where they were first cultivated), or hazel, of which the filbert is a variety. 2d. Corylus rostrata, or American cuckoldnut. 3d. Corylus columo, Constantinopolitan hazel. They are all of the large shrub kind, hardy and deciduous; and have several varieties valuable for their nuts, as also for their variety in large wildernesses and shrubberry works. They will prosper in almost any soil or situation, and turn to good account when growing in coppices to cut as underwood, and as poles for various uses; as hoops, spars, hurdles, handles to husbandry implements, walking-sticks, fishing-rods, &c. for which purposes they may be cut every fifth, seventh, or eighth year, according to the purposes to which they are designed. The best method of propagating them is by layers, though they may also be raised from the nuts.

The kernels of the fruit have a mild, farinaceous, oily taste, agreeable to most palates. Squirrels and mice are fond of them, as well as some birds, such as jays, nutcrackers, &c. A kind of chocolate has been prepared from them, and there are instances of their having been formed into bread. The oil expressed from them is little

inferior to the oil of almonds; and is used by painters, and by chemists, for receiving and retaining odours.

Evelyn tells us, that no plant is more proper for thickening of copses than the hazel, for which he directs the following expeditious method: Take a pole of hazel (ash or poplar may also be used) of 20 or 30 feet in length, the heads a little lopped, giving it a chop near the ground to make it succumb; this fastened to the earth with a hook or two, and covered with some fresh mould at a competent depth (as gardeners lay their carnations), will produce a great number of suckers, and thicken and furnish a copse speedily.

CORYMBIUM, a genus of the monogamia order, in the syngenesia class of plants, and in the natural method ranking under the 49th order, compositæ. The calyx is diphyllous, uniflorous, and prismatical; the corolla monopetalous and regular; there is one woolly seed below each floret. There are four species.

CORYNOCARPUS, a genus of the monogynia order, in the pentandria class of plants. The calyx is a pentaphyllous perianthium: the corolla consists of five roundish, erect, and hollow petals; the stamina five subulated filaments arising from the base of the petals; the antheræ are erect and oblong; the pericarpium a monospermous, turbinated, clavated nut. There is one species, a native of New Zealand.

CORYPHA, mountain palm, or umbrella-tree, a genus of the order of palmæ, belonging to the monœcia class of plants. The corolla is tripetalous; the stamina six, with one pistil; the fruit a monospermous plum. There are two species. The umbracula is a native of the West Indies, where it is called codda pana. It rises to a considerable height, and produces at the top many large, palmated, plaited leaves, the lobes of which are very long, and are placed regularly round the end of a long spiny footstalk, in a manner representing a large umbrella. The flowers are produced on a branched spadix, from a compound spatha or sheath; they are hermaphrodite, and each consists of one petal, divided into three oval parts, and contains six awl-shaped stamina, surrounding a short slender style, crowned with a simple stigma. The germen is nearly round, and becomes a large globular fruit of one cell, including a large round stone. These plums having a pleasant flavour are held in esteem by the Indians.

CORYPHÆNA, in ichthyology, a genus belonging to the order of thoracici. The head is declined and truncated; the branchiostege membrane has six rays; and the back-fin, runs the whole length of the back. There are twelve species, most of them natives of foreign seas. The most remarkable are the blue and parrot fishes, described by Mr. Catesby. The head of the first is of an odd structure, resembling that of the spermaceti whale: the mouth is small, each mandible armed with a single row of even teeth, so closely joined that they seem entire bones; the iris of the eye is red. On the back is a long pliant fin, somewhat indented on the edge; behind the gills are two fins, one under the abdomen and another behind the anus. The tail is forked; and the whole fish entirely blue. They are taken on the coasts of the Bahama islands, and in most of the seas between the tropics. The parrot-fish has a large mouth, paved as it were with blunt teeth, closely connected after the manner of the lupus marinus. The body is covered with large green scales; the eyes are red and yellow; the upper part of the head brown, the lower part and the gills blue, bordered with a dusky red; a streak of red extends from the throat behind the gills, at the upper end of which is a bright-yellow spot. The fins are five in number: one extending almost the length of the back, of a bay or cinnamon colour; there are two behind the gills, blended with black, green, and purplish colours, with the upper edge verged with blue; under the abdomen is another red fin verged with blue; under the anus extends another long narrow green fin, with a list of red through the middle of it. At the basis of the tail on each side is a large yellow spot. The tail is large, forked, and green; with a curved red line running through the middle parallel to the curve, and ending in two points. The fish is more esteemed for beauty than the delicacy of its taste. They are taken on the coasts of Hispaniola, Cuba, and the Bahama islands. See Plate XXXVI. Nat. Hist. fig. 145. Pl. XL. fig. 146.

COS, the *whetstone*, in natural history, a genus of vitrescent stones, consisting of fragments of an indeterminate figure, subopake and granulated. Of this genus there are several species, some consisting of rougher and others of smoother, or even of altogether impalpable, particles; and used not only for whetstones, but also for mill-stones and other similar purposes.

Cos TURCICA, *turkey-stone*, a species of stones of the garnet kind, belonging to the siliceous class. It is of a dull white, and often of an unequal colour; some parts appearing more compact than others. Its specific gravity is 2598: it strikes fire with steel, and effervesces with acids. Mr. Kirwan found that 100 parts of it contain 25 of mild calcareous earth (carbonate of lime), and no iron. Cronstedt is of opinion that there are probably two sorts of stones known by this name, as that described by Wallerius neither gives fire with steel nor effervesces with acids. It is used as a whetstone; and those of the finest grain are the best hones for the most delicate cutting tools, and even for razors, lancets, &c.

CO-SECANT, in geometry, the secant of an arch which is the complement of another to 90°. See TRIGONOMETRY.

COSHERING, a seignoral prerogative, whereby the lord and his followers lay and feasted themselves at his tenant's house.

COSINAGE, a writ that lies where the tresayle or great-grandfather is seized in his demesne, as of fee at the day of his death, of certain lands or tenements, and dies, and then a stranger enters, and abates; for then shall his heir have this writ of cosinage.

CO-SINE, in trigonometry, the sine of an arch, which is the complement of another to 90°. See TRIGONOMETRY.

COSMOGRAPHY, a description of the several parts of the visible world; or the art of delineating the several bodies according to their magnitudes, motions, relations, &c. It consists of two parts, astronomy and geography.

COSTIVENESS, *obstructio alvi*, in medicine, a preternatural detention of the fæces, with an unusual dry-

ness and hardness of them, and thence a suppression of their evacuation. See MEDICINE.

COSTS, in law. By the statute of Gloucester, 6 Ed. I. c. 1. it is provided that the demandant may recover against the tenant, the costs of his writ, together with his damage; and that this act shall hold place in all cases, when the party is to recover damages. 1 New. Abr. 511. Costs of the writ extend to all legal costs of suit, but not expenses of travel, loss of time, &c. 2 Inst. 288. When double damages are given by act of parliament, the costs shall be doubled also; for damages include costs. Str. 1048. Persons suing *in forma pauperis*, shall not pay costs. 3 Black. 400.

It is an action, wherein there can be no such certifying, as debt, assumpsit, trover, trespass for taking goods, trespass for spoiling goods, trespass for beating a servant whereby he lost his service, it is out of the statute, and the plaintiff may have full costs. Salk. 208. Where costs are allowed, it is not necessary for the jury to give them, but they may leave it to the court to do it, who are the best able to judge of what costs are fitting to be given. It is the course of the court of king's-bench, to refer the taxation of costs to the proper officer of the court, and not to make any special rules for such matters, except it be in extraordinary cases. 1 Lit. Abr. 338.

The matter of costs in equity, is not held a point of right, but merely discretionary, according to the circumstances of the case, as they appear more or less favourable to the party vanquished. 3 Black. 451. If costs be refused to be paid, an attachment lies. 1 Nels. Abr. 550. The king and any person suing to his use shall neither pay nor receive costs. Stat. 24 H. VIII. c. 8.

The 18 Geo. III. c. 19. authorizes any justice, who shall have heard and determined the matter of a complaint made before him to award such costs to be paid by either party and in such manner as to him shall seem meet, to the party injured: and if the person so ordered by the justice, shall not forthwith pay, or give satisfaction to the justice, the same shall be levied by distress: and if goods and chattels of such person cannot be found, the justice shall commit him to the house of correction for the place where such person shall reside; to be kept to hard labour for any time not exceeding one month, nor less than ten days; or till such sum, with the expenses attending the commitment, be first paid.

Provided, that upon the conviction of any person upon a penal statute, where the penalty shall be at or exceed the sum of 5*l.* the said costs shall be deducted by the justice, at his discretion, out of the penalty, so that such deduction shall not exceed one-fifth part of the penalty; and the remainder of the penalty shall be divided among the persons who would have been entitled to the whole thereof, if this act had not been made. Costs double or treble are allowed to defendants sued for acting under almost every statute relating to officers of justice, customs or other duties, highways, paving, &c. For more matter concerning costs, see Bac. Abr. & 6 Vin. Abr. tit. Costs.

COSTUME, a term among painters: thus, a painter must observe the costume; that is, he must make every person and thing sustain its proper character; and not only observe the story, but the circumstances, the scene of action, the country or place, and make the habits, arms, manners, proportions, and the like, to correspond.

COSTUS, in botany, a genus of the monandria-monogynia class of plants, the flower of which consists of three lanceolated, concave, equal petals, placed pretty erect; the fruit is a roundish, coronated, trivalvular capsule, with three cells, containing several triangular seeds. There are three species. The root of this plant, or the costus Arabicus in pharmacy, is an attenuant, a diuretic, and a sudorific: it is given in obstructions of the menses, and in chronic cases, in which there are infractions of the viscera: its dose is from ten grains to half a dram, but we seldom hear of its being given singly. It is used in the Venice treacle, mithridate, and caryocostine electuary. Costus must be chosen recent, dense, odorous, bitterish, and not carious.

CO-TANGENT, the tangent of an arch, which is the complement of another. See TRIGONOMETRY.

COTESIAN *theorem*, in geometry, an appellation used for an elegant property of the circle discovered by Mr. Cotes. The theorem is this:

If the factors of the binomial $a^{\mathcal{S}}+x$ be required, the index c being an integer number. With the centre O, (Plate XXXIX. Miscel. fig. 21,) and radius $AO=a$, describe a circle, and divide its circumference into as many equal parts as there are units in $2c$, at the points A, B, C, D, &c.; then in the radius, produced if necessary, take $OP=x$; and from the point P, to all the points of division in the circumference, draw the lines PA, PB, PC, &c.; so shall these lines taken alternately be the factors sought: viz.

$$\text{PB}\times\text{PD}\times\text{PF}\times\&c=a^{\mathcal{S}}+x^{\mathcal{S}},$$

and $\text{PA}\times\text{PC}\times\text{PE}\times\&c=a^{\mathcal{S}}-x^{\mathcal{S}}$, viz. $a^{\mathcal{S}}-x^{\mathcal{S}}$, or $x^{\mathcal{S}}-a^{\mathcal{S}}$, according as the point P is within or without the circle.

For instance, if $c=5$, divide the circumference into 10 equal parts, and the point P being within the circle, then will

$$\text{OA}^5+\text{OP}^5=\text{BP}\times\text{DP}\times\text{EP}\times\text{HP}\times\text{KP},$$

and $$\text{OA}^5-\text{OP}^5=\text{AP}\times\text{CP}\times\text{EP}\times\text{GP}\times\text{IP}.$$

In like manner, if $c=6$, having divided the circumference into twelve equal parts, then will

$$\text{OA}^6+\text{OP}^6=\text{BP}\times\text{DP}\times\text{FP}\times\text{HP}\times\text{KP}\times\text{MP},$$

$$\text{OA}^6-\text{OP}^6=\text{AP}\times\text{CP}\times\text{EP}\times\text{GP}\times\text{IP}\times\text{LP}.$$

The demonstration of this theorem may be seen in Dr. Pemberton's Epist. de Cotesii Inventis. See also Dr. Smith's Theoremata Logometrica et Trigonometrica, added to Cotes's Harm. Mens. pa. 114; De Moivre Miscel. Analyt. pa. 17; and Waring's Letter to Dr. Powell, pa. 39.

By means of this theorem, the author was enabled to make a farther progress in the inverse method of fluxions, than had been done before. But in the application of his discovery there still remained a limitation, which was removed by M. Demoivre.

COTICE, or *Cotise*, in heraldry, is the fourth part of the bend.

COTINUS. See RHUS.

COTTAGE, in law, a little house for habitation, without lands belonging to it, stat. 4 Edw. I. But by a

later statute, 31 Eliz. c. 7, no man may build a cottage unless he lays four acres of land to it, except in cities or market-towns, or within a mile of the sea, or for the habitation of miners, sailors, foresters, shepherds, &c.; excepting also cottages erected by justices of the peace for poor impotent persons. The above four acres of land must be freehold, and land of inheritance; copy hold, or lease for years, are not sufficient tenure by the statute.

COTTON, a soft downy substance found on the gossypium, or cotton-tree. See GOSSYPIUM. Cotton is separated from the seeds of the plant by a mill, and then spun and prepared for all sorts of fine work, as stockings, waistcoats, quilts, &c. With it they likewise make calico and muslin; and sometimes it is mixed with wool, sometimes with silk, and even with gold itself. The finest sort comes from Bengal and the coast of Coromandel. Cotton makes a very considerable article in commerce, and is distinguished into cotton-wool and cotton-thread. The first is brought mostly from the West India islands, and Smyrna: the most esteemed is white, long, and soft. Those who buy it in bales should see that it has not been wet, moisture being very prejudicial to it.

Of cotton-thread, that of Damas, called cotton-d'ounce, and that of Jerusalem, called bazas, have been the most esteemed; as also that of the West Indian islands. But with the help of the machines now in general use, we are able to spin it of almost any degree of fineness. Cotton of Siam is a kind of silky cotton in the Antilles, so called because the grain was brought from Siam. It is of an extraordinary fineness, even surpassing silk in softness. They make hose of it there, preferable to silk for their lustre and beauty. They sell at from 10 to 12 and 15 crowns a pair, but there are very few made unless for curiosity.

The manner of packing cotton as practised in the Antilles is thus: The bags are made of coarse cloth, of which they take three ells and a half each; the breadth is one ell and three inches. When the bag has been well soaked in water, they hang it up, extending the mouth of it to cross pieces of timber nailed to posts, fixed in the ground seven or eight feet high. He who packs it goes into the bag, which is six feet nine inches deep, or thereabout, and presses down the cotton, which another throws in, with hands and feet; observing to tread it equally every where, and putting in but little at a time. The best time of packing is in rainy moist weather, provided the cotton is under cover. The bag should contain from 300 to 320 pounds. The tare abated in the Antilles is three in the hundred.

COTTON-*spinning*, the art or process of reducing cotton-wool into yarn or thread.

The most simple method for this purpose, and the only one in use for a long time in this country, was by the hand, upon the well-known domestic machine called a one-thread wheel. But as the demand for cotton goods began to increase, other inventions were thought of for expediting this part of the manufacture. About 60 years ago, one Paul and others of London contrived an engine for a more easy and expeditious method of spinning cotton, and for which they obtained a patent; but the undertaking did not prove successful. Some years after, various machines were constructed by different persons for facilitating the spinning of cotton, but without producing any very material or lasting advantage. At length, about the year 1767, Mr. James Hargrave, a weaver in the neighbourhood of Blackburn in Lancashire, constructed a machine by which a great number of threads (from 20 to 80) might be spun at once, and for which he obtained his majesty's letters-patent. This machine is called a jenny, and is the best contrivance for spinning woof or shoot that has hitherto appeared. It is now commonly constructed for 84 threads; and with it one person can spin 100 English hanks in the day, each hank containing 840 yards.

Carding of COTTON, as a preparation for spinning, used formerly to be performed by the hand, with a single pair of cards, upon the knee: but this being a tedious method, ill suited to the rapid operations of the new spinning-machines, other methods were contrived for affording a quicker and more adequate supply. The first improvement for this purpose was likewise made by Mr. Hargrave; and consisted in applying two or three cards to the same board, and fixing them to a stool or stock; whence they obtained the name of stock-cards. With these one woman could perform two or three times as much work as she could do before in the common way. A still more expeditious method of carding, however, by what are commonly called cylinder-cards, was soon afterwards invented, and is that which is now most commonly practised: but as several persons lay claim to this invention, it is not easy to determine to whom in particular the merit of it is due.

The next and most capital improvements which this branch of manufacture received were from Mr. Arkwright, a native of Lancashire, afterwards sir Richard Arkwright of Cromford in Derbyshire. He first brought forward his new method of spinning cotton in 1768, for which he obtained a patent in 1769: he afterwards, in 1775, obtained a patent for engines which he had constructed to prepare the materials for spinning; though one of these patents, being challenged at law, was set aside some years before it expired. The result of Mr. Arkwright's different inventions and improvements, is a combination of machinery, by which cotton is carded, roved, and spun, with the utmost exactness and equality; and such a degree of perfection attained in spinning warp, as is not to be equalled in any other part of the world. To these improvements England is entirely indebted for the great extent of its cotton-manufactures; large buildings having been erected for that branch both in England and Scotland, many of which contain several thousands of spindles, each driven by one or more large water-wheels; and some of such extent as to spin at the rate of one thousand yards of twist or warp-yarn in a minute.

Other machines have been invented at different times, and a variety of improvements made by different mechanics and manufacturers; one of which in particular we must not omit to mention. It is called a mule, being a kind of mixture of machinery between the warp-machine of Mr. Arkwright and the woof-machine or hand-jenny of Mr. Hargrave; and was also invented in Lancashire. This machine promises to be of great use in spinning

cotton-yarn for muslins to a degree of fineness never before known in this country, being nearly equal in quality to those usually brought from India.

COTTUS, or *Bull-head*, in ichthyology, a genus belonging to the order of thoracici. The head is broader than the body, and the gill membrane has six rays. There are six species, of which the most remarkable are: 1. The gobio, or river-bullhead, very common in all our clear brooks: it lies almost always at the bottom, either on the gravel or under a stone: it deposits its spawn in a hole which it forms among the gravel, and quits it with great reluctance. It feeds on water-insects. This fish seldom exceeds the length of three inches and a half: the head is large, broad, flat, and thin at its circumference, being well adapted for insinuating itself under stones: on the middle part of the covers of the gills is a small crooked spine turning inwards. The eyes are very small, the irides yellow; the body grows slender towards the tail, and is very smooth. The colour of this fish is as disagreeable as its form, being dusky mixed with a dirty yellow; the belly is whitish. The taste, however, is excellent. 2. The cataphractus (See Plate XL. N. H. fig. 147) is very common on most of the British coasts. It seldom exceeds five inches and a half in length, and even seldom arrives at that size. The head is large, bony, and very rugged: the end of the nose is armed with four short upright spines; on the throat are a number of short white beards; the body is octagonal, and covered with a number of strong bony crusts divided into several compartments, the ends of which project into a sharp point, and form several echinated lines along the back and sides from the head to the tail. 3. The scorpius, or father-lasher, is not uncommon on the rocky coasts of England; it lurks under stones, and will take a bait. It seldom exceeds 8 or 9 inches in length. The head is large, and has a most formidable appearance, being armed with vast spines, which it can oppose to any enemy that attacks it, by swelling out its cheeks and gill-covers to a large size. The nose and space contiguous to the eyes are furnished with short sharp spines; the covers of the gills are terminated by exceeding long ones, which are both strong and very sharp-pointed. The mouth is large, the jaws covered with very small teeth; the roof of the mouth is furnished with a triangular spot of very minute teeth. This species is very frequent in the Newfoundland seas, where it is called scolping: it is also as common on the coast of Greenland, in deep water near the shore. It is a principal food of the natives, and the soup made of it is said to be agreeable as well as wholesome.

COTULA, *may-weed;* a genus of the polygamia superflua order, in the syngenesia class of plants. The receptacle is almost naked; the pappus marginated; the florets of the disc quadrifid, of the radius frequently none. There are 15 species, most of them herbaceous annuals, rising six or eight inches high, and adorned with yellow flowers. None of them are natives of this country, and most of them require artificial heat.

COTYLA, or *Cotyla*, in antiquity, a liquid measure among the Greeks, equal to the hemina of the Romans, containing half a sextary, or four acetabula: hence it appears that it contained ten ounces of wine, and nine of oil. It is observed that the cotula was used as a dry measure as well as a liquid one, from the authority of Thucydides, who in one place mentions two cotulæ of wine, and in another two cotulæ of bread.

COTYLEDON, *navel-wort;* a genus of the pentagynia order in the decandria class of plants: and in the natural method ranking under the 13th order, succulentæ. The calyx is quinquefid; the corolla monopetalous: there are five nectariferous scales at the base of the germen, and five capsules. There are nineteen species, most of them succulent perennials for the green-house; though some require to be kept in a stove. They rise from half a foot to a yard and a half high, and are adorned with yellow flowers growing in umbels. They are easily propagated, either by seed or cuttings of their branches.

COUCH, in painting, a term used for each lay or impression of colour, either in oil or water, with which the painter covers his canvas, wall, wainscot, or other matter to be painted. The word is also used for a lay or impression on any thing, to make it more firm and consistent, or to screen it from the weather. Thus, paintings are covered with a couch or varnish; a canvas to be painted must have two couches of size, before the colours are laid on; two or three couches of white lead are laid on wood, before the gold is applied. The leather-gilders lay a couch of water and whites of eggs on the leather, before they apply the gold or silver leaf. The gold wire-drawers also use the word couch for the gold or silver leaf, wherewith they cover the mass to be gilded or silvered. The gilders use the term couch, for the quantity of gold and silver leaves applied on the metals in gilding and silvering. It is often vulgarly pronounced coat.

COUCHANT, in heraldry, is understood of a lion, or other beast, when lying down, but with his head raised; which distinguishes the posture of couchant from dormant, wherein he is supposed quite stretched out and asleep.

COUCHE', in heraldry, denotes any thing lying along: thus, chevron chouché is a chevron lying sideways, with the two ends on one side of the shield, which should properly rest on the base.

COUCHING *of a cataract*, in surgery, one of the two chief methods of curing a cataract, by couching with the needle. See SURGERY.

COVENANT, the agreement or consent of two or more by deed in writing, sealed and delivered; whereby either, or one of the parties, promises to the other, that something is done already, or shall be done afterwards: he that makes the covenant, is called the covenantor, and he to whom it is made the covenantee. Shep. Touch. 160.

A covenant is generally either in fact, or in law. In fact, is that which is expressly agreed between the parties, and inserted in the deed. In law, is that covenant which the law intends and implies, though it be not expressed in words; as if a lessor demise and grant to his lessee, an house or lands for a certain term, the law will intend a covenant on the lessor's part, that the lessee shall, during the term, quietly enjoy the same against all incumbrances. 1 Inst. 384.

COVENANT TO STAND SEISED TO USES, is when a man that has a wife, children, brother, sister, or kindred, by covenant in writing under hand and seal agrees, that for their, or any of their provision or preferment, he or his

heirs, will stand seised of land to their use, either in fee-simple, fee-tail, or for life.

CO-VERSED SINE, in geometry, the remaining part of the diameter of a circle, after the versed sine is taken from it. See TRIGONOMETRY.

COVERT WAY, or *Corridor*, in fortification, a space of ground, level with the field, on the edge of the ditch, three or four fathoms broad, ranging quite round the half-moons, and other works toward the country. It has a parapet raised on a level, together with its banquets and glacis. The greatest effort in sieges, is to make a lodgment on the covert-way, because the besieged usually palisade it along the middle, and undermine it on all sides.

COVERTURE, in law, is applied to the condition of a married woman, who by the laws of England is sub potestate viri, and therefore disabled to make bargain with any, to the prejudice of herself or her husband, without his assent and privity, or at least without his allowance and confirmation.

COUGH, *tussis*, in medicine, a convulsive motion of the diaphragm, muscles of the larynx, thorax, and abdomen, violently shaking, and expelling the air that was drawn into the lungs by inspiration. See MEDICINE.

COVIN, is a deceitful assent or agreement between two or more, to the prejudice of another. As if a tenant for term of life, or tenant in tail, will secretly conspire with another, that the other will recover against the tenant for life, the lands which he holds, &c. in prejudice of him in the reversion.

COULTER, is husbandry, an iron instrument, fixed in the beam of a plough, and serving to cut the edge of each furrow.

COUNCIL, *Common*, in the city of London, is a court wherein are made all bye-laws which bind the citizens. It consists, like the parliament, of two houses: an upper, composed of the lord-mayor and aldermen; and a lower, of a number of common-councilmen chosen by the several wards, as representatives of the body of the citizens.

COUNCIL, *Privy*, the executive part of the civil government of Great Britain. It is composed of eminent persons, the number of whom is at the sovereign's pleasure, who are bound by oath to advise the king to the best of their judgment, with all the fidelity and secrecy that becomes their station. The king may declare to, or conceal from, his privy-council whatever he thinks fit; and has a select council out of their number commonly called the cabinet-council. (generally the principal officers of state) with whom his majesty determines such matters as are most important, and require the utmost secrecy. All proclamations from the king and the privy-council ought to be grounded on law, otherwise they are not binding to the subject. Privy-counsellors, though but gentlemen, have precedence of all the knights and younger sons of barons and viscounts, and are styled right honourable.

COUNCIL *of war*, an assembly of the principal officers of an army or fleet, occasionally called by the general or admiral to concert measures for their conduct with regard to sieges, retreats, engagements, &c.

COUNCIL, in church-history, an assembly of prelates and doctors, met for the regulating matters relating to the doctrine, or discipline, of the church.

COUNCIL, *œcumenical* or *general*, is an assembly which represents the whole body of the universal church. The Romanists reckon eighteen of them: Bullinger, in his treatise de Conciliis, six; Dr. Prideaux, seven; and bishop Beveridge has increased the number to eight, which, he says, are all the general councils which have ever been held since the time of the first christian emperor. They are as follows: 1. The council of Nice, held in the reign of Constantine the great, on account of the heresy of Arius. 2. The council of Constantinople, called under the reign and by the command of Theodosius the Great, for much the same end that the former council was summoned. 3. The council of Ephesus, convened by Theodosius the Younger, at the suit of Nestorius. 4. The council of Chalcedon, held in the reign of Martianus, which approved of the Eutychian heresy. 5. The second council of Constantinople, assembled by the emperor Justinian, condemned the three chapters taken out of the books of Theodorus of Mopsuestia, having first decided that it was lawful to anathematize the dead. Some authors tell us, that they likewise condemned the several errors of Origen about the Trinity, the plurality of worlds, and the pre-existence of souls. 6. The third council of Constantinople, held by the command of Constantine Pogonatus the emperor, in which they received the definitions of the first five general councils, and particularly that against Origen and Theodorus of Mopsuestia. 7. The second Nicene council. 8. The fourth council of Constantinople, assembled when Lewis II. was emperor of the West. The regulations which they made are contained in twenty-seven canons.

COUNSEL, *for prisoners*. The judges never scruple to allow a prisoner counsel, to instruct him what questions to ask, or even to ask questions for him with respect to matters of fact; for as to matters of law, arising on the trial, they are entitled to the assistance of a counsel. 4 Black. 355.

COUNSELLOR, or COUNSEL, one retained by a client, to plead his cause in a court of judicature. A counsellor in law retained, has a privilege to enforce any thing which he is informed of by his client, and to give it in evidence, it being pertinent to the matter in question, and not to examine whether it is true or false; but it is at the peril of him who informs him; for a counsellor is at his peril to give in evidence, that which his client informs him, being pertinent to the matter in question, otherwise action upon the case lies against him by his client. Cro. Jac. 90.

The fees to counsellors are not in the nature of wages or pay, or that which we call salary or hire; which are duties certain, and grow due by contract for labour or service; but what is given them, is honorium, not merces; being a gift, which gives honour as well to the taker as the giver: nor is it certain or contracted; for no price or rate can be set upon counsel, which is invaluable and inestimable, so as it is more or less according to the circumstances, namely, the ability of the client, the worthiness of the counsellor, the weightiness of the cause, and the custom of the country. It is a gift of such a nature, that the able client may not neglect to give it, without ingratitude, for it is but a gratuity or token of thankfulness: yet the worthy counsellor may not demand it without doing wrong to his reputation. Præf. to Dav. Rep. 22, 23.

COUNT, *comes*, a nobleman who possesses a domain

erected into a county. The dignity is a medium between that of a duke and a baron. See EARL. Counts were originally lords of the court, or of the emperor's retinue, and had their name comites a comitando. Eusebius tells us, that Constantine divided them into three classes: of the two first the senate was composed: those of the third had no place in the senate, but enjoyed several other privileges of senators. There are counts that served on land, others at sea; some in a civil, and some in a legal capacity. The quality of count is now no more than a title which a king grants upon erecting a territory into a county, with a reserve of jurisdiction and sovereignty to himself. A count has a right to bear on his arms a coronet adorned with three precious stones, and surmounted with three large pearls, whereof those in the middle and extremities of the coronet advance above the rest.

COUNT, in law, signifies the original declaration of complaint in a real action, as a declaration is in a personal one.

COUNT-WHEEL, in the striking part of a clock, a wheel which moves round once in twelve or twenty-four hours.

COUNTER-APPROACHES, in fortification, lines and trenches made by the besieged in order to attack the works of the besiegers, or to hinder their approaches.

COUNTER-APPROACH, *line of*, a trench which the besieged make from their covered way to the right and left of the attacks, in order to scour the enemies' works. This line must be perfectly enfiladed from the covered way and the half-moon, that it may be of no service to the enemy, in case he gets possession of it.

COUNTER-BATTERY, is a battery raised to play upon another to dismount the guns.

COUNTER-BOND, a bond of indemnification given to one who has given his bond as a security for another's payment of a debt, or the faithful discharge of his office or trust.

COUNTER-CHARGED, in heraldry, is when any field or charge is divided or parted by any line or lines of partition, consisting all interchangeably of the same tinctures.

COUNTER-DEED, a secret writing either before a notary or under a private seal, which destroys, invalidates, or alters, a public one.

COUNTERFEITS, in law, are persons that obtain any money or goods by counterfeit letters or false tokens; who, being convicted before justices of assize or of the peace, &c. are to suffer such punishment as shall be thought fit to be inflicted under death, as imprisonment, pillory, &c.

COUNTER-FACED, or CONTRE-FACE', in heraldry, is the same that we call barry per pale counterchanged; but then the number of panes into which the field is divided, is always specified.

COUNTER-FOIL, or COUNTER-STOCK, in the exchequer, that part of a tally which is kept by an officer of the court.

COUNTER-FORTS, spurs or buttresses serving as props to a wall subject to bulge or to be thrown down.

COUNTER-FUGUE, a fugue in which the subjects move in contrary directions.

COUNTER-GAGE, in carpentry, a method used in measuring the joints. For example, they transfer the breadth of a mortis to the place in the timber where the tenon is to be, in order to make them fit each other.

COUNTER-GUARD, in fortification, is a work raised before the point of a bastion, consisting of two long faces parallel to the faces of the bastion, making a salient angle: they are sometimes of other shapes, or otherwise situated.

COUNTERMAND, in the English law, is where a thing before executed is by some act or ceremony afterwards made void by the party that did it.

COUNTERMARCH, in military affairs, a change of the face or wings of a battalion, by which means those that were in the front come to be in the rear. It also signifies returning or marching back again.

COUNTER-MARK, a mark put upon goods that have been marked before. It is also used for the several marks put upon goods belonging to several persons, to show that they must not be opened but in the presence of them all or their agents. In Goldsmith's work, the countermark is the mark punched upon the work at the hall, to show that the metal is standard.

Counter-mark of a medal is a mark added to it a long time after its being struck. It is sometimes an emperor's head, sometimes a cornucopia, &c. Counter-marks are distinguished from the monograms in this, that being struck after the medal, they are indented; whereas the monograms being struck at the same time with the medals, have a little relievo.

COUNTER-MINE, in war, a well and gallery driven and sunk till it meets the enemy's mine, to prevent its effect.

COUNTER-PALED, *contre-pallé*, in heraldry, is when the escutcheon is divided into 12 pales parted per fesse, the two colours being counterchanged; so that the upper are of one colour, and the lower of another.

COUNTER-PART, in music, denotes one part to be applied to another. Thus the bass is said to be a counterpart to the treble. In law, it is the duplicate or copy of any indenture or deed.

COUNTER-PASSANT, is when two lions are in a coat of arms, and the one seems to go quite the contrary way from the other.

COUNTER-PLEA, in law, a cross or contrary plea; particularly such as the demandant alleges against a tenant in courtesy or dower, who prays the king's aid, &c. for his defence.

COUNTERPOINT, in music, the act of combining and modulating consonant sounds. This branch of musical practice derives its name from the points formerly employed in composition instead of notes, and may be understood point against point, or note against note. This was the primitive state of counterpoint, which has since been called plain or simple counterpoint, in contradistinction to the modern figured or florid counterpoint, in which, for the purpose of beautifying the melody and enriching the general effect, many notes in succession are frequently set in one part against a single note in another.

COUNTER-QUARTERED, in heraldry, denotes the escutcheon, after being quartered, to have each quarter again divided into two.

COUNTER-SALIENT, is when two beasts are borne in a coat leaping from each other directly the contrary way.

COUNTERCARP, in fortification, is properly the exte-

rior talus or slope of the ditch; but it is often taken for the covered way and the glacis. In this sense we say, the enemy have lodged themselves on the counter-scarp.

Counterscarp, *angle of the*, is that made by two sides of the counterscarp, meeting before the middle of the curtin.

Countersigning, the signing the writing of a superior in quality of secretary. Thus charters are signed by the king, and countersigned by a secretary of state or lord chancellor.

Counter-swallowtail, in fortification, an outwork in form of a single tenaille, wider at the gorge than the head.

Counter-tenor, high tenor, a term applied to the highest natural male voice.

Counter-tripping, is when two beasts are borne in a coat in a walking posture, the head of the one being next the tail of the other.

Counters *in a ship*, are two. 1. The hollow arching from the gallery to the lower part of the straight piece of the stern, is called the upper counter. 2. The lower counter is between the transom and the lower part of the gallery.

COUNTY, in geography, originally signified the territory of a count or earl, but now it is used in the same sense with shire, and contains a circuit or portion of the realm, into which the whole land is divided, for the better government of it, and the more easy administration of justice; so that there is no part of this nation which is not within some county; and every county is governed by an annual officer, whom we call a sheriff. Fortescue, c. 24. See Sheriff.

Counties *palatine*, are those of Chester, Durham, and Lancaster. Of these three, the county of Durham is now the only one remaining in the hands of a subject; for the earldom of Chester was united to the crown by king Henry III. and has ever since given title to the king's eldest son. And the county-palatine or duchy of Lancaster, in the reign of king Henry IV., was by act of parliament vested in the king, and his heirs, kings of England, for ever. 1 Black. 118.

There is a court of chancery in the counties-palatine of Lancaster and Durham, over which there are chancellors; that of Lancaster called the chancellor of the duchy: and there is a court of exchequer at Chester, of a mixed nature, for law and equity, of which the chamberlain of Chester is judge. There are also a chief justice of Chester, and other justices in the other counties-palatine, to determine civil actions and pleas of the crown. In all of these the king's ordinary writs are of no force; and the judges of assize, who sit within these franchises, sit by virtue of a special commission from the owners thereof, and under the seal thereof, and not by the usual commission under the great seal of England. 3 Black. 79.

County-corporate, a title given to several cities on which the English monarchs have thought proper to bestow extraordinary privileges, annexing to them a particular territory of land or jurisdiction; as the county of Middlesex annexed to the city of London, the county of the city of York, the county of the city of Bristol, &c.

County-court. This was formerly a court of great dignity and splendour; the bishop and the earl, with the principal gentlemen of the shire, sitting therein to administer justice, both in lay and ecclesiastical causes. But its dignity was much impaired when the bishop was prohibited, and the earl neglected, to attend it: and in modern times, as the proceedings are removeable hence into the king's superior courts, by writ of pone or recordare, this has occasioned the business of the county-court in a great measure to decline.

By the 2d and 3d Ewd. VI. c. 25, no county-court shall be longer deferred than one month from court to court; so that the county-court shall be kept every month, and not otherwise; and only 28 days shall be reckoned to the month. 2 Inst. 74. And it may be kept at any place within the county, unless restrained by statute. Wood, c. 4. c. 1.

The suitors, that is, the freeholders, are the judges of this court; except that in re-disseisin, by the statute of Merton, the sheriff is judge.

The jury in this court ought to be freeholders; but the quantum of their estate is not material.

This court shall hold pleas between party and party, where the debt or damage is under 40*s*. 4 Inst. 266. But in replevin the sum may exceed 40*s*. Id.

It has not cognizance of trespass *vi et armis*, because a fine is thereby due to the king, which it cannot impose. Id. But by virtue of a writ of justices, the court may hold plea of trespass *vi et armis*, and of any sum, or of all actions personal above 40*s*. Id.

Causes may be removed from this court by a writ of recordare, issuing out of the chancery, directed to the sheriff, commanding him to send the plaint that is before him in his county-court (without writ of justices) into the court of king's bench of common pleas, to the end that the cause may be there determined; whereupon the sheriff is to summon the other party to be in that court (into which the plaint is to be sent) at a day certain; and he is to make certificate of all this under his own seal, and the seal of the four suitors of the same court. Read, County-court.

Causes may also be removed by pone, which differs in nothing from a recordare, except that it removes such suits as are before the sheriff by writ of justices, and a recordare is to remove the suit that is by plaint only, without writ. Id. And though the plea be discontinued in the county, yet the plaintiff or defendant may remove the plaint into the common pleas or king's bench, and it shall be good, and he shall declare upon the same. Id.

County-rate. By the 12th Geo. II. c. 29. the justices at their general or quarter sessions, or the greater part of them (and by 13 Geo. II. c. 18. justices of liberties and franchise not subject to county-commissioners,) shall have power to make one general county-rate, to answer all former distinct rates, which shall be assessed on every parish, &c. and collected and paid by the high constables of hundreds to treasurers appointed by the justices, which money shall be deemed the public stock, &c.: but appeal lies by the churchwardens and overseers against the rate of any particular parish. 22 Geo. III. c. 17. This rate is,—

For the repairing of bridges and highways thereto adjoining; and salaries for the surveyors of bridges; for building and repairing county-gaols; for repairing shire-halls; for the salary of the master of the house of correc-

tion, and relieving the weak and sick in his custody; for the relief of the prisoners in the king's bench and marshalsea prisons, and of poor hospitals in the county, and of those who shall sustain losses by fire, water, the sea, or other casulties, and other charitable purposes for the relief of the poor, as the justices in sessions shall think fit; for the relief of the prisoners in the county-gaol; for the preservation of the health of the prisoners; for the salary of the chaplain of the county-gaol; for setting prisoners to work: salary of persons making returns of the prices of corn; for charges attending the removal of any of the said general county-rates by certiorari; for money for purchasing lands at the ends of county-bridges; for charges of rebuilding or repairing houses of correction, and for fitting up and furnishing the same, and employing the persons sent thither; for charges of apprehending, conveying, and maintaining, rogues and vagabonds; for charges of soldiers' carriages over and above the officers' pay for the same, by the several yearly acts against mutiny and desertion, and by the militia act; for the coroner's fee of 9*d*. a mile for travelling to take an inquisition, and 20*s*. for taking it; for charges of carrying persons to the goal or house of correction; for the gaoler's fees for persons acquitted of felony or discharged by proclamation; for charges of prosecuting and convicting felons; for charges of prosecuting and convicting persons plundering shipwrecked goods; for charges of maintaining the militia-men's families by the several militia acts; for charges of bringing insolvent debtors to the assizes, in order to their discharge, if themselves are not able to pay; for the charges of transporting felons, or conveying them to the places of labour and confinement; for charges of carrying parish apprentices, bound to the sea service, to the port to which the master belongeth.

By the 12th Geo. II. c. 29, the churchwardens and overseers shall, in 30 days after demand made, out of the money collected for relief of the poor, pay the sums so assessed on each parish or place: and if they shall neglect or refuse so to pay, the high-constable shall levy the same by distress and sale of their goods, by warrant of two or more justices residing in or near such parish or place. Where there is no poor-rate, the justices, in their general or quarter sessions, shall by their order direct the sum assessed on such parish, township, or place, to be rated and levied by the petty constable or other peace-officer, as money for the relief of the poor is by law to be rated or levied. The high-constables, at or before the next session respectively after they have received the money, shall pay the same to the treasury; and the money so paid shall be deemed the public stock: and the said high-constables shall deliver in a true account on oath (if required) of the money by them received, before the said justices at their general or quarter sessions. The treasurer shall pay so much of the money in his hands to such persons, as the justices in session shall from time to time appoint, for any uses and purposes to which the public stock of any county, city, division, or liberty, is or shall be applicable; and shall deliver in a true account on oath (if required) of his receipts and disbursements to the justices at every general or quarter session, and also the proper vouchers for the same, to be kept amongst the records of the sessions: and the discharge of the said justices, by their order at their general or quarter session, shall be a sufficient discharge to the treasurer: and no new rate shall be made until it appears by the treasurer's accounts or otherwise, that three-fourths of the money collected has been expended for the purpose aforesaid. If the churchwardens and overseers of any parish or place shall think such parish or place is overrated, they may appeal to the next general or quarter session.

COUP-DE-MAIN, in military affairs, implies a desperate resolution in all small expeditions of surprise, &c. The favourable side of the proposed action must ever be viewed; for if what may happen, arrive, or fall out, is chiefly thought upon, it will at the very best, not only greatly discourage, but in general it will produce a total failure. The very name of an expedition implies risk, hazard, precarious warfare, and a critical but desperate operation or coup-de-main.

COUP-*d'œil*, in a military sense, signifies that fortunate aptitude of eye in a general or other officer, by which he is enabled at one glance on the map to see the weak parts of an enemy's country, or to discern the strong ones of his own. By possessing a ready coup-d'œil, a general may surmount the greatest difficulties, particularly in offensive operations. On a small scale this faculty is of the greatest utility. Actions have been recovered by a sudden conception of different openings upon the enemy, which could only be ascertained by a quick and ready eye, during the rapid movements of opposing armies.

COUPED, *coupé*, in heraldry, is used to express the head or any limb of an animal cut off from the trunk smooth; distinguishing it from that which is called erased, that is, forcibly torn off, and therefore is ragged and uneven.

COUPED is also used to signify such crosses, bars, bends, chevrons, &c. as do not touch the sides of the escutcheon, but are, as it were, cut off from them.

COUPLE-CLOSS, in heraldry, the fourth part of a chevron, never borne but in pairs, except there is a chevron between them.

COUPURE, in fortification, are passages sometimes cut through the glacis, of about 12 or 15 feet broad, in the re-entering angle of the covert-way, to facilitate the sallies of the besieged. They are sometimes made through the lower curtain, to let boats into a little haven built on the rentrant angle of the counterscarp of the out works.

COURAP, the modern name for a distemper very common in Java and other parts of the East Indies. It is a sort of herpes or itch on the arm-pits, groins, breast and face: the itching is almost perpetual; and the scratching is followed by great pain and a discharge of matter, which makes the linen stick so to the skin as not easily to be separated without tearing off the crust. Courap is a general name for any sort of itch; but this distemper is thus called by way of eminence. It is so contagious that few escape it. For the cure, gentle and repeated purging is used, and externally the ointment of nitrated quicksilver.

COURSE, in navigation, the point of the compass or horizon which a ship steers on, or the angle which the rhumb-line on which it sails makes with the meridian; being sometimes reckoned in degrees, and sometimes in points of the compass.

When a ship sails either due north or south, she sails on a meridian, makes no departure, and her distance and difference of latitude are the same.

When she sails due east or west, her course makes right-angles with the meridian, and she sails either upon the equator or a parallel to it; in which case she makes no difference of latitude, but her distance and departure are the same.

But when the ship sails between the cardinal points, on a course making always the same oblique angle with the meridians, her path is then the loxodromic curve, being a spiral cutting all the meridians in the same angle, and terminating in the pole.

COURSE, in architecture, a continued range of stones, level or of the same height throughout the whole length of the building.

COURSES, in a ship, the mainsail and foresail: when the ship sails under them only, without lacing on any bonnets, she is then said to go under a pair of courses. To sail under a main course and bonnets, is to sail under a mainsail and bonnet.

COURT. A court is defined to be a place appropriated to the judicial administration of justice. The law has appointed a considerable number of courts, some with a more limited, others with a more extensive jurisdiction; some of these are appropriated to inquire only, others to hear and determine; some to determine in the first instance, others upon appeal and by way of review.

The most general division of our courts is into such as are of record, or not; those of record are again divided into such as are supreme, superior, or inferior.

A court that is not a court of record, cannot impose any fine on an offender, nor award a capias against him, nor hold plea of debt or trespass, if the debt or damages amount to 40*s.*; nor of trespass done *vi et armis*, though the damages are laid to be under 40*s.*

COURT-BARON, is a court which every lord of the mannor (anciently called the barons) has within his own precincts. This court is an inseparable ingredient of every manor; and if the number of the suitors should so fail as not to leave sufficient to make a jury or homage, that is, two tenants at the least, the manor itself is lost. 2 Black.

The court-baron is of two natures: the one is a customary court, appertaining to the copyholders or other customary tenants, and of this the lord or his steward is the judge; the other is a court of common law, and is before the freeholders who owe suit and service to the manor, the steward being rather register than judge.

The copyholders, or customary court, is for grants and admittances upon surrenders and descents, on presentment of the homage or jury. The homage may inquire of the death of tenants after the last court, and who is the next heir; of fraudulent alienation of lands, to defeat the lord of his profits; of rent or service withdrawn; of escheats and forfeitures; of cutting down trees without licence or consent; of suit not performed at the lord's mill; of waste by tenant for life; of surcharge of common; of trespass in corn, grass, meadow, woods, hedges; of pound-breach; of removing mere-stones and land-marks; of by-laws not observed, and the like. The method of punishment is by amercement.

COURT *of chancery*. See CHANCELLOR, and CHANCERY.

COURT *of chivalry*, otherwise called the marshal court, the judges of which were the lord constable of England and the earl marshal of England; but since the extinguishment of the hereditary office of constable in the reign of Henry VIII. this court has been holden before the earl marshal only; and if it exceed its jurisdiction, it may be prohibited by the common law courts. 2 Haw. 602. It seems at this day to have a jurisdiction as to disputes concerning precedency and points of honour and satisfaction therein; and may proceed against persons for falsely assuming the name and arms of honourable persons. 2 Haw. 11. This court is to be governed by its own usages, as far as they go, and in other cases by the civil law; but since it is no court of common law, no condemnation in it causes any forfeiture of lands or corruption of blood; neither can an error in it be remedied by a writ of error, but only by appeal to the king; yet the judges of the common law take notice of its jurisdiction, and give credit to a certificate of its judges.

COURT *christian*, so called because, as in secular courts, the king's laws sway and decide causes, so in ecclesiastical courts, the laws of Christ should rule and direct; for which cause the judges in these courts are divines, as archbishops, bishops, archdeacons, &c.

COURT *of common pleas*. See COMMON PLEAS.

COURT *of delegates*, is the highest court for civil affairs that concern the church. See DELEGATES.

COURTS, *ecclesiastical*, are those courts which are held by the king's authority, as supreme governor of the church, for matters which chiefly concern religion. As to suits in spiritual or ecclesiastical courts, they are for the reformation of manners; as for punishing of heresy, defamation, laying violent hands on a clerk, and the like; and some of their suits are to recover something demanded, as tithes, a legacy, contract of marriage, &c.; and in cases of this nature, the court may give costs, but not damages. The proceedings in the ecclesiastical courts are according to the civil and canon law. they are not courts of record.

COURT *of exchequer*. See EXCHEQUER.

COURT *of hustings*, the highest court of record holden at Guildhall, for the city of London, before the lord mayor and aldermen, the sheriffs, and recorder. 4 Inst. 247. This court determines all pleas, real and mixed; and here all lands, tenements, and hereditaments, rents, and services, within the city of London and suburbs of the same, are pleable in two hustings; one called hustings of the plea of lands, and the other hustings of the common pleas. In the hustings of plea of lands are brought writs of right patent, directed to the sheriffs of London. In the hustings of common pleas are pleaded writs ex gravi querela, writs of gravelet, of dower, waste, &c. If an erroneous judgment be given in the hustings, the party grieved may sue a commission out of chancery, directed to certain persons, to examine the record, and thereupon do right.

COURT *of king's bench*. See KING'S BENCH.

COURT *of the legate*, was a court obtained by cardinal Wolsey of pope Leo X. 9 Hen. VIII. wherein he had power to prove wills, and dispense with offences against the spiritual laws, &c. This court was, however, of short continuance.

COURT *of marshalsea*. See MARSHALSEA.

Court *martial*, is a court for punishing the offences of officers and soldiers in time of war. See 22, 29, and 32 Geo. II. c. 3, 6, 25, and 34.

Court *of nisi prius*. See Nisi Prius.

Court *of peculiars*, a spiritual court, held in such parishes as are exempt from the jurisdiction of the bishops, and are peculiarly belonging to the archbishop of Canterbury, in whose province there are 57 such peculiars.

Court *of piepowder*, a court held in fairs to do justice to buyers and sellers, and for redress of disorders committed in them; so called because they are most usual in summer, when the suitors to the court have dusty feet; and from the expedition in hearing causes proper thereunto, before the dust goes off the feet of the plaintiff and defendant. The court of piepowder may hold plea of a sum above 40*s*. The steward before whom the court is held is the judge, and the trial is by merchants and traders in the fair; and the judgment against the defendant shall be, quod amercietur. If the steward proceeds contrary to the statute 17 Edw. IV. he shall forfeit 5*l*.

Court *of requests*, was a court of equity, of the same nature with the court of chancery, but inferior to it. This court having assumed great power to itself, so that it became burthensome, Mich. anno 40 and 41 Eliz. in the court of common pleas, it was upon solemn argument adjudged, that the court of requests was no court of judicature, &c.; and by the statute 16 and 17 Char. I. c. 10, it was taken away. 4 Inst. 97.

By 41 Geo. III. c. 14, for extending the powers of the court of requests within the city of London, all debts amounting to less than 5*l*. due from any person within the jurisdiction of the city, are to be exclusively sued for and recovered. Two aldermen, and not less than twenty inhabitants, householders of the several wards and districts, are appointed commissioners and sit in rotation. The process is by summons; and the commissioners have power to award payment by such instalments as are consistent with the circumstances and ability of the debtor. In this court an attorney's privilege is of no avail.

Court *of the lord steward of the king's household*. The lord steward, or, in his absence, the treasurer and comptroller of the king's house, and steward of the marshalsea, may inquire of, hear and determine, in this court, all treasons, murders, manslaughters, bloodsheds, and other malicious strikings, whereby blood shall be shed, in any of the palaces and houses of the king, or in any other house wherein his royal person shall abide.

Courts *of universities*. These courts are called the chancellor's courts, and are kept by the vice-chancellors of Oxford and Cambridge. Their jurisdiction extends to all causes ecclesiastical and civil (except for maihem, felony, and relating to freehold) where a scholar, servant, or minister of the universities, is one of the parties to the suit. They proceed in a summary way, according to the practice of the civil law; and the judges in their sentences follow the justice and equity of the civil law, or the laws, statutes, and customs of the universities, or the laws of the land, at their discretion. If any erroneous judgment be given in these courts, appeal lies to the congregation; thence to the convocation; and thence to the king in chancery by his delegates.

Courts *of Wales*. By 34 and 35 Hen. VIII. c. 26, it is enacted, that there shall be a court of great session kept twice in every year in each of the twelve counties of Wales; and the justices of those courts may hold pleas of the crown in as large a manner as the king's bench, &c.; and also pleas of assize, and all other pleas and actions real and personal, in as large a manner as the common pleas, &c.

Writs of error shall lie from judgments in this great session, it being a court of record to the court of king's bench at Westminster. But the ordinary original writs of process from the king's courts at Westminster do not run into the principality of Wales, though process of execution does, as do also prerogative writs.

COURTESY, or Courtesy *of England*, a certain tenure whereby a man marrying an heiress seized of lands of fee simple or fee tail general, or seized as heir of the tail special, and having a child by her that comes alive into the world, though both it and his wife die forthwith, yet if she was in possession, he shall keep the land during his life, and is called *tenant per legem Angliæ*, or tenant by the courtesy of England; because this privilege is not allowed in any country except Scotland, where it is called *curialitas Scotiæ*.

COUSU, in heraldry, signifies a piece of another colour or metal placed on the ordinary, as if it were sewed on, as the word imports.

COVERT, in heraldry, denotes something like a piece of hanging, or a pavilion, falling over the top of a chief or other ordinary, so as not to hide but only to be a covering to it.

COWARD, in heraldry, a term given to a lion borne in an escutcheon with his tail doubled or turned in between his legs.

COWL, or Coul, a habit worn by the Bernardins and Benedictines, of which there are two kinds: one white, very large, worn in ceremonies; the other black, worn on ordinary occasions in the streets, &c.

CRAB, in zoology. See Cancer.

Crab's-claws. See Materia Medica.

Crab's-eyes. See Materia Medica.

Crab, or gin, an engine used for mounting large guns on their carriages, &c. It is composed of three long and stout legs, meeting together at their tops; these legs are round poles of about 12 or 13 feet long, whose diameters at the lower end are about four inches, five just below the roller besides the cheeks that are added to them in that place, and about three inches and a half above.

Two of these poles can be fixed at a certain distance from each other, by means of two iron bars placed horizontally, one being about four feet long, the other about seven; and a roller is made to run upon pivots turning on, or in, these two poles: this roller is commonly seven inches and three-fourths in diameter, and six feet long. A portion of twenty inches is left square at each end, and holes made in each to receive the handspikes by which the men turn the roller: but the middle part is made cylindrical, to wind the cable upon. The transverse iron bars are fixed with one end to one of the poles

by means of a bolt, and with the other end to the other pole with a bolt and key; so as to be readily taken out, in order that when the gin is to be removed from place to place the poles may lie close together upon the carriage. There are two iron band and two iron bolts to fasten each cheek (for the pivots) to the poles, and iron plates round the poles where the iron bars are fixed. The poles are hooped at each end; and the upper ends have straps through which an iron bolt passes: this bolt keeps the upper ends together, as well as serves to support the iron to which the windlass is hooked. The windlass contains two brass pulleys, about which the cable goes, which is fixed to the dolphins of the gun or mortar with another windlass, containing two brass pulleys likewise. When this machine is used, the whole is laid flat on the ground, the lower end of the single pole extending the contrary way, in order to fasten the upper windlass when the cable has been turned round both: after this the upper end is raised gradually till the feet of the three poles (each of which has an iron prong) stand nearly at equal distances; in such a manner as the legs of a theodolite, or plain table, when set up for use in the practice of surveying.

CRADLE, in surgery, a case in which a broken leg is laid after being set.

Cradle, among shipwrights, a timber frame made along the outside of a ship, for the convenience of launching her with ease and safety. See Plate XXXIX. Miscel. fig. 22.

CRAFT, in the sea-language, signifies all manner of nets, lines, hooks, &c. used in fishing. Hence all such little vessels as ketches, boys, and smacks, &c. used in the fishing trade, are called small craft.

CRAMBE, Sea-cabbage, Sea-beach Kale, or Sea-colewort, a genus of the siliquosa order, in the tetradynamia class of plants; and in the natural method anking under the 39th order, siliquosæ. The four longer filaments are forked at top, with an anthera only on one point of each; the fruit is a dry, globose, and deciduous berry. There are six species, three of them herbaceous esculents with perennial roots, producing annually large leaves resembling those of cabbage spreading on the ground, with strong flower-stalks and yellowish flowers. Only one of the species is a native of Britain. It grows wild on the shores of many of the maritime counties of England, but is cultivated in many gardens as a choice esculent; and the young robust shoots of its leaves and flower-stalks, as they issue forth from the earth after the manner of asparagus-shoots, are then in the greatest perfection for use. At this period, if covered when they rise with a garden-pot, they appear white as if blanched, and when boiled eat exceedingly sweet and tender. Its principal season for use is in April and May. This plant may also be employed in the pleasure-ground as a flowering perennial, for the stalks divide into fine branchy heads of flowers. It is propagated by seeds sown in any common light earth in autumn or spring, where the plants are to remain, which, when two years old, will produce shoots fit for use, will multiply exceedingly by the roots, and continue for many years. The crambe fruticosa is a greenhouse plant.

CRAMP, in medicine, a convulsive contraction of a muscular part of the body. It affects all parts indifferently; but the hams, calves, feet, and toes, oftener than the arms and hands.

Cramp-iron, or Cramps, a piece of iron bent at each end, which serves to fasten together pieces of wood, stones, or other things.

CRAMPONE'E, in heraldry, an epithet given to a cross which has at each end a cramp or square piece coming from it; that from the arm in chief towards the sinister angle, that from the arm on that side downwards, that from the arm in base towards the dexter side, and that from the dexter arm upwards.

CRANE. See Grus.

Crane, a machine used in building, on wharfs, and in warehouses, for raising and lowering huge stones, ponderous weights, packages, &c.

Cranes, until of late years, were commonly constructed as follows: The principal member is a strong upright beam or arbor, firmly fixed in the ground, and sustained by eight arms, coming from the extremities of four pieces of wood laid across, through the middle of which passes the foot of the beam. About the middle of the arbor the arms meet, and are mortised into it: its top ends in an iron pivot, on which is borne a transverse piece, advancing out to a good distance, something after the manner of a crane's neck, whence the machine has its name. This projecting piece is now more commonly called the jib or gibbet. The middle and extremities of this are again sustained by arms from the middle of the arbor: and over it comes a rope or cable, to one end of which the weight is fixed; the other is wound about the spindle of a wheel, which when turned (commonly by means of men walking upon the inside of the rim of the wheel) draws the rope, and that heaves up the weight; which may afterwards be applied to any side or quarter by the mobility of the transverse piece on the pivot. These cranes have usually been made of two kinds: in the first, called the rat-tailed crane, the whole machine with the load turns upon a strong axis: in the second kind the gibbet alone moves on its axis. But in either kind, if the machinery is put into motion by men walking within the wheel, as has been till lately the almost universal practice in this country, the labourers employed are exposed to extreme danger, and have frequently met with the most shocking and fatal accidents. It is not then to be wondered at, that skilful machanists should at length have devised cranes that are not only more safe, but more powerful in their operation, than the common walking crane.

The late Mr. Ferguson invented a crane which has three trundles, with different numbers of staves, that may be applied to the cogs of a horizontal wheel with an upright axle; round which is coiled the rope that draws up the weight. This wheel has 96 cogs; the largest trundle 24 staves, the next 12, and the smallest 6; so that the largest revolves four times for one revolution of the wheel, the next 8, and the smallest 16. A winch is occasionally fixed on the axis of either of these trundles for turning it; and is applied to the one or the other according as the weight to be raised is smaller or larger. While this is drawing up, the ratch-teeth of a wheel slip round below a catch that falls into them, prevents the crane from turning backwards, and detains the weight in any part of its ascent, if the man who works

at the winch should accidentally quit his hold, or wish to rest himself before the weight is completely raised. Making a due allowance for friction, a man may raise by such a crane, from three times to twelve times as much in weight as would balance his effort at the winch, viz. from 90 to 360lbs. taking the average labour.

But several cranes which are preferable to the common walking-crane, while they are free from the dangers attending that machine, lose at the same time one of its advantages; that is, they do not avail themselves of that addition to the moving power which the weight of the men who are employed may furnish. Yet this advantage has been long since ensured by the mechanists on the continent, who cause the labourers to walk upon an inclined plane, turning upon an axis. The same principle has been lately brought into notice, probably without ever knowing it had been adopted before, by Mr. James White, of Chevening, in Kent: his crane is exhibited in fig. 1. as it was described in the Transactions of the Society for the Encouragement of the Arts. See Plate XXXVII. Cranes.

A (fig. 1.) is a circular inclined plane, moving on a pivot underneath, and carrying round with it the axis E. A person walking on this plane, and pressing against the lever B, throws off the gripe D, by means of an iron rod C; and thus admits the plane and its axis to move freely, and raise the weight G by the coiling of the rope F round the axis E.

To show more clearly the construction and action of the lever and gripe, a plan of the circular inclined plane, with the level and gripe, is added, (see fig. 2.) where B represents the level, D the spring or gripe. In this plan, where the level B is in the situation in which it now appears, the spring or gripe D presses against the periphery of the plane, as shown by the double line, and the machine cannot move; but when the lever B is pressed out to the line H, the gripe is also thrown off to the line I, and the whole machine left at liberty to move. One end of a rope or cord, of a proper length, is fixed near the end of the lever B, and the other end made fast to one of the uprights, serving to prevent the lever moving too far when pressed by the man.

The supposed proprietors of this crane, for which the premium of 40 guineas was adjudged by the society to the inventor, are as follows:

1. It is simple, consisting merely of a wheel and axile. 2. It has comparatively little friction, as is obvious from the bare inspection of the figure. 3. It is durable, as is evident from the two properties above-mentioned. 4. It is safe; for it cannot move but during the pleasure of a man, and while he is actually pressing on the gripe-lever. 5. This crane admits of an almost infinite variety of different powers, and this variation is obtained without the least alteration of any part of the machine. If, in unloading a vessel, there should be found goods of any weight; from a few hundreds to a ton and upwards, the man that does the work will be able so to adapt his strength to each as to raise it in a space of time proportionate to its weight; he walking always with the same velocity as nature and his greatest ease may teach him.

It is a great disadvantage in some cranes, that they take as long time to raise the smallest as the largest weight, unless the man who works them turns or walks with such velocity as must soon tire him. In other cranes, perhaps two or three different powers may be procured; to obtain which, some pinion must be shifted, or fresh handle applied or resorted to. In this crane, on the contrary, if the labourer finds his load so heavy as to permit him to ascend the wheel without its turning, let him only move a step or two towards the circumference, and he will be fully equal to the task. Again, if the load is so light as scarcely to resist the action of his feet, and thus to oblige him to run through so much space as to tire him beyond necessity, let him move laterally towards the centre, and he will soon feel the place where his strength will suffer the least fatigue by raising the load in question. One man's weight applied to the extremity of the wheel would raise upwards of a ton; and it need not be added, that a single-sheaved block would double that power. Suffice it to say, that the size may be varied in any required ratio; and that this wheel will give as great advantage at any point of its plane as a common walking-wheel of equal diameter, as the inclination can be varied at pleasure, as far as expediency may require. It may be necessary to observe, that what in the figure is the frame, and seems to form a part of the crane, must be considered as a part of the house in which it is placed; since it would be mostly unnecessary should such cranes be erected in houses already built. With respect to the horizontal part, by walking on which the man who attends the jib occasionally assists in raising the load, it is not an essential part of this invention, where the crane is not immediately contiguous to the jib; although, where it is, it would certainly be very convenient and economical.

Notwithstanding, however, the advantages which have been enumerated, Mr. White's crane is subject to this objection, that it derives less use than might be wished from the weight of the man or men: for a great part of that weight (half of it, if the inclination be 30 degrees) lies directly upon the plane, and has no tendency to produce motion. Besides, when this crane is of small dimensions, the effective power of the men is very unequal, and the barrel too small for winding a thick rope: when large, the weight of the materials added to that of the men put it out of shape, and give it the appearance of a large unwieldy moving floor.

Fig. 3 represents a crane in common use, in situations where no building is wanted over it. A B is a strong upright shaft, working through a collar in the timber-floor of the wharf, and on a pivot in the bottom of a well, some feet below it. D E are the timbers forming the jib to support the pulley I over which the chain passes. G H I is a cast iron cross bolted to the framing at two of its extremities: another cross fixed in the same manner to the other side, makes a frame for the wheels K, L. M, N. K is a pinion with 15 teeth: the ends of its spindle Q pass through the cross, and are squared for winch handles by which it turned. This works into the wheel L of 22 teeth, its spindle P, and has also square ends for the winches. It has a pinion N of 7 teeth upon it, which works the wheel M of 100 teeth, fixed to the roll on which the chain winds, whose spindle is Q. This crane has the advantage of traversing a whole circle, which for many purposes is very useful. It has several different powers by men working at winches put on the

different spindles separately or combined. When the man works by the spindle P, the pinion K is thrown out of gear by sliding its spindle along, and when he works by the spindle Q, the wheels K and L are thrown out. This is prevented from happening accidentally by a collar on each spindle acting against a double clep R, fig. 4. moving on a centre at S, and is made to act by the weight T: when this weight is lifted up, both spindles are at liberty to be slid along. In figure 5, is shown the method, in common use, of slinging a large block of stone, by which the necessity of passing the chain under it is avoided.

Fig. 6 is a simple and effective crane at a wharf on the banks of the Thames, between Greenwich and Woolwich. ABC are three upright posts connected at the top by a triangular frame, across the middle of which is a beam D, between this and a block on the ground the jib plays: on each side of the upright shaft E, two bars FG are bolted, spreading out as they recede from it to receive the wheel H; I I are braces to support the bars. At that part where the braces are bolted to the upright, an horizontal frame K is fixed for carrying the roll and winch: the rope which winds round this goes over the pully L, and round the large wheel H. The rope which lifts the goods winds on each end of the axle of this wheel; and the middle of it passes through a pully-block O, to which the goods are hooked.

Fig. 7 is a crane used at several of the wharfs belonging to the Grand-junction canal company at Paddington: the frame of it is the same as fig. 6. A is the main shaft. BB are the horizontal bars of greater length than usual, bolted to the shaft A, near the middles, and having two struts (EE and FF) at each end, which makes this kind of jib very strong. The wheel G is placed at the short end of the jib; and the rope which winds round its axis, passes over pulleys H at the other end.

Crane-lines, in a ship, are lines going from the upper end of the spritsail-topmast to the middle of the forestays. They serve to keep the spritsail-topmast upright and steady in its place, and to strengthen it.

CRANICHIS, a genus of the class and order gynandria decandria. The essential character is, nectary galeated. There are five species.

CRANIOLARIA, a genus of the angio-spermia order, in the didynamia class of plants; and in the natural method ranking under the 40th order, personatæ. The calyx of the flower is double, the under one tetraphyllous, the upper one a monophyllous spatha; the tube of the corolla very long; the capsule almost the same with that of the martynia. There is one species, a native of New Spain, not possessed of any remarkable property.

CRANK, a contrivance in machines, in manner of an elbow, only of a square form, projecting from a spindle, and serving by its rotation to raise and fall the pistons of engines.

Crank likewise denotes the iron support for a lantern, and also the iron, made fast to a stock of a bell for ringing it. In the sea-language, a ship is said to be crank-sided when she can bear but small sail, for fear of oversetting: and when a ship cannot be brought on the ground without danger, she is said to be crank by the ground.

CRANZIA, a genus of the pentandria monogynia class and order. The calyx is five-parted, petals five; nec. none: berry or berried caps. There is one species, a native of the East Indies.

CRAPE, a light transparent stuff, in manner of gauze: made of raw silk gummed and twisted on the mill, woven without crossing, and much used in mourning. Crapes are either craped (*i. e.* crisped), or smooth; the first double, expressing a closer mourning; the latter single, used for that less deep. The white is reserved for young people. The silk destined for the first is more twisted than that for the second; it being the greater or less degree of twisting, especially of the warp, which produces the crisping given it when taken out of the loom, steeped in clear water, and rubbed with a piece of wax for the purpose. Crapes are all dyed raw. The invention of this stuff came originally from Bologna; but, till of late years, Lyons is said to have had the chief manufacture of it.

CRASPEDIA, a genus of the class and order syngenesia polygamia. The calyx is imbricate. Florets in depressed bundles, down feathered, recept. chaffy. There is one species, a native of New Zealand.

CRASSULA, lesser orpine, or live-ever; a genus of the pentagynia order, in the pentandria class of plants; and in the natural method ranking under the 13th order, succulentæ. The calyx is pentaphyllous; the petals five, with five nectariferous scales at the base of the germen, and five capsules. There are 64 species, all of them natives of warm climates. Several of them are cultivated in this country, but require the assistance of artificial heat for their preservation. They rise from one foot to six or eight in height, and are ornamented with oblong, thick, succulent leaves, and funnel-shaped pentapetalous flowers of a scarlet, white, or greenish colour. They are propagated by offsets or cuttings; and must be potted in light sandy compost, retained in a sunny part of the greenhouse all winter, and very sparingly watered. In summer they may be placed in the full air in a sheltered place, and in dry weather watered twice a week.

CRATÆGUS, wild service-tree, hawthorn, &c. a genus of the digynia order, in the icosandria class of plants; and in the natural method ranking under the 36th order, pomaceæ. The calyx is quinquefid; the petals five; the berry inferior, dispermous. There are 23 species, all of the tree and shrub kind, hardy, and deciduous. Those most valuable for economical and ornamental purposes in gardening are the following;

1. The oxycantha, bawthorn, or white thorn, grows naturally all over Europe. In the state in which we are used to observe it, it is nothing better than a tall, uncouth, irregular shrub; but trained up as a standard, it swells to a large timber size, with a tall stem and a full spreading head. The standard-hawthorn, whether we view its flowers in the spring, its foliage in the summer, or its fruit in the autumn or winter, is one of the most ornamental plants, standing singly, that can be scattered over a park or lawn.

The common hawthorn sports in the following varieties: the large scarlet hawthorn; the yellow hawthorn; the white hawthorn; the maple-leaved hawthorn; the double-blossomed hawthorn; the Glastonbury thorn. The last of these differs in no respect from the common hawthorn, only that it sometimes flowers in the winter. It is said to have originally been the staff of Joseph of Arimathea, who, attended by eleven companions, came over into

Britain, and founded, in honour of the Blessed Virgin, the first Christian church in this isle. As a proof of his mission, he is said to have stuck his staff into the ground, which immediately shot forth and bloomed. This tree is falsely said to have blossomed on Christmas-day ever since, and is universally distinguished by the name of the Glastonbury thorn.

2. The azarolus, or parsley-leaved thorn, is a native of Italy and the south of France. It will grow to be fifteen or sixteen feet high. The leaves are large, nearly trifid, serrated, and obtuse. The flowers are large, come out in May, and in the different varieties are succeeded by fruit of different size, shape, and relish. The principal varieties of this species are: the azarole with strong thorns; the azarole with no thorns; the jagged-leaved azarole; the oriental medlar.

3. The aria, called the white-beam tree, is a native of most of the cold countries of Europe. It will grow to be more than twenty feet high. This tree is engaging at all times of the year, and catches the attention even in the winter; for then we see it stand, though naked of leaves, with a straight stem, with smooth branches spotted with white, at the end of which are the buds, swelled for the next year's shoot, giving the tree a bold and fine appearance. In the spring the leaves come out, of course, and look delightfully, having their upper surface green and the lower white. Their figure is oval; they are unequally serrated, about three inches long, and half as wide. Several strong nerves run from the mid-rib to the border, and they are placed alternately on the branches, which appear as if powdered with the finest meal. The flowers are produced at the end of the branches in May: they are white; grow in large bunches, having mealy footstalks; and are succeeded by red berries, which will be ripe in autumn.

4. The terminalis, wild service, or maple-leaved service, is a large growing tree, native of England, Germany, Switzerland, and Burgundy. It will arrive at near fifty feet, and is worth propagating for the sake of the timber, which is very white and hard. This tree grows naturally in several woods in England; and it is the fruit of this species that is tied in bunches and exposed for sale in the autumn: it is gathered in the woods, and by some persons is much liked. The leaves in some degree resemble those of the maple-tree in shape; their upper surface is a fine green, their under hoary; and they grow alternately on the branches. The flowers come out in May, exhibiting themselves in large clusters at the end of the branches. They are white, and are succeeded by the fruit, which, when ripe, is of a brown colour, and about the size of a large haw.

5. The coccinea, or great American hawthorn, is a native of Virginia and Canada. It will grow to be near twenty feet high. The stem is robust, and covered with a light-coloured bark. The branches are produced without order, are of a dark-brown colour, and possessed of a few long sharp thorns. The leaves are spear-shaped, oval, smooth, and serrated; of a thickish consistence, and often remain on the tree the greatest part of the winter. Each separate flower is large; but as few of them grow together, the umbels they form are rather small. They come out in May, and are succeeded by a large dark-red coloured fruit, which ripens late in the autumn. The varieties of this species are: the pear-leaved thorn; the plum-leaved thorn with very long strong spines and large fruit; the plum-leaved thorn with short spines and small fruit.

6. The crus galli, or cockspur-thorn, is a native of Virginia and Canada, and grows to about twenty feet high. It rises with an upright stem, irregularly sending forth branches, which are smooth, and of a brownish colour, spotted thinly with small white spots. It is armed with thorns that resemble the spurs of cocks, which gained it the appellation of cockspur-thorn. In winter the leaf-buds appear large, turgid, and have a bold and pleasant look among others of different appearances. In summer this tree is very delightful. The leaves are oval, angular, serrated, smooth, and bend backwards. They are about four inches long, and three and a half broad; have five or six pair of strong nerves running from the mid-rib to the border; and dye to a brownish-red colour in the autumn. The flowers are produced in very large umbels, making a noble show in May; and are succeeded by large fruit of a bright red colour, which have a good effect in the winter. The principal varieties of this species are: the cockspur hawthorn with many thorns; the cockspur hawthorn with no thorns; the cockspur hawthorn with eatable fruit.

7. The tomentosa, woolly-leaved hawthorn, grows to about seven or eight feet high. The branches are slender, and closely set with sharp thorns. The leaves are cuneiform, oval, serrated, and hairy underneath. The flowers are small, and of a white colour: they are produced from the sides of the branches about the end of May; and are succeeded by yellow fruit, which ripens late in autumn. There is a variety of this called the Carolina hawthorn, which has longer and whiter leaves, large flowers and fruit, and no thorns.

8. The viridis, or green-leaved Virginia hawthorn, has the stem and branches together destitute of thorns. The leaves are lanceolate, oval, nearly trilobate, serrated, smooth, and green on both sides. The flowers are white, moderately large, come out the end of May, and are succeeded by a roundish fruit, which will be ripe late in the autumn.

The respective species are all propagated by sowing the seeds; and the varieties are continued by budding them upon stocks of the white thorn. This latter method is generally practised for all the sorts; though, when good seeds can be procured, the largest and most beautiful plants are raised that way.

CRATER, in astronomy, a constellation of the southern hemisphere, consisting of seven stars according to Ptolemy's catalogue, of eight in Tycho's, and eleven in the Britannic catalogue.

CRATEVA, the garlic pear; a genus of the monogynia order, in the dodecandria class of plants; and in the natural method ranking under the 25th order, putamineæ. The corolla is tetrapetalous; the calyx quadrifid; the berry inferior, dispermous. There are five species, natives of both Indies. They are of the tree kind; and are chiefly distinguished by their fruit. The tapia, or garlic pear, has a smooth round fruit about the size of an orange, with a hard brown shell or cover, which inclose a mealy pulp, filled with kidney-shaped seeds. It has a strong smell of garlic, and communicates the same to such animals as feed upon it. The tender buds from the young

branches being bruised and applied to the naked skin, will blister as effectually as cantharides. It rises to the height of about thirty feet. The marmelos grows to the size of a very large tree, with trifoliate leaves. The flowers have the smell of roses, and are succeeded by an oblong fruit of the size of an apple, covered with a very hard bony shell, and containing a soft fleshy pulp, having the taste of quinces. From the flowers of this plant is obtained by distillation a water highly odoriferous and cordial; and the pulpy part of the fruit is prepared into various kinds of marmalades. Both species may be propagated in this country by seeds.

CRAX, in ornithology, the curassou, a genus of birds belonging to the order of gallinæ. The base of the beak of each mandible is covered with wax; and the feathers of the head are curled. There are five species, viz. 1. the alecator, or India hen of Sloane, is about the size of a small turkey. It is black, with a white belly. A yellow wax covers about half of each mandible; the tongue is entire; the temples are bare and black; the tail is roundish, and consists of 14 prime feathers; the legs are strong, and of a dusky brown colour. They are frequent at Guiana; and are called powese by the natives from their cry, which is somewhat similar; are pretty numerous in the woods; and make no small part of the food of the planters, who are supplied with them by the Indian hunters; and their flesh is reckoned delicate, much like that of a turkey. They are easily brought up tame, and are frequently found in the Dutch settlements of Berbice, Essequibo, and Demerara. They are called at Brasil by the name of curasso. 2. The rubra, or Peruvian hen, is red, with a blueish head. These birds are natives of Mexico and Peru. They feed on fruits, and perch at night on trees: the flesh is white, and esteemed very good food. They are frequently kept tame in the menageries in England, and readily mix with other poultry, feeding on bread and grain; but this climate is not warm enough for their nature, they not being able to bear the dampness of the grass of our meadows, which renders them subject to have their toes rot off. They will often live in this state some time; and in one instance which Mr. Latham saw, the whole of one foot was gone, and but part of one toe left on the other, before the creature died. 3. The mitu, or Brazilian pheasant, is black, with a dusky belly, and red wax: it is a native of Guinea and Brazil. 4. The globicera, has a yellow protuberance between the nostrils, and is of a blueish-black colour: it is likewise a native of Brazil. 5. The pauxi, or Mexican pheasant of Brisson, is of a blueish colour, with blue wax, and the tip of the tail and belly white: is a native of Mexico. See Pl. XL. Nat. Hist. figs. 148, 149.

CRAY-FISH, or CRAW-FISH. See CANCER.

CRAYON, a name for all coloured stones, earths, or other minerals, used in designing or painting in pastel. Crayons may be made of any colour, and adapted for the faces of men, women, landscapes, clouds, sun-beams, buildings, and shadows, in the following manner. Take plaister of Paris, or alabaster calcined, and of the colour of which you intend to make your crayons, a sufficient quantity: grind them first asunder, and then together, and with a little water make them into paste: then roll them with your hand upon the grinding-stone into long pieces, and let them dry moderately in the air; when they are to be used, scrape them to a point like a common pencil.

CRAYON-PAINTING. Whether the painter works with oil-colours, water-colours, or crayons, the grand object of his pursuit is still the same: a just imitation of nature. But each species has its peculiar rules and methods. Painting with crayons requires, in many respects, a treatment different from painting in oil-colours: because all colours used dry are in their nature of a much warmer complexion than when wet with oils, &c. For this reason, in order to produce a picture, a much greater portion of what painters term cooling tints must be applied in crayon-painting, than it would be judicious to use in oils. Without any danger of a mistake, it is to be supposed, the not being acquainted with this observation is one great cause why so many oil-painters have no better success when they attempt crayon-painting. On the contrary, crayon-painters being so much used to those tints which are of a cold nature when used wet, are apt to introduce them too much when they paint with oils, which is seldom productive of a good effect.

We shall now endeavour to give the student some directions towards the attainment of excellence in this art.

Of the application of the crayons, with some previous dispositions.—The student must provide himself with some strong blue paper, the thicker the better, if the grain is not too coarse or knotty, though it is almost impossible to get any entirely free from knots. The knots should be levelled with a penknife or razor, otherwise they will prove exceeding troublesome. After this is done the paper must be pasted very smooth on a linen cloth, previously strained on a deal frame, the size according to the artist's pleasure: on this the picture is to be executed; but it is most eligible not to paste the paper on till the whole subject is first dead-coloured. The method of doing this is very easy, by laying the paper with the dead-colour on its face, upon a smooth board or table, when, by means of a brush, the back side of the paper must be covered with paste; the frame with the strained cloth must then be laid on the pasted side of the paper; after which turn the painted side uppermost, and lay a piece of clean paper upon it, to prevent smearing it: this being done, it may be stroked gently over with the hand; by which means all the air between the cloth and the paper will be forced out.

When the paste is perfectly dry, the student may proceed with the painting. The advantages arising from pasting the paper on the frame according to this method, after the picture is begun, are very great, as the crayons will adhere much better than any other way; which will enable the student to finish the picture with a firmer body of colour, and greater lustre.

When the painters want to make a very correct copy of a picture, they generally make use of tiffany or black gauze, strained tight on a frame; which they lay flat on the subject to be imitated, and with a piece of sketching chalk trace all the outlines on the tiffany. They then lay the canvas to be painted on flat upon the floor, placing the tiffany with the chalked lines upon it, and with an handkerchief brush the whole over: this presents the exact outlines of the picture on the canvas. The crayon-painter may also make use of this method when the subject of his imitation is in oils; but in copying a

crayon-picture he must have recourse to the following method, on account of the glass:

The picture being placed upon the easel, let the outlines be drawn on the glass with a small camel's-hair pencil dipped in lake, ground thin with oils, which must be done with great exactness. After this is accomplished, take a sheet of paper of the same size and place it on the glass, stroking over all the lines with the hand, by which means the colour will adhere to the paper, which must be pierced with pin-holes pretty close to each other. The paper intended to be used for the painting must next be laid upon a table, and the pierced paper placed upon it; then with some fine pounded charcoal, tied up in a piece of lawn, rub over the pierced lines, which will give an exact outline; but great care must be taken not to brush this off till the whole is drawn over with sketching chalk; which is a composition made of whiting and tobacco-pipe clay, rolled like the crayons, and pointed at each end.

When a student paints immediately from the life, it will be most prudent to make a correct drawing of the outlines on another paper, the size of the picture he is going to paint, which he may trace by the preceding method, because erroneous strokes of the sketching chalk (which are not to be avoided without great expertness) will prevent the crayons from adhering to the paper, owing to a certain greasy quality in the composition.

The student will find the sitting posture, with the box of crayons on his lap, the most convenient method for him to paint. The part of the picture he is immediately painting should be rather below his face, for if it is placed too high the arm will be fatigued. Let the windows of the room where he paints be darkened, at least to the height of six feet from the ground; and the subject to be painted should be situated in such a manner that the light may fall with every advantage on the face, avoiding too much shadow, which seldom has a good effect in portrait-painting, especially if the face he paints from has any degree of delicacy.

Before he begins to paint let him be attentive to his subject, and appropriate the action or attitude proper to the age of the subject: if a child, let it be childish; if a young lady, express more vivacity than in the majestic beauty of a middle-aged woman, who also should not be expressed with the same gravity as a person far advanced in years. Let the embellishments of the picture, and introduction of birds, animals, &c. be regulated by the rules of propriety and consistency.

The features of the face being correctly drawn with chalks, let the student take a crayon of pure carmine, and carefully draw the nostril and edge of the nose next the shadow; then, with the faintest carmine tint, lay in the highest light upon the nose and forehead, which must be executed broad. He is then to proceed gradually with the second tint, and the succeeding ones, till he arrives at the shadows, which must be covered brilliant, enriched with much lake, carmine, and deep green. This method will at first offensively strike the eye, from its crude appearance; but in the finishing it will be a good foundation to produce a pleasing effect, colours being much more easily sullied when too bright, than, when the first colouring is dull, to raise the picture into a brilliant state. The several pearly tints discernible in fine complexions must be imitated with blue verditer and white, which answers to the ultramarine tints used in oils. But if the parts of the face where these tints appear are in shadow, the crayons composed of black and white must be substituted in their places.

Though all the face when first coloured should be laid in as brilliant as possible, yet each part should be kept in its proper tone; by which means the rotundity of the face will be preserved.

Let the student be careful when he begins the eyes, to draw them with a crayon inclined to the carmine tint, of whatever colour the irises are of; he must lay them in brilliant, and at first not loaded with colour, but executed lightly: no notice is to be taken of the pupil yet. The student must let the light of the eye incline very much to the blue cast, cautiously avoiding a staring white appearance (which when once introduced is seldom overcome), preserving a broad shadow thrown on its upper part by the eyelash. A black and very heavy tint is also to be avoided in the eyebrows; it is therefore best to execute them like a broad glowing shadow at first, on which, in the finishing, the hairs of the brow are to be painted; by which method of proceeding the former tints will show themselves through, and produce the most pleasing effect.

The student should begin the lips with pure carmine and lake, and in the shadow use some carmine and black; the strong vermilion tints should be laid on afterwards. He must beware of executing them with stiff harsh lines, gently intermixing each with the neighbouring colours, making the shadow beneath broad, and enriched with brilliant crayons. He must form the corner of the mouth with carmine, brown ochre, and greens, variously intermixed. If the hair is dark, he should preserve much of the lake and deep carmine tints therein; this may easily be overpowered by the warmer hair tints, which, as observed in painting the eyebrows, will produce a rich effect when the picture is finished; on the contrary, if this method is unknown or neglected, a poverty of colouring will be discernible.

When the head is brought to some degree of forwardness, let the back-ground be laid in, which must be treated in a different manner, covering it as thin as possible, and rubbing it into the paper with a leather stump. Near the face the paper should be almost free from colour, for this will do great service to the head, and by its thinness give both a soft and solid appearance. In the back-ground also no crayon that has whiting in its composition should be used, but chiefly such as are the most brilliant and the least adulterated. The ground being painted thin next the hair, will give the student an opportunity of painting the edges of the hair over in a light and free manner when he gives the finishing touches.

The student having proceeded thus far, the face, hair, and back-ground, being entirely covered, he must carefully view the whole at some distance, remarking in what respect it is out of keeping, that is, what parts are too light and what too dark; being particularly attentive to the white or chalky appearances, which must be subdued with lake and carmine. The above method being properly put into execution, will produce the appearance of a painting principally composed of three colours,

viz. carmine, black, and white, which is the best preparation a painter can make for producing a fine crayon picture.

The next step is to complete the back-ground and the hair, as the dust, in painting these, will fall on the face, and would much injure it if that was completed first. From thence proceed to the forehead, finishing downward till the whole picture is completed.

In painting over the forehead the last time, begin the highest light with the most faint vermilion tint, in the same place where the faint carmine was first laid, keeping it broad in the same manner. In the next shade succeeding the lightest, the student must work in some light-blue tints, composed of verditer and white, intermixing with them some of the deeper vermilion tints, sweetening them together with great caution, insensibly melting them into one another, increasing the proportion of each colour as his judgment shall direct. Some brilliant yellows may also be used, but sparingly; and towards the roots of the hair strong verditer tints, intermixed with green, will be of singular service. Cooling crayons, composed of black and white, should succeed these, and melt into the hair. Beneath the eyes the sweet pearly tints are to be preserved, composed of verditer and white; and under the nose and on the temples the same may be used; beneath the lips tints of this kind also are proper, mixing them with the light greens and some vermilion.

In finishing the cheeks let the pure lake clear them from any dust contracted from the other crayons; then with the lake may be intermixed the bright vermilion; and last of all (if the subject should require it), a few touches of the orange-coloured crayon, but with extreme caution; after, sweeten that part with the finger as little as possible, for fear of producing a heavy disagreeable effect on the cheeks; as the beauty of a crayon-picture consists in one colour showing itself through, or rather between, another; this the student cannot too often remark, it being the only method of imitating beautiful complexions.

The eye is the most difficult feature to execute in crayons, as every part must be expressed with the utmost nicety to appear finished; at the same time that the painter must preserve its breadth and solidity while he is particularizing the parts. To accomplish this, it will be a good general rule for the student to use his crayon in sweetening as much, and his finger as little, as possible. When he wants a point to touch a small part with, he may break off a little of his crayon against the box, which will produce a corner fit to work with in the minutest parts. If the eyelashes are dark, he must use some of the carmine and brown ochre, and the crayon of carmine and black; and with these he may also touch the iris of the eye (if brown or hazel), making a broad shadow, caused by the eyelash. Red tints of vermilion, carmine, and lake, will execute the corners of the eye properly; but if the eyelids are too red, they will have a disagreeable sore appearance. The pupil of the eye must be made of pure lamp-black: between this and the lower part of the iris the light will catch very strong, but it must not be made too sudden, but be gently diffused round the pupil till it is lost in shade. When the eyeballs are sufficiently prepared, the shining spect must be made with a pure white crayon, which should be first broken to a point, and then laid on firm; but as it is possible they may be defective in neatness, they should be corrected with a pin, taking off the redundant parts, by which means they may be formed as neat as can be required.

The difficulty with respect to the nose, is to preserve the lines properly determined; and at the same time so artfully blended into the cheek, as to express its projection, and yet no real line to be preceptible upon a close examination; in some circumstances it should be quite blended with the cheek, which appears behind it, and determined entirely with a slight touch of red chalk. The shadow caused by the nose is generally the darkest in the whole face, partaking of no reflection from its surrounding parts. Carmine and brown ochre, carmine and black, and such brilliant crayons, will compose it best.

The student having before prepared the lips with the strongest lake and carmine, &c. must with these colours make them completely correct; and when finishing introduce the strong vermilions, but with great caution, as they are extremely predominant. This, if perfectly touched, will give the lips an appearance equal, if not superior, to those executed in oils, notwithstanding the seeming superiority the latter have by means of glazing, of which the former are entirely destitute.

When the student paints the neck, he should avoid expressing the muscles too strong in the stem, nor should the bones appear too evident on the chest, as both have an unpleasing effect, denoting a violent agitation of the body; a circumstance seldom necessary to express in portrait-painting. The most necessary part to be expressed, and which should ever be observed (even in the most delicate subjects,) is a strong marking just above the place where the collar-bones unite; and if the head is much thrown over the shoulders, some notice should be taken of the large muscle that rises from behind the ear, and is inserted into the pit between the collar bones. All inferior muscles should be, in general, quite avoided. The student will find this caution necessary, as most subjects, especially thin persons, have the muscles of the neck much more evident than it would be judicious to imitate. As few necks are too long, it may be necessary to give some addition to the stem, a fault on the other side being quite unpardonable, nothing being more ungraceful than a short neck. In colouring the neck, let the student preserve the stem of a pearly hue, and the light not so strong as on the chest. If any part of the breast appears, its transparency must also be expressed by pearly tints; but the upper part of the chest should be coloured with beautiful vermilions delicately blended with the other.

Of the drapery.—Dark blue, purple, black, pink, and all kinds of red draperies also, should be first tinged with carmine, which will render the colours much more brilliant than any other method; over this should be laid on the paper the middle tint (a medium between the light and dark tints, of which the drapery is to be painted), except the dark masses of shadow, which should be laid on at first as deep as possible: these, sweetened with the finger, being destitute of the smaller folds, will exhibit a masterly breadth which the lesser folds, when added, ought by no means to destroy. With the light and dark tints the smaller parts are next to be made with freedom,

executing as much with the crayon, and as little with the finger, as possible; in each fold touching the last stroke with the crayon, which stroke the finger must never touch. In the case of reflections, the simple touch of the crayon will be too harsh, therefore fingering will be necessary afterwards, as reflected lights are always more gentle than those which are direct. With respect to reflections in general, they must always partake of the same colour as the object reflecting; but in the case of single figures it may be useful to make some particular observations.

In a blue drapery, let the reflections be of a greenish cast; in green draperies, make them of a yellow tint; in yellow, of an orange; in orange, reflect a reddish cast; in all reds, something of their own nature, but inclined to a yellow: black should have the reddish reflection; the reflection of a reddish tint will also present purples to the best advantage.

Of whatever colour the drapery is, the reflection of the face must partake of it; otherwise the picture, like paintings on glass, will have but a gaudy effect.

Linen, lace, fur, &c. should be touched spiritedly with the crayon, fingering very little, except the latter; and the last touches even of this, like all other parts, should be executed by the crayon, without sweetening by the finger.

The methods above recommended have been practised by the most celebrated crayon-painters, whose works have been held in public estimation: but the knowledge of, and ability to execute, each separate part with brilliancy and truth, will be found very insufficient to constitute a complete painter, without his jndgment enables him to unite them with each other, by correctness of drawing, propriety of light and shadow, and harmony of colouring. In order to accomplish this, the student should carefully avoid finishing one part in particular, till he has properly considered the connection it is to have with the rest. The neglect of this is the principal reason why the performances of indifferent painters are so destitute of what is termed breadth; so conspicuously beautiful in the works of great masters. It must be granted that this observation relates more particularly to large compositions, where a diversity of figures requires such a judicious disposition, that each may assist in the combination of a kind of universal harmony; yet, even in portrait-painting, the student should be particularly attentive to observe this idea of breadth, if he is desirous of acquiring that importance and dignity which constitute excellence in painting.

CREAM of tartar, called also chrystals of tartar. See PHARMACY.

CREDITORS shall recover their debts of executors, or administrators, who in their own wrong, waste, or convert to their use, the estate of the deceased. 30 C. II. c. 7. Wills and devises of lands, &c. as to creditors on bonds, or other specialties, are declared void: and the creditors may have actions of debt against the heir at law and divisees, 3 and 4 W. and M. c. 14: and in favour of creditors, whenever it appears to be the testator's intent, in a will, that his land should be liable for paying his debts, in such case equity will make them subject, though there are no express words; but there must be more than a bare declaration, or it shall be intended out of the personal estate. 2 Vern. Rep. 708.

CREEPER. See CERTHIA.

CREEPER, at sea, a sort of grapnel, but without flooks, used for recovering things fallen overboard. See Pl. XXXIX. Miscel. fig. 23.

CRENATED. See BOTANY.

CRENCLES, in a ship, small ropes spliced into the bolt ropes of the sails at the main-mast and fore-mast. They are fastened to the bow-line bridles; and are also to hold by, when a bonnet is shaken off.

CRENELLE', or embattled, in heraldry, is used when any honourable ordinary is drawn like the battlements on a wall.

CRENOPHYLAX, in antiquity, a magistrate at Athens, who had the inspection of fountains.

CREPIS, bastard hawk-weed, a genus of the polygamia order, in the syngenesia class of plants, and in the natural method ranking under the forty-ninth order, compositæ. The receptacle is naked; the calyx calyculated, with deciduous scales; the pappus feathery and stalked. There are twenty species, most of them herbaceous annuals, rising to the height of a foot or a foot and a half, and having their branches terminated by ligulated compound red and yellow flowers. These are very large, and consist of many flat flowrets spread over one another imbricatim, and when fully blown appear as if radiated. They are very conspicuous and beautiful; and appear in June, July, and August. They are succeeded by plenty of seed, which if permitted to scatter on the ground, will produce a number of young plants without further trouble.

CREPITATION, that noise which some salts make over the fire in calcination, called also detonation.

CREPITATION is also used in surgery, for the noise made by the ends or pieces of bones, when the surgeon moves a limb to assure himself by his ear of the existence of a fracture.

CREPONDIA, in antiquity, a term used to express such things as were exposed along with children, as rings, jewels, &c. serving as tokens whereby they afterwards might be known.

CREPUSCULUM, in astronomy, twilight; the time from the first dawn or appearance of the morning to the rising of the sun; and again, between the setting of the sun and the last remains of day. The crepusculum is usually computed to begin and end when the sun is about eighteen degrees below the horizon; for then the stars of the sixth magnitude disappear in the morning, and appear in the evening. It is of longer duration in the solstices than in the equinoxes, and longer in an oblique than in a right sphere. The crepuscula are occasioned by the sun's rays refracted in our atmosphere.

CRESCENT, in heraldry, a bearing in form of a new moon.

CRESCENT is also an order of knights, instituted by Rennatus of Anjou, king of Sicily, about the year 1448; so called from the badge of this order, which was an enamelled crescent of gold.

CRESCENTIA, the calabash-tree; a genus of the angiospermia order, in the didynamia class of plants; and in the natural method ranking under the 25th order, putamineæ. The calyx is bipartite and equal; the corol-

la gibbous; the berry pedicellated or stalked, unilocular, and polyspermous; the seeds bilocular.

There are two species: 1. the cujete, with oblong narrow leaves and a large oval fruit, is a native of Jamaica and the Leeward islands. It has a thick trunk covered with a whitish bark, and rises from twenty to thirty feet high, and at the top divides into many branches, forming a large and regular head: the flowers are produced from the sides of the large branches, and sometimes from the trunk; standing upon long footstalks. They have but one petal, which is irregular; and are of a greenish-yellow colour, striped and spotted with brown. These are succeeded by very large fruit, generally spherical, sometimes oval; and at other times they have a contracted neck like a bottle; and are so large, that when the pulp and seeds are cleaned out, the shells will contain three pints or two quarts of liquid. The fruit is covered externally with a thin skin, of a greenish-yellow colour when ripe. When this is peeled off, there appears a hard ligneous shell, inclosing a pale-yellowish soft pulp of a tart unsavoury flavour, surrounding a great number of flat heart-shaped seeds. 2. The cucurbitina, or broad-leaved calabash, seldom rises more than 15 or 20 feet high, with an upright trunk, covered pith a white smooth bark, sending out many lateral branches at the top, with leaves three inches in length, and one and a quarter broad, ranged alternately. The flowers come out as in the former species; but are smaller, and of a deeper yellow colour. The fruit of this sort is sometimes round, sometimes oval, but of very unequal sizes. Both these species are easily propagated by seeds; but the plants are too tender to live in this country, unless they are constantly kept in a stove.

The shells of calabashes are made use of for various purposes. At Barbadoes, besides drinking-cups and punch-bowls, there are made of them spoons, dishes, and other utensils for the slaves. Some of these shells are so large, as to be capable of holding fifteen pints of water. The pulp is seldom eaten, except by cattle in the time of drought. The wood, which is hard and smooth, is made into stools, chairs, and other furniture.

CRESSA, a genus of the class and order pentandria digynia. The essential character is, calyx five-leaved: corolla, salver-form; filaments setting on the tube; capsules two-valved, one-seeded. There are 2 species.

CREST, in armoury, the top part of the armour, for the head, mounting over the helmet. It was for the most part made of feathers, or the hair of horses' tails or manes.

Crest, in heraldry, is the uppermost part of an armoury, or that part of the casque or helmet next to the mantle. It is esteemed a greater mark of nobility than the armoury, being borne at tournaments, to which none were admitted till such time as they had given proof of their nobility: sometimes it serves to distinguish the several branches of a family; and it has served, on occasion, as a distinguishing badge of factions: sometimes the crest is taken for the device; but more usually is formed of some piece of the arms. Families that exchange arms do not change their crest.

CREUX, a French term used among artificers, and literally signifying a hollow cavity, or pit, out of which something has been scooped or dug; whence it is used to signify that kind of sculpture, where the lines and figures are cut and formed within the face or plan of the plate, or matter engraved; and thus it stands in opposition to relievo, where the lines and figures are embossed, and rise prominent above the face of the matter engraved on.

CREW, the company of sailors belonging to a ship, boat, or other vessel. The sailors that are to work and manage a ship, are regulated by the number of lasts it may carry, each last making two ton. The crew of a Dutch ship, from forty to fifty lasts, is seven sailors and a swabber; from fifty to sixty lasts, the crew consists of eight men and a swabber; and thus increases at the rate of one man every ten lasts. English and French crews are usually stronger than Dutch, but always in about the same proportion. There are in a ship several particular crews or gangs, as the gun-room crew, the carpenter's crew, &c.

CRIBBAGE, a game at cards, in which no cards are to be thrown out, and the set to make sixty-one: and as it is an advantage to deal, on account of the crib, it is proper to cut for it, and he that has the least card deals. There are only two players at this game, in which the cards are dealt out one by one; the first to the dealer's antagonist, and the next to himself, and so on, till each has five; the rest being set down in view on the table. This done, the dealer lays down the two best cards he can for his crib; and his antagonist lays down the other two, the very worst in his hand, the crib being the property of the dealer. They next turn up a card from the parcel left after dealing, and then count their game thus: Any fifteen upon the cards is two; as king and five, ten and five, nine and six, eight and seven, &c. A pair is also two; a pair-royal, or three aces, kings, &c. six; a double pair-royal, or four aces, &c. twelve. Sequences of three cards, as four five and six, is three; sequences of four, four; five, five, &c. and the same holds of a flush. Knave-noddy, or of the suit turned up, is one in hand, and two to the dealer. If, after the cards for the crib are laid out, you have in your hand a nine and two sixes, that makes six, because there are two fifteens and a pair; and if a six chance to be turned up, then you have twelve in your hand, viz. the pair-royal, and three fifteens. These are to be marked with pegs, counters, or otherwise. If you happen to have sequents, as of four five and six, in your hand, and six is the turned up card, they are counted thus: first, the sequents in your hand make three; and the sequents of the four and five in your hand, added to the six turned up, make other three: there are likewise two fifteens, counting first with the six in your hand, and then with that turned up.

This done, the antagonist to the dealer plays first, suppose a six; and if the dealer can make it fifteen, by playing nine, he gains two; otherwise they play on, and he that reaches thirty one exactly, or comes nearest under it, gains two or one. Here too, in playing the cards, you may make pairs, pairs-royal, flushes, &c. which are all counted as above.

As to the crib, it is the dealer's; who may make as many as he can out of it, together with the card turned up, counted as above; if he can make none, he is said to be bilked. Thus they play and deal by turns, till the game of sixty-one is up: and if either of the gamesters reach

this before the other is forty-five, this last is said to be lurched, and the other gains a double game.

CRIME, crimen, the transgression of a law, either natural or divine, civil or ecclesiastic. Civilians distinguish between crimen and delictem. By the first, they mean capital offences, injurious to the whole community, as murder, perjury, &c. the prosecution of which was permitted to all persons, though no ways immediately interested. By the latter, they understand private offences committed against individuals, as theft, &c. By the laws, nobody was allowed to prosecute in these, except those interested.

With us, crimes are distinguished into capital, as treason, murder, robbery, &c. and common, as perjuries, &c. Again, some crimes are cognizable by the king's judges, as the above-mentioned; and others are only cognizable in the spiritual courts, as simple fornication.

CRIMSON, one of the seven red colours of the dyers. See DYEING.

CRINGLE, a small hole made in the bolt-rope of a sail, by intertwisting one of the divisions of a rope, called a strand, alternately round itself and through the strands of the bolt-rope, till it becomes threefold, and assumes the shape of a wreath or ring. The use of the cringle is generally to contain the end of some rope, which is fastened thereto for the purpose of drawing up the sail to its yard, or of extending the skirts by the means of bridles, to stand upon a side-wind. The word seems to be derived from krinckelen (Belg.), "to run into twists."

CRINODRENDRUM, a genus of the class and order monadelphia decandria. There is no calyx; the corolla is bell-shaped, six-petalled: capsule one-celled, gaping elastically at top. There is one species, a native of Chili.

CRINUM, a genus of the monogynia order, in the hexandria class of plants; and in the natural method ranking under the ninth order, spathaceæ. The corolla is funnel-shaped, monopetalous, and sexpartite, with three alternate segments having hooked appendages; the germen is covered in the bottom of the corolla, the stamina standing asunder. They are very beautiful green-house plants, rising two or three feet high; each of them crowned by a large umbellate cluster of spathaceous, monopetalous, long, funnel-shaped flowers, blue, white, or striped, having a very fragrant smell. They are propagated by offsets. There are six species.

CRITHMUM, samphire; a genus of the digynia order, in the pentandria class of plants; and in the natural method ranking under the 45th order, umbellatæ. The fruit is oval and compressed: the florets equal. There are three species, the principal of which is the maritimum, or common maritime samphire. It has a fibrous penetrating root; thick, succulent, branchy stalks, rising two feet high; winged fleshy leaves, consisting of many small spear-shaped lobes; with round yellow flowers growing in umbels. It is produced naturally on the sea-coasts, among the gravel and rocks. Its leaves are an excellent pickle used for sauces, and are by many eaten raw in salads. It is of a saltish relish, palatable, and comfortable to the stomach. It is not very easily preserved in gardens. It must be sown on gravelly or rocky ground, half an inch deep; in which situation the plants will come up, and last some years. The leaves of this plant are said also to be aperient and diuretic.

CRISP-LEAF, among botanists, is one folded over and over at the edges, which are always serrated, dentated, or lacerated. It is otherwise called curled.

CRITICISM may be regarded as embracing three separate branches: 1st. The establishing rules and principles for correct composition; such are the incomparable treaties of Cicero and Quinctilian upon oratory, and of Longinus on the sublime. In English we have many valuable essays and treatises of this class. The prefaces of Mr. Dryden are a rich mine of critical principles finely illustrated. Some of Mr. Addison's papers in the Spectator, and Mr. Pope's and Dr. Johnson's prefaces to Shakspeare, are excellent specimens of rational criticism. In more modern times we have had some excellent compendiums of criticism: among which lord Kaime's Elements of Criticism, Dr. Blair's Lectures, Dr. Priestley's Lectures on Oratory and Criticism, and particularly bishop Lowth's Lectures on the Sacred Poetry of the Hebrews, deservedly hold a very high rank. See the articles RHETORIC and POETRY.

The second branch of critical science relates to the commenting upon ancient authors, explaining difficult passages, and elucidating their beauties. Eustathius and the scholiasts, Vida, Scaliger, the Stephenses, and above all, the gentlemen of Port Royal, have been great benefactors to the public in this way. The delphin and variorum editions of the classics do great credit to the learned persons by whom they were edited. Many editions of Shakspeare have been published with critical notes. Mr. Theobald's was better than Mr. Pope's except for the preface. Dr. Warburton entirely failed, for the same reason as Dr. Bently in his edition of Milton, viz. indulging too freely in conjectural criticism. Dr. Johnson's explanatory notes on Shakspeare are excellent; and the profound reading of Malone, Steevens, and Farmer, in British and Saxon literature, have been excellently applied to the illustration of the first of dramatic poets.

The third branch of criticism regards the forming a correct judgment of the merits and demerits of cotemporary witers. In this every man of education ought to qualify himself to see with his own eyes, and determine with his own understanding; and this is to be effected by the attentive study of the best works, ancient and modern, on the general principles of criticism (see above.) For to form our judgment on that of any other men is a species of literary slavery. The various partialities and conflicting interests by which mankind are governed, render it also very unsafe to rest our opinion upon that of others; and it is peculiarly unfortunate that this department of literature is seldom exercised by persons adequate, from education and experience, to the task. Where it is, there is no reason why the name of the critic should not be as *public* as that of the author; when that is not the case, his motive will be suspected; nor can the reader assent to observations from an authority, of the competency of which he is not assured. For these reasons but little credit is attached, except in remote country places, to anonymous criticism.

The great vices of modern criticism are pertness and flippancy. Writers of this class seem to consider the

study of Joe Miller as of more importance to their craft than that of Quinctilian; and a readiness in the art of punning, as the highest praise and principal qualification of a critic.

CROCODILE. See LACERTA.

CROCODILE, *fossil*, one of the greatest curiosities in the fossil world which late ages have produced. It is the skeleton of a large crocodile, almost entire, found at a great depth under ground, bedded in stone. This was in the possession of Linkius, who wrote many pieces of natural history, and particularly an accurate description of this curious fossil. It was found in the side of a large mountain in the midland part of Germany, and in a stratum of black fossile stone, somewhat like our common slate, but of a coarser texture, the same with that in which the fossil fish in many parts of the world are found. The skeleton had the back and ribs very plain, and was of a much deeper black than the rest of the stone; as is also the case in the fossil fishes which are preserved in this manner. The part of the stone where the head lay was not found, this being broken off just at the shoulder, but that irregularly; so that in one place a part of the back of the head was visible in its natural form. The two shoulder-bones were very fair, and three of the feet were well preserved; the legs were of their natural shape and size, and the feet preserved even to the extremities of the five toes of each.

CROCODILE, *crocodilus*, in rhetoric, a captious and sophistical kind of argumentation, contrived to seduce the unwary, and draw them speciously into a snare. It has its name crocodile from the following occasion, invented by the poets: A poor woman begging a crocodile, that had caught her son walking by the river-side, to spare and restore him, was answered, that he would restore him, provided that she should give a true answer to a question he should propose. The question was, Will I restore thy son or not? To this the poor woman, suspecting a deceit, sorrowfully answered, Thou wilt not; and demanded then to have him restored, because she had answered truly. Thou liest, says the crocodile: for if I restore him thou hast not answered truly: I cannot therefore restore him without making thy answer false. Under this head may be reduced the propositions called "mentientes," or "insolubiles," which destroy themselves. Such is that of the Cretan poet: "Omnes ad unum Cretenses semper mentiuntur:" "All the Cretans, to a man, always lie." Either, then, the poet lies when he asserts that the Cretans all lie, or the Cretans do not all lie.

CROCUS, *saffron*, a genus of the monogynia order, in the triandria class of plants, and in the natural method ranking under the sixth order, insatæ. The corolla is sexpartite and equal; the stigmata convoluted, or rolled spirally inwards. There are two species of this genus, which, however, comprehend many beautiful varieties.

1. The officinalis, saffron, or autumnal crocus, has a small, roundish, brown, bulbous root, compressed at the bottom. Directly from the root issue many narrow leaves, of a deep-green colour; and amidst them the flowers are protruded from a thin univalvular radical spatha; the tube of the flower is long, standing on the root, and serving as a foot-stalk to the limb or upper part, which is erect, six-parted, widens gradually upward, and grows from about three to five or six inches high. The saffron has a long-tubed blueish-purple flower, with three stigmata of a fine golden colour, which form the saffron of the shops. The varieties are the autumnal small blue crocus; deep blue, sky blue, whitish blue, many-flowered whitish blue, purple, autumnal white crocus, and autumnal yellow crocus.

2. The vernalis, or vernal crocus, the varieties of which are, small and large, and golden yellow crocuses, and the yellow black-striped, the yellow purple-striped, and double cloth of gold; the white, white purple-striped, white purple bottom, white black-striped, whitish cream-coloured, whitish ash-coloured, little narrow-leafed white, and white blue-striped crocuses. Besides these there are a great many others of a blue and purple colour finely variegated. The autumnal crocuses flower about the beginning of October, but never ripen their seeds in this country.

CROISADE, *crusade*, or *crusado*, a name given to the expeditions of the christians against the infidels, for the conquest of Palestine; so called because those who engaged in the undertaking wore a cross on their clothes, and bore one on their standard. This expedition was also called the holy war, to which people flocked in great numbers from pure devotion; the pope's bulls, and the preaching of the priests of those days, making it a point of conscience. The several nations engaged in the holy war were distinguished by the different colours of their crosses: the English wore white, the French red, the Flemish green, the Germans black, and the Italians yellow. From this enterprise several orders of knighthood took their rise. They reckon eight croisades for the conquest of the holy land; the first begun in the year 1095, at the solicitation of the Greek emperor and the patriarch of Jerusalem.

CROISIERS, *cross-bearers*, a religious order founded in honour of the invention or discovery of the cross by the empress Helena. They follow the rule of St. Augustine.

CROISSANTE, in heraldry, is said of a cross, the ends of which are fashioned like a crescent or half-moon.

CROMLECHS, in British antiquities, are huge, broad, flat stones, raised upon other stones set up on end to support them. They are common on Anglesey. These monuments are spoken of largely by Mr. Rowland, by Dr. Borlase, and by Wormius, under the name of ara, or altar. Mr. Rowland, however, is undecided in his opinion; for he partly inclines to the notion of their having been altars, partly to their having been sepulchres: he supposes them to have been originally tombs, but that in after-times sacrifices were performed upon them to the heroes deposited within. Mr. Keiller preserves an account of king Harold having been interred beneath a tomb of this kind in Denmark, and Mr. Wright discovered in Ireland a skeleton deposited under one of them. The great similarity of the monuments throughout the north, Mr. Pennant observes, evinces the same religion to have been spread in every part, perhaps with some slight deviations. Many of these monuments are both British and Danish; for we find them where the Danes never penetrated.

The cromlech, or cromleh, chiefly differs from the

kist-vaen, in not being closed up at the ends and sides, that is, in not so much partaking of the chest-like figure; it is also generally of larger dimensions, and sometimes consists of a greater number of stone: the terms cromlech and kist-vaen are however indiscriminately used for the same monument. The term cromlech is by some derived from the Armoric word crum, "crooked or bowing," and lch, "stone," alluding to the reverence which persons paid to them by bowing, Rowland derives it from the Hebrew words carem-luach, signifying "a devoted or consecrated stone." They are called by the vulgar coetne Arthor, or Arthur's quoits, it being a custom in Wales, as in Cornwall, to ascribe all great and wonderful objects to prince Arthur, the hero of those countries. See Plate XXXIX. Miscel. fig. 24.

CROSIER, or *crozier*, a shepherd's crook; a symbol of pastoral authority, consisting of a gold or silver staff, crooked at the top, carried occasionally before bishops and abbots, and held in the hand when they gave the solemn benedictions.

CROSIER, in astronomy, four stars in the southern hemisphere, in the form of a cross, serving those who sail in southern latitudes to find the antarctic pole.

CROSLET, in heraldry, is when a cross is crossed again at a small distance from each of the ends.

CROSS, *invention of the*, a festival observed May 3, by the Latin church, in memory of the empress Helena (the mother of Constantine) finding the true cross of Christ, on mount Calvary, where she caused to be erected a church for the preservation of it.

CROSS, *order of the*, an order of ladies instituted in 1668, by the empress Eleanora de Gonzagua, wife of the emperor Leopold, on occasion of the miraculous recovery of a little golden cross, in which were enclosed two pieces of the true cross, out of the ashes of a part of the palace that had been burned down: though the fire burnt the case wherein it was enclosed, and melted the crystal, it appears that the wood had not received the least damage.

CROSS, in heraldry, is defined by Guillim, an ordinary composed of fourfold lines, whereof two are perpendicular, and the other two transverse. The content of a cross is not always the same; for when it is not charged, it has only the fifth part of the field; but if it is charged, then it must contain the third part thereof. This bearing was bestowed on such as had performed, or at least undertaken, some service for Christ and the christian profession; and is therefore held by several authors the most honourable charge in all heraldry. What brought it into such frequent use, was the ancient expeditions into the holy land, the cross being the ensign of that war.

CROSS, in surveying, an instrument consisting of a brass circle, divided into four equal parts, by two lines intersecting each other at the centre: at the extremity of each line there is a sight fixed, standing perpendicularly over the line, with holes below each slit, for the better discovery of distant objects. See SURVEYING.

CROSS-BAR SHOT, a bullet with an iron bar passing through it, and standing six or eight inches out at both sides: it is used at sea for destroying the enemy's rigging.

CROSS-TREES, in a ship, four pieces of timber, bolted and let into one another across, at the head of the mast. Their use is to keep and bear the top-mast up; for the foot of the top-mast is always fastened into them.

CROSSELET, a little or diminutive cross, used in heraldry, where the shield is frequently seen covered with crosselets; also fesses and other honourable ordinaries, charged or accompanied with crosselets. Crosses frequently terminate in crosselets.

CROSSOTYLUS, a genus of the polyandria order, in the monadelphia class of plants. The calyx is quadrifid; the corolla consists of four petals; the stamina are 20 filiform filaments, almost the length of the calyx; the antheræ small and roundish; the pericarpium an hemispherical, unilocular berry, with many striæ on its upper part; the seeds numerous and roundish. There is one species, a native of the Society Isles.

CROTALARIA, *rattle-wort*, a genus of the decandria order, in the diadelphia class of plants, and in the natural method ranking under the 32d order, papilionaceæ. The legumen is turgid, inflated, and pedicellated; the filaments are connate, with a fissure on the back. There are 32 species, all of them natives of warm climates. They rise from eighteen inches to five feet in height, and are adorned with flowers of a red, blue, or yellow colour. The most remarkable species is the retusa, with simple and oblong wedged leaves. It is a native of the island of Ceylon, and some other parts of the East Indies. The flowers are yellow; the pods smooth, cylindrical, inflated, and placed horizontally; they are filled with seeds, which, when dried, and shaken by the lightest wind, produce a rattling noise; and this, by the rude inhabitants of the countries where the plant is native, is attributed to the devil, who is thought to deliver his oracles in this whimsical manner.

CROTALUM (from the Greek), synonymous with cymbalum. The name of an ancient musical instrument. See CYMBALUM.

CROTALUS, *rattle-snake*, a genus belonging to the order of amphibia serpentes, the generic character of which is, scuta on the abdomen; scuta and squamæ beneath the tail; rattle terminating the tail.

1. Crotalus horridus, or banded rattlesnake. The genus crotalus, or rattlesnake, affords the most signal examples of the powerfully destructive poison with which some of the serpent tribe are furnished; instances having frequently occurred in which the bite of these snakes has proved fatal to mankind, in the space even of a very few minutes.

Till the discovery of the western hemisphere, the knowledge of these serpents was concealed from the rest of the world: and philosophers then first beheld with amazement a reptile of the most fatal nature, furnished, as if by a peculiar institution of Providence, with an instrument capable, in general, of warning mankind of their danger in too near an approach.

The different species of rattlesnakes seem to have been generally confounded with each other; and even Catesby, who travelled in those parts of North America where it is found, seems to have been unacquainted with one of the most remarkable species; and to have particularly described the banded rattlesnake only, which he has also figured with sufficient clearness to prevent its being confounded with any other kind, though not with that minute attention to all the particulars which the

more improved state of natural history at present demands.

This species is found, in general, from three to four or five feet in length; and is of a yellowish-brown colour, marked throughout its whole length with several transverse and somewhat irregular fasciæ of deep brown, and from the head to some distance down the neck run two or three longitudinal stripes of the same colour; the head is large, flat, and covered with small scales; the rest of the upper parts with moderately large oval ones, all strongly carinated or furnished with a prominent line down the middle: the under parts are of a dingy yellowish-brown colour, marked with numerous dusky variegations and freckles: at the extremity of the tail is situated the rattle, consisting of several hard, dry, horny processes, the peculiar structure of which will be more amply described hereafter; and which, on the least disturbance or irritation, is elevated and shaken in such a manner as to cause a strong or brisk rattling sound.

"The largest rattlesnake," says Catesby, "which I ever saw, was about eight feet in length, and weighing between eight and nine pounds. They are the most inactive and slow-moving snake," adds this author, "of all others, and are never the aggressors, except in what they prey upon; for unless they are disturbed they will not bite; and when provoked they give warning by shaking their rattles."

The charming, as it is commonly called, or attractive power this snake is said to have, of drawing to it small animals, and devouring them, is generally believed in America. The manner of the process is said to be, that the animals, particularly birds and squirrels (which principally are their prey), no sooner spy the snake than they skip from spray to spray, hovering and approaching gradually nearer to their enemy; regardless of any other danger; but with distracted gestures and outcries, descend, though from the top of the loftiest trees, to the mouth of the snake, who opens his jaws, takes them in, and in an instant swallows them. This we believe to be merely an effect of fear in the victim, and the account is probably exaggerated. "With respect to the use of the rattle," says Dr. Mead, "a vulgar error has obtained, even among the learned, about it. It is commonly said that it is a kind contrivance of divine Providence, to give warning to passengers by the noise which this part makes, when the creature moves, to keep out of the way of its mischief. Now this is a mistake. It is beyond all dispute that wisdom and goodness shine forth in all the works of the creation; but the contrivance here is of another kind than is imagined. All the parts of animals are made either for the preservation of the individual, or for the propagation of its species: this before us is for the service of the individual. This snake lives chiefly upon squirrels and birds, which a reptile can never catch without the advantage of some management to bring them within its reach. The way is this. The snake creeps to the foot of a tree, and, by shaking his rattle, awakens the little creatures which are lodged in it. They are so frightened at the sight of their enemy, who fixes his lively piercing eyes upon one or other of them, that they have no power to get away, but leap about, from bough to bough, till they are quite tired, and at last, falling to the ground, they are snapped into his mouth. This is by the people of the country called charming the squirrels and birds."

Dr. Barton, professor of natural history in the university of Pennsylvania, in a memoir on the supposed fascinating power of the rattlesnake, imagines the whole to be no more than the fluttering of old birds in defence of their young, and which are themselves occasionally caught by the rattlesnake in consequence of too near an approach.

Rattlesnakes in general swarm in the less inhabited parts of North America; but are now almost extirpated in the more populous parts. None are found farther north than the mountains near lake Champlain; but they infest South America, even as far as Brasil. They love woods and lofty hills, especially where the strata are rocky or chalky: the pass near Niagara abounds with them. Being slow of motion, they frequent the sides of rills, to make prey of frogs, or such animals as resort there to quench their thirst: are generally found during summer in pairs; in winter collecting in multitudes, and retiring under ground, beyond the reach of frost: tempted by the warmth of a spring day, they are often observed to creep out weak and languid: a person has seen a piece of ground covered with them, and killed with a rod between sixty and seventy, till overpowered with the stench he was obliged to retire.

The rattlesnake is a viviparous animal, producing its young in the month of June, generally about twelve in number; and which by September acquire the length of twelve inches. It is said to practise the same extraordinary mode of preserving its young from danger as is attributed to the viper in Europe, viz. of receiving them into its mouth, and swallowing them. For this we have the attestation of M. de Beauvois, who declares himself an eye-witness of the process. This gentleman saw a large rattlesnake, which he happened to disturb in his walks, and which immediately coiled itself up, opened its jaws, and instantly five small ones, which were lying by it, rushed into its mouth. He retired, and watched the snake, and in a quarter of an hour saw her again discharge them. He then approached it a second time, when the young retired into its mouth with greater celerity than before, and the snake immediately moved off among the grass, and escaped. See Pl. XI. N. H. fig. 150.

2. Crotalus durissus, or striped rattlesnake. This species may, in general, be readily distinguished from the former by the different disposition of its colours; being of a deep brown above, with a very regularly conducted pattern of pale-yellow streaks, so disposed as to form a continued series of large rhombs or lozenges down the back, the stripes growing somewhat less distant as they descend on the sides. The size and general proportions of the animal resemble those of the former, with which indeed it appears to have been very frequently confounded. It is also a native of the same parts of America. Its bite, so far as can be ascertained by experiments made with such specimens as have been transported into Europe, appears to be equally fatal with that of the former species.

3. Crotalus dryinas, or wood rattlesnake. This is said to be of a paler or lighter tinge than the two former

species, and to be variegated with yellowish marks on the back.

4. Crotalus miliarius, or miliary rattlesnake. Mr. Catesby, the first described of this animal, seems to entertain some doubts whether it really differs from the common rattlesnake in any other respect than in colour, its prevailing tinge being grey-brown, shaded on the back with red, and marked by large black spots with white indented edges. It appears, however, to be a truly distinct species, differing not only in colour but in the smaller number of its abdominal scuta. This is the smallest species of rattlesnake yet known, rarely exceeding the length of two feet. In its general habits it resembles the preceding kinds.

CROTAPHITES, in anatomy, a muscle of the lower jaw, serving to draw it upwards.

CROTCHES, in ship-building, very crooked timbers in the hold or bread-room, from the mizen-step aft, fayed across the keelson, to strengthen the ship in the wake of the half-timbers.

Crotches, *iron*, crooked pieces of iron, used on board sloops and long-boats which go with shoulder-of-mutton sails, for the boom to lodge on.

CROTCHET, in music, one of the notes or characters of time, marked thus ♩, equal to half a minim, and double of a quaver. A dot added to the crotchet thus ♩., increases its time by one-half, that is, makes it equal to a crotchet and a half.

Crotchets, marks or characters, serving to inclose a word or sentence, which is distinguished from the rest, being generally in the form [ ], or this ( ).

CROTON, *wild ricinus*, a genus of the monadelphia order, in the monœcia class of plants, and in the natural method ranking under the 38th order, tricoccæ. The male calyx is cylindrical and quinquedentated; the corolla is pentapetalous; the stamina from 10 to 15. The female calyx is polyphyllous; no carolla; three bifid styles; the capsule trilocular; one seed. There are 53 species, of which the most remarkable are:

1. The tinctorium, or plant from which the French turnsole is made. This grows naturally in the south of France; it is an annual plant, rising about nine inches high, with an herbaceous branching stalk, with irregular or rhomboidal figured leaves, which are near two inches long. The flowers are produced in short spikes from the sides of the stalks, at the end of the branches; the upper part of the spike is composed of male flowers, having many stamina which coalesce at the bottom; the lower part has female flowers, which have each a roundish three-cornered germen; these afterwards become a roundish capsule with three lobes, having three cells, each including one roundish seed. This flowers in July; but unless the plants are brought forward on a hotbed, they do not ripen seeds in this country. From this plant is made the turnsole used for colouring wines and jellies. It is made of the juice which is lodged between the empalement and the seeds; which, if rubbed on cloths, at first appears of a lively green, but afterwards changes to a blueish-purple colour. If these cloths are put into water, and afterwards wrung, they will dye the water to a claret-colour. The rags thus dyed are brought to this country, and sold in the druggists' shops under the name of turnsole.

2. The seviferum, or tallow-tree, with rhomboidal egg-shaped leaves, pointed, smooth, and very entire. It is about the height of a cherry-tree: its leaves in form of a heart, of a deep shining red colour, and its bark very smooth. Its fruit is enclosed in a kind of pod, or cover, like a chesnut; and consists of three round white grains, of the size and form of a small nut, each having its peculiar capsule, and within that a little stone. This stone is encompassed with a white pulp, which however is not the tallow, as is erroneously supposed, for that is expressed from the kernels: and the Chinese make their candles of it; which would doubtless be as good as those in Europe, if they knew how to purify their vegetable tallow as well as we do our animal kind, and to make their wicks as well.

3. The aromaticum, with heart-shaped serrated leaves, and an arborescent stem. The bark of this tree is the same as the cascrilla and cleutheria, though these have been considered by some as distinct barks, and sold in the shops as different productions. It is a hot, acrid, aromatic bitter, resembling in appearance the Peruvian bark, but is more bitter and pungent, though not so rough and astringent. It was first introduced into Europe about the end of the last century, and seems first to have been used in Germany, where it is still in very high esteem. There it is frequently employed in intermittent fevers, in preference to the Peruvian bark, as being less subject to some inconveniences to which the latter is deemed liable. It is also said to have been employed with great success in some very dangerous epidemic fevers attended with petechiæ; and it is frequently employed with advantage in dysenteries, diarrhœas, &c. In Britain it has also been used by some practitioners. Its virtues are partly extracted by water, and totally by rectified spirit, but it is most effectual when given in substance.

4. The cascarilla, described by Linnæus as producing the officinal bark of that name, is, according to Dr. Wright, the wild-rosemary shrub of Jamaica, the bark of which has none of the sensible qualities of the true cascarilla or cleutheria above described.

[CROTONOPSIS, in botany, a genus of the monœcia pentandria class and order; the essential characters are, calix, five parted; corolla of the male, five petals; capsule ovate; there are two species, both natives of Carolina; the c. linearis, and c. elliptica. (*b*)

CROTOPHAGA, in ornithology, a genus of birds belonging to the order of picæ. There are two species, the characters of which are: the bill is thin, compressed, greatly arched, half oval, and cultrated at top; the nostrils are round; the tongue flat, and pointed at the end; the tail consists of ten feathers; and the toes are placed two and two. The most remarkable species is the ani, which is about the size of a blackbird: the colour of the whole bird is black, in some parts glossed with purple, and about the neck faintly tinged with green on the margins: the base of the bill is furnished with black bristles, which turn forwards: the eyelids have long hair-like eyelashes: the tail is six inches long, and much cuneated; and the legs are black. This species is found in Jamaica, St. Domingo, and other Islands in the West Indies; also at Cayenne, and other parts of South America. Contrary to all other birds, they have

the singularity of many lying in the same nest; to make which they all unite in concert, and, after laying their eggs, sit on them close to each other to hatch them, each amicably striving to do the best for the general good; and when the young are hatched, the parents, without reserve, do their best to feed the whole flock. Still a greater singularity occurs, which is, that as soon as each female lays her eggs she covers them with leaves, doing the same thing whenever she is obliged to leave the nest for food: this might be necessary in a cold climate; but why it should be wanted in a hot one seems not clear, especially as it has not been observed in other birds. The famale has two broods in a year, except accidents happen; in which case she has been known to make three nests. The eggs are about the size of those of a pigeon, of a sea-green colour, spotted at the ends. Their food is various; worms, insects, fruits, and grain, according to the season. There is a variety called the greater ani, which is about the size of a jay, differing no otherwise from the former but in size. They ought, however, to be considered as two distinct species: for they never mix together, though each has the same manners, with this difference only, that the smaller frequent the savannas, the larger only the salt-marshes near the sea-coasts. It is said that they are easily made tame, and will learn to talk like parrots. The male and female are both alike. Both species are easy to be shot, not being so wild as many other birds; but are known to chatter much on the sight of a man, though they do not fly to a great distance.

CROUP *of a horse*, in the manege, the extremity of the reins above the hips.

CROW. See CORVUS.

CROW, in mechanics, a kind of iron lever with a claw at one end, and a sharp point at the other: used for heaving or purchasing great weights.

CROW'S BILL, among surgeons, a kind of forceps, for drawing bullets and other foreign bodies out of wounds.

CROW'S FEET, in the military art, machines of iron, having four points, each about three or four inches long, so made that whatever way they fall there is still a point up: they are thrown upon breaches, or in passes where the enemy's cavalry are to march, proving very troublesome, by running into the horses' feet, and laming them.

CROW'S FEET, in a ship, small lines or ropes, sometimes eight or ten, reeved through the dead-men's-eyes; and scarcely of any other use than to make a show of small rigging. They are usually placed at the bottom of the back-stays of the fore-top-mast, mizen-top-mast, and top-gallant-mast. See Plate XXXIX. Miscel. fig. 25.

CROW-NET, is an invention for catching wild-fowl in the winter season, and may be used in the day-time. This net is made of double thread, or fine pack-thread; the meshes should be two inches wide, the length about ten yards, and the depth three; it must be verged on the side with good strong cord, and stretched out very stiff on long poles prepared for that purpose. When you come to the place where you would spread your net, open it, and lay it out at its full length and breadth: then fasten the lower end of the net all along the ground, so as only to move it up and down; the upper end of the net must stand extended on the long cord, the further end being staked first to the earth by a strong cord about five yards distant, from the net. Place this cord in an even line with the lower edge of the net. The other end must be at least 25 yards distance, to reach into some natural or artificial shelter, by the means of which you may lie concealed from the fowl, otherwise no good success can be expected. The net must be placed in such exact order that it may give way to play on the fowl on the least pull of the cord, which must be done smartly, lest the fowl should prove too quick for you. This net may be used for pigeons, crows, or other birds, on corn-fields newly sown; as also in stubble-fields, provided the stubble conceals the net from the birds.

CROWN, in heraldry, is used for the representation of that ornament, in the mantling of an armoury, to express the dignity of persons.

CROWN, *the imperial*, is a bonnet or tiara, with a semicircle of gold, supporting a globe with a cross at top.

CROWN, *the British*, is adorned with four crosses, between which there are four fleurs-de-lis: it is covered with four diadems, which meet at a little globe supporting a cross.

CROWN, *the French*, was a circle of eight fleurs-de-lis, encompassed with six diadems, bearing at top a double fleur-de-lis, which was the crest of France.

CROWN, *the Spanish*, is adorned with large indented leaves, and covered with diadems terminating in a globe, surmounted with a cross.

The crowns of almost all other kings are adorned with large leaves, bordered with four, six, or eight diadems, with a globe and cross at top.

CROWN, *the papal*, is composed of a tiara and a triple crown encompassing it, with two pendants like the bishops' mitres. These crowns represent the pretended triple capacity of the pope, as high-priest, supreme judge, and sole legislator of Christians.

CROWN, *electoral*, or coronet, is a scarlet cap turned up with ermine, and closed with a semicircle of gold, all covered with pearls, with a globe at top, surmounted with a golden cross.

CROWNS *of British princes of the blood*. 1. The prince of Wales's crown consists alternately of crosses and fluers-de-lis, with one arch, in the middle of which are a ball and cross, as in the royal diadem. 2. That of all the younger sons and brothers of the king, consist likewise of crosses and fleurs-de-lis alternately, but without any arch, or being surmounted with a globe and cross at top. 3. That of the other princes of the blood consists alternately of crosses and leaves like those in the coronet of dukes.

CROWNS *of noblemen*, are a duke's, composed of leaves of smallage, or parsley: that of a marquis, of flowers and pearls placed alternately: an earl's has no flowers about the circle, like the duke's and marquis's, but only points rising, and a pearl on every one of them: a viscount has neither flowers nor points raised above the circle, like the other superior degrees, but only pearls placed on the circle itself without any limited number: a baron's has only six pearls on the golden border, not raised, to distinguish him from the earls; and the number of them limited, to show he is inferior to the viscount.

Crown, in commerce, a general name for coins both foreign and domestic, which are of, or very near, the value of five shillings sterling. See Coin.

Crown, in architecture, denotes the uppermost member of the cornice, called also corona, and larmier.

Crown, in astronomy, a name given to two constellations, the one called borealis, the other meridionalis.

Crown is used also for the clerical tonsure, which is the mark and character of ecclesiastics of the Romish church. It is a little circle of hair shaved from the crown of the head, more or less large, according to the quality of the orders received. That of a mere clerk is the smallest, that of priests and monks the largest.

[Crown, in geometry, is the space inclosed between the two peripherys of two concentric circles: the area of it may be found by multiplying its breadth by half the sum of the bounding perimeters, which may be proved thus: Put the circumference of the outer circle $= c$ and $a =$ its radius, also $r =$ the radius of the inner circle, then $\frac{ac}{2}$ = the area of the greater circle, and $a^2 : r^2 :: \frac{ac}{2} : \frac{cr^2}{2a}$ = the area of the inner circle; then $\frac{ac}{2} - \frac{cr^2}{2a}$ = (the area of the crown) $= a^2 - r^2 \times \frac{c}{2a} = \overline{a+r} \times \overline{a-r} \times \frac{c}{2a}$. But $a-r =$ the breadth and $a+r \times \frac{c}{2a} =$ half the sum of the bounding perimeters. Because $a : r :: c : \frac{rc}{a}$ = the perimeter of the lesser circle, and $\frac{rc}{a} + c \times \frac{1}{2} = \frac{rc+ac}{2a} = r + a \times \frac{c}{2a}$. Therefore the rule is manifest. (r)

Crown *of colours*, certain coloured rings which like halos appear about the body of the sun or moon, but of the colours of the rainbow, and at a less distance than the common halos. These crowns sir Isaac Newton has shown to be made by the sun's shining in a fair day, or the moon in a clear night, through a thin cloud of globules of water or hail all of the same bigness. And according as the globules are greater or less, the diameters of these crowns will be larger or smaller; and the more equal these globules are to one another, the more crowns of colours will appear, and the colours will be the more lively.

Crown-office. The court of king's bench is divided into the plea side and the crown side. In the plea side it takes cognizance of civil causes; in the crown side it takes cognizance of criminal causes, and is therefore called the crown-office. In the crown-office are exhibited informations in the name of the king, for crimes and misdemeanors at common law, as in the case of batteries, conspiracies, libelling, &c. for which the offender is liable to pay a fine to the king.

Crown-post, in architecture, a post which in some building stands upright in the middle between two principal rafters, and from it there go struts or braces to the middle of each rafter. It is sometimes called a king's piece, or joggle piece.

Crown-wheel *of a watch*, the upper wheel next the balance, which by its motion drives the balance, and in royal pendulums is called the swing-wheel.

Crown-work, in fortification, an outwork having a very large gorge, generally the length of the curtin of the place, and two long sides terminating towards the field in two demibastions, each joined by a particular curtin to a whole bastion, which is the head of the work. The crown-work is intended to inclose a rising ground, or to cover the head of a retrenchment.

CROWTH, or Cruth, a musical instrument formerly much in use among the common people in Wales. It resembles in some respects the violin. See Pl. XXXIX. Miscel. fig. 26.

CRUCIANELLA, petty madder, a genus of the monogynia order, in the tetrandria class of plants; and in the natural method ranking under the 47th order, stellatæ. The corolla is monopetalous and funnel-shaped, with a filiform tube and a tailed border; the calyx is diphyllous, and there are two linear seeds. There are nine species, natives of the southern parts of Europe; but none of them possessed of any remarkable quality.

CRUCIBLE, a chemical vessel made of earth, and so tempered and baked as to endure the greatest fire. They are used to melt metals, and to flux minerals, ores, &c. See Chemistry.

CRUCITA, or cruzita, a genus of the digynia order, in the tetrandria class of plants, and in the natural method ranking with those the order of which is doubtful. The interior calyx is tetraphyllous, the exterior calyx triphyllous; there is no corolla, and only one seed. There is one species.

CRURÆUS, or *cruræus musculus*. See Anatomy.

CRURAL, in anatomy, an epithet given to the artery which conveys the blood to the crura or legs, and to the vein by which this blood returns towards the heart. See Anatomy.

CRUSCA, an Italian term signifying bran, is in use among us to denote the celebrated academy called Della Crusca, established at Florence, for purifying and perfecting the Tuscan language.

CRUST. By crusts we understand those bony coverings of which the whole external surface of crabs, lobsters, and other similar sea-animals, is composed. These consists of, 1. Cartilaginous substance, possessing the properties of coagulated albumen. 2. Carbonate of lime. 3. Phosphat of lime. By the presence of the phosphat of lime, they are distinguished from bones. Thus the crusts lie as an intermediate substance between bones and shells, partaking of the properties and constitution of each. The shells of the eggs of fowls must be referred likewise to the class of crusts, since they contain both phosphat and carbonat of lime; the animal cement in them, however, is much smaller in quantity. From the experiments of Berniard and Hatchett, it is extremely probable that the shells of snails are composed likewise of the same ingredients, phosphat of lime having been detected in them by these chemists.

Mr. Hatchett examined the crust of crabs, lobsters,

prawns, and cray-fish. When immersed in diluted nitric acid, these crusts effervesced a little, and gradually assumed the form of a yellowish-white soft elastic cartilage, retaining the form of the crust. The solution yielded a precipitate to acetat of lead, and ammonia threw down phosphat of lime. Carbonat of ammonia threw down a much more copious precipitate of carbonat of lime. On examining the crust which covers different species of echini, Mr. Hatchett found it correspond with the other crusts in its composition. Some species of star-fish yielded phosphat of lime, others none: hence the covering of that genus of animals seems to be intermediate between shell and crust.

With these observations of Mr. Hatchett the analysis of Merat-Guillot corresponds. From lobster-crust he obtained

60 carbonat of lime
14 phosphat of lime
26 cartilage

100.

One hundred parts of cray-fish crust contain
60 carbonat of lime
12 phosphat of lime
28 cartilage

100.

One hundred parts of hen's egg-shells contain
89.6 carbonat of lime
5.7 phosphat of lime
4.7 animal matter

100. 0

CRUSTACEOUS *fish*, in natural history, are those covered with shells consisting of several pieces or scales; as those of crabs, lobsters, &c. These are usually softer than the shells of the testaceous kind, which consist of a single piece, and generally are thicker and stronger than the former; such as those of the oyster, scallop, cockle, &c. Dr. Woodward observes, in his Natural History, that of all the shells found in beds, and of all the different matters dug out of the earth, there are scarcely any of the crustaceous kind: the reason he gives for it is, that these being much lighter than the rest, must have floated on the surface at the time of the Deluge, when all the strata were formed, and there have corrupted and perished.

CRYPSIS, a genus of the diandria digynia class and order. The calyx is a glume, two-valved, one-flowered; corolla glume, two-valved, awnless. There is one species, a grass of Siberia.

CRYPTOCEPHALUS, a genus of insects of the coleoptera class; antennæ filiform; feelers four; thorax margined; shells immarginate; body somewhat cylindrical. This is a very extensive genus, and consists of 268 species. See Pl. N. H. figs. 151, 152.

CRYPTOGAMIA, one of Linnæus's classes of plants, the organs of fructification of which are either concealed within the fruit itself, or so minute as to escape observation. It embraces 4 orders; filices, musci, algæ, and fungi, which see.

CRYPTOSTOMUM, a genus of the pentandria class and order. The calyx is five-cleft; tube of corolla inserted into the throat of the calyx; borders five-cleft; nect. five-toothed; berry, seeds scarred. There is one species, a shrub of Guiana.

CRYSTAL, in natural history, the name of a very large class of fossils, hard, pellucid, and naturally colourless.

CRYSTALLIZATION. The word crystal originally signified ice; but it was afterwards applied by the ancients to crystallized silica, or rock crystal; because, as Pliny informs us, they considered that body as nothing else than water congealed by the action of cold. Chemists afterwards applied the word to all transparent bodies of a regular shape; and at present it is employed to denote in general the regular figures which bodies assume when their particles have full liberty to combine according to the laws of cohesion. These regular bodies occur very frequently in the mineral kingdom, and have long attracted attention on account of their great beauty and regularity. By far the greater number of the salts assume a crystalline form; and as these substances are mostly soluble in water, we have it in our power to give the regular shape of crystals in some degree at pleasure.

All the substances with which we are acquainted may be divided into solid, liquid, and gaseous. Crystals are obviously confined to the first set, the fluidity of the two last rendering them incapable of retaining a regular form; but many of them may be made to assume a solid state, and in that case they usually crystallize. Most solid bodies either occur in the state of crystals, or are capable of being made to assume that form. Now it has long been observed by chemists and mineralogists, that there is a particular form which every individual substance always affects when it crystallizes: this indeed is considered as one of the best marks for distinguishing one substance from another. Thus common salt is observed to assume the shape of a cube; and alum that of an octahedron, consisting of two four-sided pyramids, applied base to base. Saltpetre affects the form of a six-sided prism; sulphat of magnesia, that of a four-sided prism; and carbonat of lime is often found in the state of a rhomboid. Not that every individual substance always uniformly crystallizes in the same form; for this is liable to considerable variations, according to the circumstances of the case; but there are a certain number of forms peculiar to every substance; and the crystals of that substance, in every case, adopt one or other of these forms, and no other; and thus common salt, when crystallized, has always either the figure of a cube or octahedron, or some figure reducible to these.

As the particles of bodies must be at liberty to move before they crystallize, it is obvious that we cannot reduce any bodies to the state of crystals, except those which we are able to make fluid. Now there are two ways of rendering bodies fluid, namely, solution in liquid, and fusion by heat. These of course are the only methods of forming crystals in our power.

Solution is the common method of crystallizing salts. They are dissolved in water: the water is slowly evaporated; the saline particles gradually approach each other, combine together, and form small crystals; which become constantly larger by the addition of other particles, till at

last they fall by their gravity to the bottom of the vessel. Or a saturated solution being prepared in hot water, it is set by to cool. On the escape of the caloric, by which, in fact, the solution was in great part accomplished, the salt crystallizes. Such salts commonly form in groups, attached to the sides or bottom of the vessel, or depending from a pellicle. They usually contain more water of crystallization than the former class.

There are many substances, however, neither soluble in water nor other liquids, which, notwithstanding, are capable of assuming a crystalline form. This is the case with the metals, with glass, and some other bodies. The method employed to crystallize them is fusion, which is a solution by means of caloric alone. By this method particles are separated from one another; and if the cooling proceeds gradually, they are at liberty to arrange themselves in regular crystals.

To obtain large artificial crystals of a regular shape requires considerable address and much patient attention. This curious branch of practical chemistry has been much improved by Mr. Leblanc; who has not only succeeded in obtaining regular crystals of almost any size at pleasure, but has made many interesting observations on crystallization in general. His method is as follows: The salt to be crystallized is dissolved in water, and evaporated to such a consistency that it shall crystallize on cooling. Set it by, and when quite cold pour the liquid part from the mass of crystals at the bottom, and put it into a flat-bottomed vessel. Solitary crystals form at some distance from each other, and these may be observed gradually increasing. Pick out the most regular of these, and put them into a flat-bottomed vessel at some distance from each other, and pour over them a quantity of liquid obtained in the same way by evaporating a solution of the salt till it crystallizes on cooling. Alter the position of every crystal once at least every day with a glass rod, that all the faces may be alternately exposed to the action of the liquid: for the face on which the crystal rests never receives any increment. By this process the crystals gradually increase in size. When they have acquired such a magnitude that their form can easily be distinguished, the most regular are to be chosen, or those having the exact shape which we wish to obtain; and each of them is to be put seperately in a vessel filled with a portion of the same liquid, and turned in the same manner several times a day. By this treatment they may be obtained of almost any size we think proper. After the crystal has continued in the liquid for a certain time, the quantity of salt held in solution becomes so much diminished, that the liquid begins to act upon the crystal and re-dissolves it. This action is first perceptible on the angles and edges of the crystal. They become blunted, and gradually lose their shape altogether. Whenever this begins to be perceived, the liquid must be poured off, and a portion of new liquid put in its place; otherwise the crystal is infallibly destroyed. Mr. Leblanc has observed, that this singular change begins first at the surface of the liquid, and extends gradually to the bottom; so that a crystal, if large, may be often perceived in a state of increase at its lower end, while it is disappearing at its upper extremity. Mr. Leblanc even affirms that saline solutions almost always increase in density according to their depth from the surface.

It has been observed, that those salts which crystallize upon cooling, do not assume a crystalline form so readily if they are allowed to cool in close vessels. If a saturated solution of sulphat of soda, for instance, in hot water, is put into a phial, corked up closely, and allowed to cool without being moved, no crystals are formed at all; but the moment the glass is opened the salt crystallizes with such rapidity that the whole of the solution in a manner becomes solid. It seems then that the caloric, or rather the last portions of it, cannot be carried off without the air or the atmospherical pressure in the liquid.

Not only salts, but water itself, which commonly crystallizes at 32°, may be made to exhibit the same phenomenon: it may be cooled much lower than 32 degrees without freezing. This, as Dr. Black has completely proved depends entirely upon the retention of caloric.

The phenomena of crystallization seem to have attracted but little of the attention of the ancient philosophers. Their theory, indeed, that the elements of bodies possess certain regular geometrical figures, may have been suggested by these phenomena; but we are ignorant of their having made any attempt to explain them. The schoolmen ascribed the regular figure of crystals to their substantial forms, without giving themselves much trouble about explaining the meaning of the term. This notion was attacked by Boyle; who proved that crystals are formed by the mere aggregation of particles. But it still remained to explain why that aggregation took place; and why the particles united in such a manner as to form regular figures.

The aggregation is evidently the consequence of attraction, but to explain the cause of the regular figures is a more difficult task. Newton has remarked, that the particles of bodies, while in a state of solution, are arranged in the solvent in regular order and at regular distances; the consequence of which must be, that when the force of cohesion becomes sufficiently strong to separate them from the solvent, they will naturally combine in groups, composed of those particles which are nearest each other. Now all the particles of the same body must be supposed to have the same figures: and the combination of a determinate number of similar bodies must produce similar figures. Hauy has made it exceedingly probable that these integrant particles always combine in the same body in the same way; that is to say, that the same faces, or the same edges, always attach themselves together; but that these differ in different crystals. This can scarcely be accounted for, without supposing that the particles of bodies are endowed with a certain polarity which makes them attract one part of a different particle and repel the other parts. This polarity would explain the regularity of crystallization; but it is itself inexplicable.

It is remarkable that crystals not only assume regular figures, but are always bounded by plane surfaces. It is very rarely indeed that curved surfaces are observed in these bodies; and when they are, the crystals always give unequivocal proofs of imperfection. But this constant tendency towards plane surfaces is inconceivable, unless the particles of which the crystals are composed are themselves regular figures, and bounded by plane surfaces.

If the figure of crystals depends upon the figure of their integrant particles, and upon the manner in which they combine, it is reasonable to suppose that the same parti-

cles when at full liberty, will always combine in the same way, and consequently that the crystals of every particular body will be always the same. Nothing at first sight can appear farther from the truth than this. The different forms which the crystals of the same body assume are often very numerous, and exceedingly different from each other. Carbonat of lime, for instance, has been observed crystallized in no fewer than forty different forms, fluat of lime in eight different forms, and sulphat of lime in nearly an equal number.

But this inconsistency is not so great as might at first sight appear. Romé de Lisle has shown that every body susceptible of crystallization has a particular form which it most frequently assumes, or at least to which it does most frequently approach. Bergman has demonstrated, that this primitive form, as Hauy has called it, very often lies concealed in those very crystals which appear to deviate farthest from it. And Hauy has demonstrated, that all crystals either have this primitive form, or at least contain it as a nucleus within them; for it may be extracted out of all of them by a skilful mechanical division. See Plate XXXVIII. Crystallization.

Happening to take up an hexangular prism of calcareous spar, or carbonat of lime, which had been detached from a group of the same kind, he observed that a small portion of the crystal was wanting, and that the fracture presented a very smooth surface. Let *a b c d e f g h* (fig. 1.) be the crystal: the fracture lay obliquely as the trapezium *p s u t*, and made an angle of 135 degrees, both with the remainder of the base *a b c s p h*, and with *t u e f*, the remainder of the side *i n e f*. Observing that the segment *p s u t i n* thus cut off had for its vertex *i n*, one of the edges of the base *a b c n i h* of the prism, he attempted to detach a similar segment in the part to which the next edge *c n* belonged; he employed for that purpose the blade of a knife, directed in the same degree of obliquity as the trapezium *p s u t*, and assisted by the strokes of a hammer. He could not succeed: but on making the attempt upon the next edge *b c*, he detached another segment, precisely similar to the first, and which had for its vertex the edge *b c*. He could produce no effect on the next edge *a b;* but from the next following, *a h*, he cut a segment similar to the other two. The sixth edge likewise proved refractory. He then went to the other base of the prism, *d e f g k r*, and found that the edges which admitted sections similar to the preceding ones were not the edges *e f*, *d r*, *g k*, corresponding with those which had been found divisible at the opposite base, but the intermediate edges *d e*, *k r*, *g f*. The trapezium *l q y v* represents the section of the segment which had *k r* for its vertex. This section was evidently parallel to the section *p s u t*, and the other four sections were also parallel two and two. These sections were, without doubt, the natural joinings of the layers of the crystal; and he easily succeeded in making others parallel to them, without its being possible for him to divide the crystal in any other direction. In this manner he detached layer after layer, approaching always nearer and nearer the axis of the prism, till at last the base disappeared altogether, and the prism was converted into a solid OX (fig. 2), terminated by twelve pentagons parallel two and two; of which those at the extremities, that is to say, ASRIO, IGEDO, BAODC, at one end, and FKNPQ, MNPXU, ZQPXY, at the other, were the result of mechanical division, and had their common vertices O, P, situated at the entrance of the bases of the original prism. The six lateral pentagons RSUXY, ZYRIG, &c. were the remains of the six sides of the original prism.

By continuing sections parallel to the former ones, the lateral pentagons diminished in length; and at last the points R G coinciding with the points Y Z, the points S R with the points U Y, &c. there remained nothing of the latteral pentagons but the triangles, YIZ, UXY, &c (fig. 3.). By continuing the same sections, these triangles at last disappeared, and the prism was converted into the rhomboid, *a e* (fig. 4.).

So unexpected a result induced him to make the same attempt upon more of these crystals; and he found that all of them could be reduced to similar rhomboids. He found also, that the crystals of other substances could be reduced in the same manner to certain primitive forms; always the same in the same substances, but every substance having its own peculiar form. The primitive form of fluat of lime, for instance, was an octahedron; of sulphat of barytes, a prism with rhomboidal bases; of feltspar, an oblique-angled parallelopiped, but not rhomboidal; of adamantine spar, a rhomboid, somewhat acute; of blende, a dodecahedron, with rhomboidal sides; &c.

These primitive forms must depend upon the figures of the integrant particles composing these crystals, and upon the manner in which they combine with each other. Now by continuing the mechanical division of the crystal, by cutting off slices parallel to each of its faces, we must at last reduce it to so small a size that it shall contain only a single integrant particle; consequently this ultimate figure of the crystal must be the figure of the integrant particles of which it is composed. The mechanical division, indeed, cannot be continued so far, but it may be continued till it can be demonstrated that no subsequent division can alter its figure; consequently it can be continued till the figure which it assumes is similar to that of its integrant particles.

Hauy has found that the figure of the integrant particles of bodies, as far as experiment has gone, may be reduced to three; namely,

1. The parallelopiped, the simplest of the solids, whose faces are six in number, and parallel two and two.

2. The triangular prism, the simplest of prisms.

3. The tetrahedon, the simplest of pyramids. Even this small number of primitive forms, if we consider the almost endless diversity of size, proportion, and density, to which particles of different bodies, though they have the same figure, may still be liable, will be found fully sufficient to account for all the differences in cohesion, and heterogeneous affinity, without having recourse to different absolute forces.

These integrant particles, when they unite to form the primitive crystals, do not always join together in the same way. Sometimes they unite by their faces, and at other times by their edges, leaving considerable vacuities between each. This explains why integrant particles, though they have the same form, may compose primitive crystals of different figures.

Mr. Hauy has ascertained, that the primitive forms of crystals are six in number; namely,

1. The parallelopiped; which includes the cube, the rhomboid, and all solids terminated by six faces, parallel two and two.
2. The regular tetrahedron.
3. The octahedron with triangular faces.
4. The six-sided prism.
5. The dodecahedron terminated by rhombs.
6. The dodecahedron with isosceles triangular faces.

Each of these may be supposed to occur as the primitive form or the nucleus in a variety of bodies; but those only which are regular, as the cube of the octahedron, have hitherto been found in any considerable number.

But bodies, when crystallized, do not always appear in the primitive form; some of them indeed very seldom affect that form, and all of them have a certain latitude and a certain number of forms which they assume occasionally as the primitive form. Thus the primitive form of fluat of lime is the octahedron; but that salt is often found crystallized in cubes, in rhomboidal dodecahedrons, and in other forms. All these different forms which a body assumes, the primitive excepted, have been denominated by Hauy secondary forms. Now what is the reason of this latitude in crystallizing? why do bodies assume so often these secondary forms?

To this it may be answered:

1st, That these secondary forms are sometimes owing to the variations in the ingredients which compose the integrant particles of any particular body. Alum, for instance, crystallizes in octahedrons; but when a quantity of alumina is added, it crystallizes in cubes; and when there is an excess of alumina, it does not crystallize at all. If the proportion of alumina vary between that which produces octahedrons and what produces cubic crystals, the crystals become figures with fourteen sides, six of which are parallel to those of the cube and eight to those of the octahedron; and according as the proportions approach nearer to those which form cubes or octahedrons, the crystals assume more or less of the form of cubes or octahedrons. What is still more, if a cubic crystal of alum is put into a solution that would afford octahedral crystals, it passes into an octahedron: and, on the other hand, an octahedral crystal put into a solution that would afford cubic crystals becomes itself a cube. Now, how difficult a matter it is to proportion the different ingredients with absolute exactness, must appear evident to all.

2d, The secondary forms are sometimes owing to the solvent in which the crystals are formed. Thus if common salt is dissolved in water, and then crystallized, it assumes the form of cubes; but when crystallized in urine, it assumes the form not of cubes, but of regular octahedrons. On the other hand, muriat of ammonia, when crystallized in water, assumes the octahedral form, but in urine it crystallizes in cubes.

3d, But even when the solvent is the same, and the proportion of ingredients, as far as can be ascertained, exactly the same, still there are a variety of secondary forms which are usually found to make their appearance. These secondary forms have been happily explained by the theory of crystallization for which we are indebted to the sagacity of Mr. Hauy; a theory which, for its ingenuity, clearness, and importance, must ever rank high, and which must be considered as one of the greatest acquisitions which mineralogy and even chemistry have hitherto attained.

According to this theory, the additional matter which envelopes the primitive nucleus consists of thin slices or layers of particles laid one above another upon the faces of that nucleus; and each layer decreasing in size, in consequence of the abstraction of one or more rows of integrant particles from its edges or angles.

Let us suppose that ABFG (fig. 6.) is a cube composed of 729 small cubes: each of its sides will consist of 81 squares, being the external sides of as many cubic particles, which together constitute the cube. Upon ABCD, one of the sides of this cube, let us apply a square lamina, composed of cubes equal to those of which the primitive crystal consists. It will of course be composed of 49 cubes, 7 on each side; so that its lower base *o n f g* (fig. 7.) will fall exactly on the square marked with the same letters in fig. 6.

Above this lamina let us apply a second, *l m p u* (fig. 10.) composed of 25; it will be situated exactly above the square marked with the same letters (fig. 6.) Upon this second let us apply a third lamina, *v x y z* (fig. 8.), consisting only of 9 cubes; so that its base shall rest upon the letters *v x y z* (fig. 6.) Lastly, on the middle square *r* let us place the small cube *r* (fig. 5.), which will represent the last lamina.

It is evident that by this process a quadrangular pyramid has been formed upon the face ABCD (fig. 6), the base of which is this face, and the vertex the cube *r* (fig. 5). By continuing the same operation upon the other five sides of the cube, as many similar pyramids will be formed; which will envelope the cube on every side.

It is evident, however, that the sides of these pyramids will not form continued planes, but that, owing to the gradual diminution of the laminæ of the cubes which compose them, these sides will resemble the steps of a stair-case. We can suppose however (what must certainly be the case), that the cubes of which the nucleus is formed are exceedingly small, almost imperceptible; that therefore a vast number of laminæ are required to form the pyramids, and consequently that the channels which they perform are imperceptible. Now DCBE (fig. 9.) being the pyramid resting upon the face ABCD (fig. 6.), and CBOG (fig. 9.) the pyramid applied to the next face BCGH (fig. 6.), if we consider that every thing is uniform from E to O (fig. 9.), in the manner in which the edges of the laminæ of superposition (as the abbe' Hauy calls the laminæ which compose the pyramids) project beyond each other, it will readily be conceived that the face CEB of the first pyramid ought to be exactly in the same plane with the face COB of the adjacent pyramid, and that therefore the two faces together will form one rhomb ECOB. But all the sides of the six pyramids amount to 24 triangles similar to CEB; consequently they will form 12 rhombs, and the figures of the whole crystal will be a dodecahedron.

Thus we see that a body which has the cube for the primitive form of its crystals, may have a dodecahedron for its secondary form. The formation of secondary crystals, by the superposition of laminæ gradually decreasing in size, was first pointed out by Bergman. But Hauy has carried the subject much farther: he has not only

ascertained all the different ways by which these decrements of the laminæ may take place, but pointed out the method of calculating all the possible varieties of secondary forms which can result from a given primitive form; and consequently of ascertaining whether or not any given crystal can be the secondary form of a given species.

The decrements of the laminæ which cover the primitive nucleus in secondary crystals are of four kinds:

1. Decrements on the edges, that is, on the edges of the slices which correspond with the edges of the primitive nucleus.

2. Decrements on the angles; that is to say, parallel to the diagonals of the faces of the primitive nucleus.

3. Intermediate decrements; that is to say, parallel to lines situated obliquely between the diagonals and edges of the primitive nucleus.

4. Mixed decrements. In these the superincumbent slices, instead of having only the thickness of one integrant particle, have the thickness of two or more integrant particles; and the decrement, whether parallel to the edges or angles, consists not of the abstraction of one row of particles, but of two or more. Hauy denotes these decrements by fractions, in which the numerator indicates the number of rows of particles which constitutes the decrement, and the denominator represents the thickness of the laminæ. Thus $\frac{2}{3}$ denotes laminæ of the thickness of three integrant particles, decreasing by two rows of particles.

An example of the first law of decrement, or of decrement on the edges, has been given above in the conversion of the cubic nucleus to a rhomboidal dodecahedron. In that example the decrement consisted of one row of particles, and it took place on all the edges. But these decrements may be more rapid: instead of one, they may consist of two, three, four, or more rows; and instead of taking place on all the edges, they may be confined to one or two of them, while no decrement at all takes place on the others. Each of these different modifications must produce a different secondary crystal. Besides this, the laminæ may cease to be added before they have reached their smallest possible size; the consequence of which must be a different secondary form. Thus, in the example given above, if the superposition of laminæ had ceased before the pyramids were completed, the crystal would have consisted of 18 faces; 6 squares parallel to the faces of the primitive nucleus, and 12 hexahedrons parallel to the faces of the secondary dodecahedron. This is the figure of the barat of lime and magnesia found at Luneburg.

The second law in which the decrement is on the angles, or parallel to the diagonals of the faces of the primitive nucleus, will be understood from the following example: Let it be proposed to construct around the cube ABGF (fig. 11.), considered as a nucleus, a secondary solid, in which the laminæ of superposition shall decrease on all sides by single rows of cubes, but in a direction parallel to the diagonals. Let ABCD (fig. 12), the superior base of the nucleus, be divided into 81 squares, representing the faces of the small cubes of which it is composed. Fig. 13 represents the superior surface of the first lamina of superposition; which must be placed above ABCD (fig. 12) in such a manner, that the points *a b c d* (fig. 13) answer to the points *a b c d* (fig. 12). By this disposition the squares A*a*, B*b*, C*c*, D*d* (fig. 12), which compose the four outermost rows of squares parallel to the diagonals AC, BC, remain uncovered. It is evident also, that the borders QV, ON, IL, GF (fig. 13), project by one range beyond the borders AB, AD, CD, BC (fig. 13); which is necessary, that the nucleus may be enveloped towards these edges: for if this were not the case, re-entering angles would be formed towards the parts AB, BC, CD, DA, of the crystal; which angles appear to be excluded by the laws which determine the formation of simple crystals, or, which comes to the same thing, no such angles are ever observed in any crystal. The solid must increase, then, in those parts to which the decrement does not extend. But as this decrement is alone sufficient to determine the form of the secondary crystal, we may set aside all the other variations which intervene only in a subsidiary manner; except when it is wished, as in the present case, to construct artificially a solid representation of a crystal, and to exhibit all the details which relate to its structure.

The superior face of the second lamina will be AGLK (fig. 14.). It must be placed so that the points *a*, *b*, *c*, *d*, correspond to the points *a*, *b*, *c*, *d* (fig. 13); which will leave uncovered a second row of cubes at each angle, parallel to the diagonals AC and BD. The solid still increases towards the sides. The large faces of the laminæ of superposition, which in fig. 13 were octagons, in fig. 14 arrive at the form of a square; and when they pass that term they decrease on all sides; so that the next lamina has for its superior face the square RMLS (fig. 15) less by one range in every direction than the preceding lamina (fig. 14). This square must be placed so that the points *e*, *f*, *g*, *h* (fig. 15), correspond to the points *e*, *f*, *g*, *h* (fig. 14). Figures 16, 17, 18, and 19, represent the four laminæ which ought to rise successively above the preceding; the manner of placing them being pointed out by corresponding letters, as was done with respect to the first three laminæ. The last lamina *z* (fig. 20) is a single cube, which ought to be placed upon the square *z* (fig. 19).

The laminæ of superposition, thus applied upon the side ABCD (fig. 12), evidently produce four faces, which correspond to the points A, B, C, D, and form a pyramid. These faces, having been formed by laminæ which began by increasing, and afterwards decreased, must be quadrilaterals of the figure represented in fig. 21; in which the inferior angle C is the same point with the angle C of the nucleus (figs. 11 and 12,) and the diagonal LQ represents LQ of the lamina AGLK (fig 13). And as the number of laminæ composing the triangle LQC (fig. 21), is much smaller than that of the laminæ forming the triangle ZLQ, it is evident that the latter triangle will have a much greater height than the former.

The surface, then, of the secondary crystal thus produced, must evidently consist of 24 quadrilaterals, for pyramids are raised on the other 5 sides of the primary cube exactly in the same manner, disposed three and three around each solid angle of the nucleus. But in consequence of the decrement by one range, the three quadrilaterals which belong to each solid angle, as C

(fig 11.), will be in the same plane, and will form an equilateral triangle ZIN (fig. 22.). The 24 quadrilaterals then will produce 8 equilateral triangles; and consequently the secondary crystal will be a regular octahedron. This is the structure of the octahedral sulphuret of lead, and of muriat of soda.

The third law is occasioned by the abstraction of double, triple, &c. particles. Fig. 23 exhibits an instance of the subtractions in question: and the moleculæ which compose the range represented by that figure are assorted in such a manner as if of two there were formed only one; so that we need only to conceive the crystal composed of parallelopipedons having their bases equal to the small rectangles *a b c d, e d f g h i*, &c. to reduce this case under that of the common decrements on the angles.

This particular decrement, as well as the fourth law, which requires no further explanation, is uncommon. Indeed Hauy has met with mixed decrements only in some metallic crystals.

These different laws of decrement account for all the different forms of secondary crystals. But in order to see the vast number of secondary forms which may result from them, it is necessary to attend to the different modifications which result from their acting separately or together. These modifications may be reduced to seven.

1. The decrements take place sometimes on all the edges, or all the angels, at once.

2. Sometimes only on certain edges, or certain angles.

3. Sometimes they are uniform, and consist of one, two, or more rows.

4. Sometimes they vary from one edge to the other, or from one angle to another.

5. Sometimes decrements on the edges and angles take place at the same time.

6. Sometimes the same edge or angle is subjected successively to different laws of decrement.

7. Sometimes the secondary crystal has faces parallel to those of the primitive nucleus, from the superposition of laminæ not going beyond a certain extent.

Hence Mr. Hauy has divided secondary forms into two kinds, namely, simple and compound. Simple secondary crystals are those which result from a single law of decrement, and which entirely conceal the primitive nucleus. Compound secondary crystals are those which result from several laws of decrement at once; or from a single law which has not reached its limit, and which of course has left in the secondary crystal faces parallel to those of the primitive nucleus.

"If amidst this diversity of laws (observes Mr. Hauy) sometimes united by combinations more or less complex, the number of ranges subtracted was itself extremely variable; for example, were these decrements by 12, 20, 30, or 40 ranges, or more, as might absolutely be possible; the multitude of the forms which might exist in each kind of mineral would be immense, and exceed what could be imagined. But the power which effects the subtractions seems to have a very limited action. These subtractions, for the most part, take place by one or two ranges of molecules. I have found none which exceed four ranges, except in a variety of calcareous spar forming part of the collection of C. Gillet Laumont, the structure of which depends on a decrement by six ranges; so that if there exist laws which exceed the decrements by four ranges, there is reason to believe they rarely take place in nature. Yet notwithstanding these narrow limits by which the laws of crystallization are circumscribed, I have found, by confining myself to two of the simplest laws, viz. those which produce subtractions by one or two ranges, that calcareous spar is susceptible of 2044 different forms, a number which exceeds more than 50 times that of the forms already known: and if we admit into the combination decrements by three or four ranges, calculation will give 8,388,604 possible forms in regard to the same substance. This number may still be very much augmented in consequence of decrements either mixed or intermediary.

In the crystallization of metals, of salts, and other substances, soluble in caloric alone, as well as those soluble in water by the aid of caloric, the latter substance is given out in abundance (as in the freezing, or more properly, crystallization of water): hence the temperature of large masses of hot saline solutions diminishes at last very slowly during the increase of the crystals which have begun to form in them.

CRYSTALLINE-HUMOUR. See Optics.

CUBÆA, a genus of the decandria monogynia class and order. The calyx is turbinate, five-parted, unequal, permanent; petals five, unequal; filaments villose, three shorter; germ pedicelled; legume villose, six or seven-seeded. There are two species.

CUBE, a regular or solid body, consisting of six equal sides or fases, which are squares.

It is also called a hexahedron, because of its six sides, and is the second of the five Platonic or regular bodies.

The cube is supposed to be generated by the motion of a square plane, along a line equal and perpendicular to one of its sides.

To describe a rete, or net, for forming a cube, or with which it may be covered.—Describe six squares as in figure 27, upon card, paper, pasteboard, or the like, of the size of the faces of the proposed cube; and put it half through by the lines AB, CD, EF, AC, BD; then fold up the several squares till their edges meet, and so form the cube, or a covering over one, as in the figure annexed. See Pl. XXXIX. Miscel. fig. 27.

To determine the surface and solidity of a cube.—Multiply one side by itself, which will give one square or face: then this multiplied by 6, the number of faces, will give the whole surface. Also multiply one side by itself and that product again by the side, and that will be the solid content.

Cubes, or Cubic Numbers, are formed by multiplying any numbers by themselves and their products by the numbers again.

So the cubes of 1, 2, 3, 4, 5, 6, &c.
are 1, 8, 27, 64, 125, 216, &c.

The third differences of the cubes of the natural numbers are all equal to each other, being the constant number 6. For, let m, n, p, be any three adjacent cubes in the natural series as above, that is, whose roots m, n, p, have the common differences 1; then, because

$n = m + 1$, therefore $n^3 = m^3 + 3m^2 + 3m + 1$.
$p = n + 1$, therefore $p^3 = n^3 + 3n^2 + 3n + 1$;

so that the difference between the 1st and 2d, and between the 2d and 3d cubes, are

$n^3 - m^3 = 3m^2 + 3m + 1$,
$p^3 - n^3 = 3n^2 + 3n + 1$, } the 1st differences;

and the difference of these differences, is

$3 \cdot \overline{n^2 - m^2} + 3 \cdot \overline{n - m} = 3 \cdot \overline{n + m + 1} = 6 \cdot \overline{m + 1}$, the 2d difference.

In like manner the next 2d difference is $6 \cdot \overline{n + 1}$: hence the difference of these two 2d differences is $6 \cdot \overline{n - m} = 6$, which is therefore the constant 3d difference of all the series of cubes. And hence that series of cubes will be formed by addition only, viz. adding always the 3d difference 6 to find the column or series of 2d differences, then these added always for the 1st differences, and lastly, these always added for the cubes themselves, as below:

3d Difs.	2 Difs.	1st Difs.	Cubes.
6	6	1	0
6	12	7	1
6	18	19	8
6	24	37	27
6	30	61	64
6	36	91	125
6	42	127	216
6	48	169	343

Peletarius, among various speculations concerning square and cubic numbers, shows that the continual sums of the cubic numbers, whose roots are 1, 2, 3, &c. form the series of squares whose roots are 1, 3, 6, 10, 15, 21, &c.

Thus,
$1 = 1 = 1^2$
$1 + 8 = 9 = 3^2$
$1 + 8 + 27 = 36 = 6^2$
$1 + 8 + 27 + 64 = 100 = 10^2$, &c.

Or, in general, $1^3 + 2^2 + 3^3 + 4^3$, &c. to n^3
$= \overline{1 + 2 + 3 + 4 \cdots n}^2 = \frac{1}{2}n \cdot n + 1$.

It is also a curious property, that any number, and the cube of it, being divided by 6, leave the same remainder; the series of remainders being 0, 1, 2, 3, 4, 5, continually repeated. Or that the differences between the numbers and their cubes, divided by 6, leave always 0 remaining; and the quotients, with their successive differences, form the several orders of figurate numbers. Thus.

Num.	Cubes.	Difs.	Quot.	1 Dif.	2 Dif.
1	1	0	0	0	0
2	8	6	1	1	1
3	27	24	4	3	2
4	64	60	10	6	3
5	125	120	20	10	4
6	216	210	35	15	5
7	343	336	56	21	6

CUBE, *duplication of*, is the finding the side of a cube that shall double in solidity a given cube, which is a celebrated problem, much discussed by ancient geometricians. It was first proposed by the oracle of Apollo at Delphos, which declared that the plague, then raging at Athens, should cease when Apollo's altar, a cube, was doubled. Upon this the mathematicians applied themselves seriously to seek the duplicature of the cube; hence it is called the Delian problem. It cannot, however, be effected geometrically, as it requires the solution of a cubic equation, or requires the finding of two mean proportionals, viz. between the side of the given cube and the double of the same, the first of which two mean proportions is the side of the double cube, as was first observed by Hippocrates of Chios. For, let a be the side of the given cube, and z the side of the double cube sought; then it is $z^3 = 2a^3$, or $a^2 : z^2 :: z : 2a$; so that, if a and z be the first and 2d terms of a set of continued proportionals, then $a^2 : z^2$ is the ratio of the square of the first to the square of the 2d, which, it is known, is the same as the ratio of the first term to the 3d, or of the 2d to the 4th, that is, of z to $2a$; therefore z being the 2d term, $2a$ will be the 4th. So that z, the side of the cube sought, is the 2d of four terms in continued proportion, the first and 4th being a and $2a$, that is, the side of the double cube is the first of two mean proportionals between a and $2a$. The thing has been frequently done mechanically by Archimedes, Eutochius, Pappus, &c.

CUBE, or *Cubic number*, in arithmetic, that which is produced by the multiplication of a square number by its root: thus, 64 is a cube number, and rises by multiplying 16, the square of 4, by the root 4.

CUBE, or *Cubic quantity*, in algebra, the third power in a series of geometrical proportionals continued; as a is the root, aa the square, and aaa the cube. All cubic numbers may be ranged into the form of cubes; as 8 or 27, whose sides are 2 and 3, and their bases 4 and 9; whence it appears, that every true cubic number, produced from a binomial root, consits of these parts, viz. The cubes of the greater and lesser parts of the root, and of three times the square of the greater part multiplied by the lesser, and of three times the square of the lesser multiplied by the greater, as,

$$\begin{array}{r} aa + 2ab + bb \\ a + b \\ \hline aaa + 2aab + abb \\ \quad aab + 2abb + bbb \\ \hline aaa + 3aab + 3abb + bbb \end{array}$$

From hence it is easy to understand both the composition of any cubic number, and the reason of the method for extracting the cube root out of any number given. See the following article.

CUBE *root of any number, or quantity*, such a number, or quantity, which, if multiplied into itself, and then, again, the product thence arising, by that number or quantity, being the cube root, this last product shall be equal to the number or quantity whereof it is the cube root: as 2 is the cube root of 8, because two times 2 are 4, and two times 4 are 8; and $a + b$ is the cube root of $a^3 + 3a^2b + 3ab^2 + b^3$.

Every cube number has three roots, one real root, and two imaginary ones; as the cube number 8 has one real root 2, and two imaginary roots, viz. $\sqrt{-3} - 1$, and $\sqrt{-3} + 1$; and generally if a be the real root of any cube

number, one of the imaginary roots of that number will be $\frac{a+\sqrt{-3aa}}{2}$, and the other $\frac{a-\sqrt{-3aa}}{2}$. See Algebra.

CUBEBS, cubeba of the shops, in the materia medica, a small dried fruit, resembling a grain of pepper, but often somewhat longer, brought into Europe from the island of Java. See Materia Medica.

CUBIC, or Cubical, Equation, in algebra, one whose highest power consists of three dimensions, as $x^3 = a^3 - b^3$, or $x^3 + rxx = p^6$, &c.

CUBIT, in the mensuration of the ancients, a long measure, equal to the length of a man's arm, from the elbow to the tip of the fingers. Dr. Arbuthnot makes the English cubit equal to 18 inches; the Roman cubit equal to one foot, 5,406 inches; and the cubit of the scripture equal to one foot, 9,888 inches.

CUBITÆUS. See Anatomy.

CUBITUS, in anatomy, a bone of the arm, reaching from the elbow to the wrist, otherwise called the ulna.

CUCKING-stool, anciently called tumbrel, an engine invented for the punishment of scolds and unquiet women, by ducking them. This instrument was a sort of chair, placed at the end of a plank, in which the offender was placed, and so ducked: it was formerly made use of to punish bakers and brewers, upon transgressing the laws made in relation to their several trades; for upon offending in this respect, they were ducked, or plunged in some stinking muddy pond, by means of this chair.

CUCUBALUS, berry-bearing chickweed, a genus of the trigynia order in the decandria class of plants, and in the natural method ranking under the 22d order, caryophylei. The calyx is inflated, the petals 5, unguiculated without; a nectariferous corona at the throat; the capsule is trilocular. There are 17 species; the most remarkable of which are,

1. The behen, Swedish lychnis, or gumsepungar, a native of several parts of Europe. The empalement of its flower is curiously wrought like a network, and is of a purplish colour. The leaves have somewhat of the flavour of peas, and proved of great use to the inhabitants of Minorca in 1685, when a swarm of locusts had destroyed the harvest. The Gothlanders apply the leaves to erysipelatous eruptions. Horses, cows, sheep, and goats, eat this plant.

2. The catholicus, or night-flowering lychnis, grows naturally in Spain and Italy. It is a perennial plant, rising with an upright branching stalk a foot and a half high, with very narrow leaves placed opposite. The flowers stand upon long naked footstalks, each supporting three or four flowers which have long tubes with striped empalements: the petals are large, deeply divided at top, and of a pale-blueish colour. The flowers are closed all the day; but when the sun leaves them, they expand, and then emit a very agreeable scent. It may be propagated by seeds sown in the spring on a bed of light earth, and will flower the following year.

3. The otites, or catch-fly, is a native of Britain and other European countries. It has a thick, fleshy, perennial root, which strikes into the ground, whence rises a jointed stalk three or four feet high. At the joints there exudes a viscous clammy juice, that sticks to the fingers when handled; and the small insects which settle upon those parts of the stalks are so fastened that they cannot get off. The flowers are small, and of a greenish colour.

CUCUJUS, a genus of insects of the coleoptera order: antennæ filiform; feelers four, equal, the last joint truncate and thicker; lip short, bifid; the divisions linear and distant; body depressed. There are 11 species belonging to this genus.

CUCULLANUS, a genus of worms of the order intestina: body sharp, pointed behind and obtuse before; mouth orbicular, with a striated hood. They are most of them viviparous. There are eight species, which take their names from the animal in which they are found. Thus, the cucullanus talpæ inhabits the common mole, is gregarious, inclosed in a membrane, spirally twisted, white, and found in the fat about the peritoneum.

CUCULLARIS, see Anatomy.

CUCULUS, the cuckow, in ornithology, a genus belonging to the order of picæ; the essential characters of which are: the bill is smooth, and more or less bending; the nostrils are bounded by a small rim; the tongue is short and pointed; the feet and toes formed for climbing. See Pl. XXXIX. N. II. fig. 153. There are 46 species. The most remarkable are:

1. The canorus, or common cuckow, weighs about five ounces, and is in length 14 inches, in breadth 25. The bill is black, and about two-thirds of an inch in length. The head, hind part of the neck, coverts of the wings and rump, are of a dove-colour, darker on the head and paler on the rump. The legs are short, and the toes disposed two backwards and two forwards, like those of the woodpecker, though it is never observed to run up the sides of trees. The female differs in some respects.

This bird appears in England early in the spring, and makes the shortest stay there of any bird of passage. It is directed thither by that constitution of the air which causes the fig-tree to put forth its fruit; though it has been supposed that some of these birds do not quit that island during the winter, but that they seek shelter in hollow trees, and lie torpid, unless animated by unusually warm weather. Mr. Pennant gives two instances of their being heard in February; one in 1771, in the end of that month; the other in 1769, on the fourth day; but after that they were heard no more, being probably chilled into torpidity. There is a remarkable coincidence between the song of these birds, and the mackarels continuing in full roe; that is, from about the middle of April to the latter part of June. The cuckow is silent for some time after his arrival. His note is so uniform, that his name in all languages seems to have been derived from it; and in all countries it is used in the same reproachful sense.

On the natural history of this singular bird, we have a very curious paper by Dr. Jenner, published in the Philosophical Transactions for 1788, part II. art. 14. The first appearance of cuckows in the county of Gloucester is about the middle of April. The song of the male, which is well known, soon proclaims its arriv-

al. The song of the female (if the peculiar notes of which it is composed may be so called) is widely different, and has been so little attended to, that perhaps few are acquainted with it: the cry of the dabchick bears some resemblance to it.

Unlike the generality of birds, cuckows do not pair. When a female appears on the wing, she is often attended by two or three males. From the time of her appearance till after the middle of summer, the nests of the birds selected to receive her egg are to be found in great abundance; but, like the other migrating birds, she does not begin to lay till some weeks after her arrival.

It is on all hands allowed that the cuckow does not hatch its own eggs; for which different reasons have been given, as will be afterwards noticed. The hedge-sparrow, the water-wagtail, the titlark, the redbreast, the yellow-hammer, the green-linnet, or the winchat, is generally the nurse of the young cuckow: but Buffon enumerates 20 sorts of nests at least in which they have deposited their eggs. It may be supposed that the female cuckow lays her egg in the absence of the bird in whose nest she intends to deposit it; as it has been known that on sight of one of these, a redbreast and its mate jointly attacked her on approaching the nest, putting her to flight; and so effectually drove her away, that she did not dare to return. Among the birds above-mentioned, it generally, according to Dr. Jenner's observations, selects the first three, but shows a much greater partiality to the hedge-sparrow. This last commonly takes up four or five days in laying her eggs. During this time (generally after she has laid one or two) the cuckow contrives to deposit her egg among the rest, leaving the future care of it entirely to the hedge-sparrow. This intrusion often occasions some discomposure: for the old hedge-sparrow at intervals, whilst she is sitting, not unfrequently throws out some of her own eggs, and sometimes injures them in such a way that they become addle; so that it more frequently happens that only two or three hedge-sparrow's eggs are hatched with the cuckow's than otherwise. But whether this is the case or not, she sits the same length of time as if no foreign egg had been introduced, the cuckow's egg requiring no longer incubation than her own.

When the hedge-sparrow has sat her usual time, and disengaged the young cuckow and some of her own offspring from the shell, her own young ones, and any of her eggs that remain unhatched, are soon turned out, the young cuckow remaining possessor of the nest, and the sole object of her future care. The young birds are not previously killed, nor are the eggs demolished; but all are left to perish together, either entangled about the bush which contains the nest, or lying on the ground under it.

"The early fate of the young hedge-sparrows (Dr. Jenner observes) is a circumstance that has been noticed by others, but attributed to wrong causes. A variety of conjectures have been formed upon it. Some have supposed the parent cuckow the author of their destruction; while others, as erroneously, have pronounced them smothered by the disproportionate size of their fellow-nestling. Now the cuckow's egg being not much larger than the hedge-sparrow's, it necessarily follows, that at first there can be no difference in the size of the birds just burst from the shell. Of the fallacy of the former assertion also I was some years ago convinced by having found that many cuckow's eggs were hatched in the nests of other birds after the old cuckow had disappeared; and by seeing the same fate then attend the nestling sparrows as during the appearance of old cuckows in this country." But before he enters on the facts relating to the death of the young sparrows, our author proceeds to state various examples of the incubation of the egg, and the rearing of the young cuckow; a point which had been controverted by the hon. Daines Barrington, and disbelieved by others. For these, however, on account of their great length, we refer the reader to the original paper.

It appears a little extraordinary that two cuckows' eggs should ever be deposited in the same nest, as the young one produced from one of them must inevitably perish; yet two instances of this kind fell under our author's observation, one of which he thus relates: "June 27, 1787. Two cuckows and a hedge-sparrow were hatched in the same nest this morning; one hedge-sparrow's egg remained unhatched. In a few hours after, a contest began between the cuckows for the possession of the nest, which continued undetermined till the next afternoon; when one of them, which was somewhat superior in size, turned out the other, together with the young hedge-sparrow and the unhatched egg. This contest was very remarkable. The combatants alternately appeared to have the advantage, as each carried the other several times nearly to the top of the nest, and then sunk down again, oppressed by the weight of its burden; till at length, after various efforts, the strongest prevailed, and was afterwards brought up by the hedge-sparrows."

But the principal circumstance that has agitated the mind of the naturalist respecting the cuckow is, why, like other birds, it should not build a nest, incubate its eggs, and rear its own young? There is no apparent reason, Dr. Jenner thinks, why this bird, in common with others, should not perform all these several offices; for it is in every respect perfectly formed for collecting materials, and building a nest. Neither its external shape nor internal structure prevents it from incubation; nor is it by any means incapacitated from bringing food to its young. It would be needless to enumerate the various opinions of authors on this subject from Aristotle to the present time. Those of the ancients appear to be either visionary or erroneous; and the attempts of the moderns towards its investigation have been confined within very narrow limits: for they have gone but little further in their researches than to examine the constitution and structure of the bird; and having found it possessed of a capacious stomach, with a thin external covering, concluded that the pressure upon this part, in a sitting posture, prevented incubation. They have not considered that many of the birds which incubate have stomachs analogous to those of cuckows. The stomach of the owl, for example, is proportionably capacious, and is almost as thinly covered with external integuments. Nor have they considered that the stomachs of nestlings are always much distended with food; and that this very part, during the whole time of their confinement to the nest, supports in a great degree the weight of the whole body: whereas, in a sitting bird, it is not nearly so much

pressed upon; for the breast in that case fills up chiefly the cavity of the nest; for which purpose, from its natural convexity, it is admirably well fitted. These observations sufficiently show that the cuckow is not rendered incapable of sitting through any peculiarity either in the situation or formation of the stomach.

In considering to what causes may be attributed the singularities of the cuckow, Dr. Jenner suggests the following as the most probable: "The short residence this bird is allowed to make in the country where it is destined to propagate its species; and the call that nature has upon it, during that short residence, to produce a numerous progeny." The cuckow's first appearance here is about the middle of April, commonly on the 17th. Its egg is not ready for incubation till some weeks after its arrival, seldom before the middle of May. A fortnight is taken up by the sitting-bird in hatching the egg. The young bird generally continues three weeks in the nest before it flies, and the foster parents feed it more than five weeks after this period; so that if a cuckow should be ready with an egg much sooner than the time pointed out, not a single nestling, even one of the earliest, would be fit to provide for itself before its parent would be instinctively directed to seek a new residence, and be thus compelled to abandon its young one; for old cuckows take their final leave of this country the first week in July.

There seems to be no precise time fixed for the departure of young cuckows. Our author believes they go off in succession, probably as soon as they are capable of taking care of themselves; for although they stay here till they become nearly equal in size and growth of plumage to the old cuckow, yet in this very state the fostering care of the hedge-sparrow is not withdrawn from them.

It is supposed that there are more male cuckows than females; since two are often seen in dispute where a third has been in sight; which, no doubt, was of the opposite sex. Mr. Pennant observed, that five male birds were caught in a trap in one season; and Mr. Latham says, that "out of at least half a dozen that I have attended to, my chance has never directed me to a female; and it is to be wished that future observers may determine whether our observations have risen only in chance, or are founded on general circumstances." He believes that the male birds are more liable to be shot, their note directing the gunner where to take aim, while the female is secured by her silence.

Cuckows may be, and often are, brought up tame, so as to become familiar. They will eat in this state bread and milk, fruit, insects, eggs, and flesh either cooked or raw; but in a state of nature chiefly live on caterpillars of the smooth kind. Some have fed on vegetable matter, beetles, and small stones. When fat, they are said to be as good eating as a land-rail. The French and Italians eat them to this day. The ancient Romans admired them greatly as food; and Pliny says that there is no bird which can be compared to them for delicacy.

In migrating, the major part of these birds are supposed to go into Africa; since they are observed to visit the island of Malta twice in a year in their passage backwards and forwards, as is supposed, to that part of the world. The cuckow is well known also at Aleppo. To the north, it is said to be common in Sweden; but not to appear so early by a month as with us. Russia is not destitute of this bird; and Mr. Latham has seen a specimen brought from Kamtschatka, now in the possession of sir Joseph Banks.

2. The indicator, or honey-guide, is a native of America. The following description is given of it by Dr. Sparrman, in the Philosophical Transactions for 1777. "This curious species of cuckow is found at a considerable distance from the Cape of Good Hope, in the interior parts of Africa, being entirely unknown at that settlement. The first place I heard of it was in a wood called the Groot-Vaader's Bosch, the Grandfather's Wood, situated in a desert near the river which the Hottentots call T'kaut'kai. The Dutch settlers thereabout have given this bird the name of honiguyzer, or honey-guide, from its quality of discovering wild honey to travellers. Its colour has nothing striking or beautiful: its size is smaller than that of our cuckow in Europe; but in return, the instinct which prompts it to seek its food in a singular manner is truly admirable. Not only the Dutch and Hottentots, but likewise a species of quadruped named ratel (probably a new species of badger), are frequently conducted to wild bee-hives by this bird, which, as it were, pilots them to the very spot. The honey being its favourite food, its own interest prompts it to be instrumental in robbing the hive, as some scraps are commonly left for its support. The morning and evening are its times of feeding, and it is then heard calling in a shrill tone, *cherr, cherr*, which the honey-hunters carefully attend to as the summons to the chace. From time to time they answer with a soft whistle, which the bird hearing always continues its note. As soon as they are in sight of each other, the bird gradually flutters towards the place where the hive is situated, continually repeating its former call of *cherr, cherr;* nay, if it should happen to have gained a considerable way before the men (who may easily be hindered in the pursuit by bushes, rivers, or the like), it returns to them again, and redoubles its note, as if to reproach them with their inactivity. At last the bird is observed to hover for a few moments over a certain spot; and then silently retiring to a neighbouring bush or resting-place, the hunters are sure of finding the bees' nest in that identical spot; whether it be in a tree or in the crevice of a rock, or (as is most commonly the case) in the earth. Whilst the hunters are busy in taking the honey, the bird is seen looking on attentively to what is going forward, and waiting for its share of the spoil. The bee-hunters never fail to leave a small portion for their conductor; but commonly take care not to leave so much as would satisfy his hunger. The bird's appetite being whetted by this parsimony, he is obliged to commit a second treason, by discovering another bees' nest, in hopes of a better salary. It is further observed, that the nearer the bird approaches the hidden hive, the more frequently it repeats its call, and seems the more impatient. I have had frequent opportunities of seeing this bird, and have been witness to the destruction of several republics of bees by means of its treachery. I had, however, but two opportunities of shooting it, which I did to the great indignation of my Hottentots. It is about seven inches

in length, and is of a rusty-brown colour on the back, with a white breast and belly." A nest which was shown to Dr. Sparrman for that of this bird, was composed of slender filaments of bark, woven together in the form of a bottle; the neck and opening hung downwards, and a string, in an arched shape, was suspended across the opening, fastened by the two ends, perhaps for the bird to perch on.

3. The capensis or Cape cuckow (Buffon) is a trifle smaller than the common. It inhabits the Cape of Good Hope; and is most likely the same bird which is called edolio, from its pronouncing that word frequently in a low melancholy tone. Voyagers also mention another cuckow which is common to Loango in Africa. It is also larger, but of the same colour, and repeats the word *cuckow* like that bird, but in a different inflection of voice. It is said that the male and female together go through the whole eight notes of the gamut; the male, beginning by itself, sounds the first three, after which he is accompanied by the female through the rest of the octave.

4. The honoratus, or sacred cuckow, is somewhat less than that of England. This species inhabits Malabar, where the natives hold it sacred. It feeds on reptiles, which perhaps may be such as are the most noxious: if so, this seeming superstition may have arisen from a more reasonable foundation than many others of the like sort.

5. The vetula is rather larger than a blackbird. This species inabits Jamaica, where it is frequent in the woods and hedges all the year round. It feeds on seeds, small worms, and caterpillars, and is very tame. This bird has the name *tacco* from its cry, which is like that word; the first syllable of this is pronounced hardly, the other following in a full octave lower than the first. It has also another cry like *qua, qua, qua*, but that only when alarmed by an enemy. Besides insects, it will also eat lizards, small snakes, frogs, young rats, and sometimes even small birds. The snakes they swallow head foremost, letting the tail hang out of the mouth till the fore parts are digested. This bird, it is most likely, might be easily tamed, as it is so gentle as to suffer the negro children to catch it with their hands. Its gait is that of leaping like a magpie, being frequently seen on the ground; and its flight but short, chiefly from bush to bush. At the time when other birds breed, they likewise retire into the woods, but their nests have never yet been found; from which we should be inclined to think that they were indebted to other birds for the rearing of their young, in the manner of the common cuckow. It has the name of rain-bird, as it is said to make the greatest noise before rain. It is common all the year at Jamaica. In another species or variety, common in Jamaica, the feathers on the throat appear like a downy beard, whence probably the name of old-man rain-bird, given it there, and by Ray, Sloane, and others.

6. The cayanus, or Cayenne cuckow, is the size of a blackbird. This inhabits Cayenne, where it goes by the name of the piaye or devil. The natives give it that name, as a bird of ill-omen. The flesh they will not touch; and indeed not without reason, as it is very bad and lean. It is a very tame species, suffering itself to be almost touched by the hand before it offers to escape. Its flight is almost like that of a king's-fisher, and it frequents the borders of rivers on the low branches, feeding on insects, and often wagging its tail on changing place.

CUCUMIS, the cucumber, a genus of the syngenesia order, in the monœcia class of plants, and in the natural method ranking under the 34th order, cucurbitaceæ. The male calyx is quinquedentated, the corolla quinquepartite the filaments three. The female calyx is also quinquedentated, the corolla quinquepartite, the pistil trifid; the sides of the apple sharp-pointed. In this genus Linnæus includes also the melon.

There are 13 species, of which the following are the most remarkable.

1. The sativa, or common cucumber, has roots composed of long, slender, white fibres; long slender stalks, very branchy at their joints, trailing on the ground, or climbing by their claspers, adorned at every joint by large angular leaves on long erect footstalks, with numerous and monopetalous bell-shaped flowers of a yellow colour, succeeded by oblong rough fruit. The varieties of this kind are, 1. The common rough green prickly cucumber; a middle sized fruit, about six or seven inches long, having a dark-green rough rind, closely set with very small prickles: the plant is of the hardiest sort, but does not show its fruit early. 2. The short green prickly cucumber is about three or four inches long, the rind rather smooth, and set with small prickles. It is valuable chiefly for being one of the earliest and hardiest sorts. 3. The long green prickly cucumber, grows from six to nine inches in length, and is rather thinly set with prickles: and as there are an early and a late cucumber, it is considerably the best variety for the main crops, both in the frames and hand-glass, as well as in the open ground for picklers. Of this there is another variety with white fruit. 4. The early green cluster cucumber is a shortish fruit, remarkable for growing in clusters, and appearing early. 5. The long smooth green Turkey cucumber is a smooth green rinded-fruit, growing from 10 to 15 inches in length, without prickles. The plants are strong growers, with very large leaves. 6. The long smooth white Turkey cucumber, is a smooth-rinded fruit, from 10 to 15 inches long without prickles. 7. The large smooth green Roman cucumber is a very large and long smooth green fruit, produced from a strong-growing plant. 8. The long white prickly Dutch cucumber is a white fruit, eight or ten inches long, set with small black prickles.

2. The chata, or hairy cucumber. According to Mr. Hasselquist this grows in the fertile earth near Cairo, after the inundation of the Nile, and not in any other place in Egypt, nor does it grow in any other soil. The fruit is a little watery; the flesh almost of the same substance with the melons; it tastes somewhat sweet and cool, but is far from being so cool as the water-melons. This the grandees and Europeans in Egypt eat as the most pleasant fruit they find, and that from which they have the least to apprehend. It is the most excellent fruit of this tribe, of any yet known.

3. The melo, or melon. The varieties of this species are almost endless. The most esteemed are, 1. The canteloupe, a small melon good for early culture. 2. The Roman. 3. The galloway, or Portugal melon. The

grand mistake in the culture of melons is, planting them early; for without sun to ripen them well, melons are not worth the trouble of eating.

Cucumbers in this country are raised at three different seasons of the year: 1. on hot-beds, for early fruit; 2. on the common ground, for the middle crop: 3. which is for a late crop or to pickle. The cucumbers which are ripe before April are unwholsome, being raised wholly by the heat of the dung without the assistance of the sun. Those raised in April are good.

Besides the above-mentioned species, which are proper for the table, this genus affords also two articles for the materia medica. 1. The elaterium of the shops, is the inspissated fæcula of the juice of a kind of wild cucumber, called also the elatinum or ass's cucumber. It comes to this country from Spain and the southern parts of France, where the plant is very common. It is brought to us in small flat whitish lumps or cakes that are dry, and break easily between the fingers. It is of an acrid, bitter and nauseous taste, and has a strong offensive smell when newly made: but these, as well as its other qualities, it loses after being kept some time. Elaterium is a violent purge and vomit, and is now very seldom used. The plant is commonly called spirting cucumber, from its casting out its seeds with great violence, together with the vicid juice in which they are lodged, if touched when ripe: from this circumstance it has obtained the appellation of *noli me tangere*, or *touch-me-not*. 2. The colocynthis, colocynth, coloquintida, or bitter apple of the shops, is brought to us from Aleppo and the island of Crete. The leaves of the plant are large, placed alternate, almost round, and stand upon footstalks four inches long. The flowers are white; and are succeeded by a fruit resembling the gourd, of the size of a large apple, and which is yellow when ripe. The shelly or husky outside incloses a bitter pulp interspersed with flattish seeds. If a hole is made in one of these ripe gourds, and a glass of rum poured in and suffered to remain 24 hours, it proves a powerful purgative. The pulp itself dried and powdered is commonly used as a purgative in this country, but is one of the most drastic, and if taken in a large dose, somewhat hazardous.

CUCURBIT, in chemistry, an earthen or glass vessel, so called from its resemblance to a gourd, arising gradually from a wide bottom, and terminating in a narrow neck.

CUCURBITA, the gourd and pompion, a genus of the syngenesia order, in the monœcia class of plants, and in the natural method ranking under the 34th order, cucurbitaceæ. The calyx of the male is quinquedentated. the corolla quinquefid, the filaments three: the calyx of the female is quinquedentated, the corolla quinquefid, the pistil quinquefid, the seeds of the apple with a tumid margin.

There are seven species, viz.

1. The lagenaria, or bottle-gourd, rises with thick trailing downy stalks, branching into many spreading runners. These extend along the ground sometimes 15 or 20 feet in length. The leaves are large; the flowers are large and white, succeeded by long incurvated whitish yellow fruit, attaining from about two to five or six feet in length, and from about nine to twenty-four inches in circumference, having a ligneous and durable shell.

2. The pepo or pompion, commonly called pumpkin, has strong trailing rough stalks, branching into numerous runners. These are much larger than the former, extending from ten to forty or fifty feet each way. They have yellow flowers. The flowers are succeeded by large, round, smooth fruit, of different forms and sizes; some as large as a peck, others as big as half a bushel measure; some considerably less, and others not exceeding the bulk of an orange, ripening to a yellow, and sometimes to a whitish colour. This species is the most hardy of any, as well as the most extensive in their growth. A single plant, if properly encouraged, will overspread 10 or 15 roods of ground, and produce a great number of fruit, which, when young, are generally a mixture between a deep blue and pale white, but change as they increase in bulk.

3. The verrucosa, or warted gourd, has trailing stalks very branchy, and running upon the ground 10 or 15 feet each way; large lobated leaves, and yellow flowers, succeeded by roundish, knobby, warted, white fruit, of a moderate size.

4. The melopepo, erect gourd, or squash, rises with an erect strong stalk several feet high, rarely sending forth side-runners, but becoming bushy upward. It is adorned with large lobated leaves; and the flowers are succeeded by depressed knotty fruit, both white and yellow, commonly of a moderate size.

5. The hispida.

6. The ovifera.

7. The citrullus, or water-melon, the fruit of which is often a foot or a foot and a half in diameter. It is much admired in hot climates for its refreshing coolness; but to an English palate it is always insipid.

Of all these species there are a great many varieties, and the fruit of every species is observed to be surprisingly apt to change its form.

All the species of gourds and pompions, with their respective varieties, are raised from seed sown annually in April or the beginning of May, either with or without the help of artificial heat. But the plants forwarded in a hotbed till about a month old, produce fruit a month or six weeks earlier on that account, and ripen proportionably sooner.

In England these plants are cultivated chiefly for curiosity; though, mixed with apples, their pulp makes excellent tarts. In the places where they are natives, they answer many important purposes. In both the Indies, bottle-gourds are very commonly cultivated and sold in the markets. They make the principal food of the common people, particularly in the warm months of June, July, and August. The Arabians call this kind of gourd *charrah*. It grows commonly on the mountains in their deserts. The natives boil and season it with vinegar; and sometimes, filling the shell with rice and meat, make a kind of pudding of it. The hard shell is used for holding water, and some of them are capacious enough to contain 22 gallons; these, however, are very uncommon. The fruit of the pompion constitutes a great part of the food of the common people during the hot months, in those places where it grows. If gathered when not much bigger than a hen or goose egg, and properly seasoned with

butter, &c. it makes a tolerable good sauce for butcher's meat, and is also used in soups. In England it is seldom used till grown to maturity. The third species is also used in America for culinary purposes. The fruit is gathered when about half-grown, boiled, and eaten as sauce to butcher's meat. The squashes are also treated in the same manner, and esteemed delicate eating.

CUDDY, in great ships, a place lying between the captain-lieutenant's cabin and the quarter-deck, under the poop. It is divided into partitions for the master and other officers.

CUI *ante divortium*, a writ that a woman divorced from her husband has to recover her lands and tenements, which, before her coverture, she held in fee simple, in tail, or for life, from a person to whom her husband had alienated them during the marriage, when it was not in her power to gainsay it.

CUI *in vita*, a writ of entry which a widow may have against him to whom her husband in his life-time alienated her lands or tenements, without her consent first had, and her lawfully joining therein.

CUIRASS, a piece of defensive armour, made of iron plate, well hammered, serving to cover the body from the neck to the girdle, both before and behind: whence,

CUIRASSIERS, cavalry armed with cuirasses, as most of the Germans formerly were.

CULDEES, in the church history, a sort of monkish priests, formerly inhabiting Scotland and Ireland. Being remarkable for the religious exercises of preaching and praying, they were called, by way of eminence, *cultores Dei;* whence is derived the word culdees. They made choice of one of their own fraternity to be their spiritual head, who was afterwards called the Scots bishop.

CULEUS, in Roman antiquity, the largest measure of capacity for things liquid, equal to 20 amphoræ, or 40 urnæ. It contained 143 gallons three pints, English wine measure, or 11,095 solid inches.

CULEX, the gnat, a genus of insects belonging to the order of diptera. The mouth is formed by a flexible sheath, inclosing bristles pointed like stings. The antennæ of the males are filiform; those of the females feathered. There are seven species. These insects, too well known by the severe punctures they inflict, and the itchings thence arising, afford a most interesting history. Before they turn to flying insects, they have been in some measure fishes, under two different forms. "You may observe in stagnate waters," says Barbut, "from the beginning of May till winter, small grubs with their heads downwards, and their hinder parts on the surface of the water; from which part arises sideways a kind of vent-hole, or small hollow tube like a funnel; and this is the organ of respiration. The head is armed with hooks that serve to seize on insects and bits of grass, on which it feeds. On the sides are placed four small fins, by the help of which the insect swims about, and dives to the bottom. These larvæ retain their form during a fortnight or three weeks, after which period they turn to chrysalids. All the parts of the winged insect are distinguishable through the outward robe that shrouds them. The chrysalids are rolled up into spirals. The situation and shape of the windpipe is then altered; it consists of two tubes near the head, which occupy the place of the stigmata, through these the winged insect is one day to breathe. These chrysalids, constantly on the surface of the water in order to draw breath, abstain now from eating; but upon the least motion are seen to unroll themselves, and plunge to the bottom, by means of little paddles situated at the hinder part. After three or four days of strict fasting, they pass to the state of a gnat. A moment before, water was its element; but now it becomes an aerial insect, he can no longer exist in it. He swells his head, and bursts his inclosure. The robe he lately wore turns to a ship, of which the insect is the mast and the sail. If at the instant when the gnat displays his wings there arises a breeze, it proves to him a dreadful hurricane; the water gets into the ship, and the insect, who is not yet loosened from it, sinks, and is lost. But in calm weather, the gnat forsakes his slough, dries himself, flies into the air, and seeks to pump the alimentary juice of leaves, or the blood of men and beasts. The sting which our naked eye discovers, is but a tube, containing five or six spicula of exquisite minuteness; some dentated at their extremity like the head of an arrow, others sharp-edged like razors. These spicula, introduced into the veins, act as pump-suckers, into which the blood ascends by reason of the smallness of the capillary tubes. The insect injects a small quantity of liquor into the wound, by which the blood becomes more fluid, and is seen through the microscope passing through those spicula. The animal swells, grows red, and does not quit his hold till it has gorged itself. The liquor it has injected causes by its irritation that disagreeable itching which we experience; and which may be removed by volatile alkali, or by scratching the part newly stung, and washing it with vinegar. Rubbing one's self at night with fullers' earth and water, lessens the pain and inflammation. Gnats perform the copulation in the air. The female deposits her eggs on the water, by the help of her moveable hinder part and her legs, placing them one by the side of another in the form of a little boat. This vessel, composed of two or three hundred eggs, swims on the water for two or three days, after which they are hatched. If a storm arises, the boats are sunk. Every month there is a fresh progeny of these insects. Were they not devoured by swallows, other birds, and by several carnivorous insects, the air would be darkened by them."

Gnats in this country, however troublesome they may be, do not make us feel them so severely as the musketo flies (culex pipiens) do in foreign parts. Both day and night they come into the houses; and when the people are gone to bed, they begin their disagreeable humming, approach always nearer to the bed, and at last suck up so much blood that they can hardly fly away. The bite causes blisters in people of a delicate constitution. When the weather has been cool for some days, the musketoes disappear; but where it changes again, and especially after rain, they gather frequently in such quantities about the houses, that their number is astonishing. In sultry evenings they accompany the cattle in great swarms from the woods to the houses or to town; and when they are driven before the houses, the gnats fly in wherever they can. In greatest heat of summer, they are so numerous in some places, that the air seems to be quite full of them, espe-

ally near swamps and stagnate waters, such as the river Morris in New-Jersey. The inhabitants therefore make a fire to expel these disagreeable guests by the smoke.

CULMINATION, in astronomy, the passage of any heavenly body over the meridian, or its greatest altitude for that day. See GLOBES, *use of*.

CULPRIT, is not (as is vulgarly imagined) an opprobrious name given to the prisoner before he is found guilty, but it is the reply of the clerk of arraigns to the prisoner, after he had pleaded Not Guilty; which plea was anciently entered upon the minutes in an abbreviated form, *non cul'*; upon which the clerk of the arraigns, on behalf of the crown, replies that the prisoner is guilty, and that he is ready to prove him so; which is done by a like kind of abbreviation, cul'prit, signifying that the king is ready to prove him guilty (from cul. that is, culpabilis, guilty; and prit, præsto sum, I am ready to verify it). 4 Black. 339.

CULM, or CULMUS. See BOTANY.

CULTURE *of lands*. See HUSBANDRY.

CULVERIN, a long slender piece of ordnance or artillery, serving to carry a ball to a great distance. Manege derives the word from the Latin colubrina; others from coluber, "snake;" either on account of the length and slenderness of the piece, or of the ravages it makes. There are three kinds of culverins, viz. the extraordinary, the ordinary, and the least-sized. 1. The culverin extraordinary has $5\frac{1}{2}$ inches bore; its length 32 calibers, or 18 feet; weighs 4800 pounds; its load above 12 pounds; carries a shot $5\frac{1}{4}$ inches diameter, of twenty pounds weight. 2. The ordinary culverin is 12 feet long; carries a ball of 17 pounds 5 ounces; caliber $5\frac{1}{2}$ inches; its weight 4500 pounds. 3. The culverin of the least size has its diameter 5 inches; is 12 feet long; weighs about 4000 pounds; carries a shot $3\frac{3}{4}$ inches diameter, weighing 14 pounds 9 ounces.

CULVERTAIL, among shipwrights, signifies the fastening or letting of one timber into another, so that they cannot slip out, as the corlings into the beams of a ship.

CUMINUM, *cummin*, a genius of the digynia order, in the pentandria class of plants, and in the natural method ranking under the 45th order, umbellatæ. The fruit is ovate and striated; there are four partial umbels, and the involucra are quadrifid. There is but one species, viz. the cyminum. It is an annual plant, perishing soon after the seed is ripe. It rises nine or ten inches high in the warm countries, where it is cultivated, but seldom rises above four in this country. It has sometimes flowered very well here, but never brings its seeds to perfection. The leaves are divided into long narrow segments, like those of fennel, but much smaller: they are of a deep green, and generally turned backward at their extremity. The flowers grow in small umbels at the top of the stalks: they are composed of five unequal petals, of a pale blueish colour, which are succeeded by long, channeled, aromatic seeds. The plant is propagated for sale in the island of Malta. The seeds have a bitterish warm taste, accompanied with an aromatic flavour, not of the most agreeable kind. They are retained in the revised Pharmacopœia of the college, particularly in the emplastrum cumini.

CUNICULUS, in mining, a term used by authors in distinction from puteus, to express the several sorts of passages and cuts in these subterranean works. The cuniculi are those direct passages in mines where they walk on horizontally; but the putei are the perpendicular cuts or descents. The miners in Germany call these by the name stollen and schachts; the first word expressing the horizontal, and the second the perpendicular cuts.

CUNILA, in botany, a genus of the monogynia order, in the monandria class of plants, and in the natural method ranking under the 42d order, verticillatæ. The corolla is ringent, with its upper lip erect and plain; there are two filaments, castrated, or wanting antheræ; the seeds are four. There are four species, none of which has any remarkable property.

CUNNINGHAMIA, a genus of the tetrandria monogynia class and order. The calyx is four-toothed; the corolla four-cleft, with a short tube; berry crowned with a two-seeded nut. There is one species.

CUNONIA, a genus of the digynia order, in the decandria class of plants, and in the natural method ranking with those of which the order is doubtful. The corolla is pentapetalous; the calyx pentaphyllous; the capsule bilocular, acuminated, polyspermous; the styles longer than the flower. There is one species, a native of the Cape.

CUOGOLO, in natural history, the name of a stone much used by the Venetians in glass-making, and found in the river Fesino. It is a small stone of an impure white, of a shattery texture, and is of the shape of a pebble.

CUP-*galls*, in natural history, a name given by authors to a very singular kind of galls, found on the leaves of the oak and some other trees. They are of the figure of a cup, or drinking-glass without its foot, being regular cones adhering by their point or apex to the leaf; and the top or broad part is hollowed a little way, so that it appears like a drinking-glass with a cover, which was made so small as not to close it at the mouth, but fall a little way into it. This cover is flat, and has in the centre a very small protuberance, resembling the nipple of a woman's breast. This is of a pale green, as is also the whole of the gall, excepting only its rim that runs round about the top: this latter is of a scarlet colour, and that very beautiful. See CYNIPS.

CUPANIA, a genus of the monadelphia order, in the monœcia class of plants, and in the natural method ranking under the 38th order, tricoccæ. The calyx of the male is triphyllous; the corolla pentapetalous; the stamina five. The calyx of the female is triphyllous; the corolla tripetalous; the style trifid; and a pair of seeds. There are three species, small trees of the West Indies, which possess no remarkable property.

CUPEL, in metallurgy, a small vessel which absorbs metallic bodies when changed by fire into a fluid scoria; but retains them as long as they continue in their metallic state. One of the most proper materials for making a vessel of this kind is the ashes of animal bones; there is scarcely any other substance which so strongly resists vehement fire, and which so readily imbibes metallic scoriæ. See CHEMISTRY.

CUPELLATION, the act of refining gold or silver by means of a cupel. For this purpose another vessel called a muffle is made use of, within which one or more cupels are placed. The muffle is placed upon a grate in a proper furnace, with its mouth facing the door, and as close to it as may be. The furnace being filled up with

fuel, some lighted charcoal is thrown on the top, and what fuel is afterwards necessary is supplied through a door above. The cupels are set in the muffle; and being gradually heated by the successive kindling of the fuel, they are kept red-hot for some time, that the moisture which they strongly retain may be completely dissipated; for if any vapours should issue from them after the metal is put in, they would occasion it to sputter, and a part of it to be thrown off in little drops. In the sides of the muffle are some perpendicular slits, with a knob over the top of each, to prevent any small pieces of coals or ashes from falling in. The door, or some apertures in it, being kept open, for the inspection of the cupels, fresh air enters into the muffle, and passes off through these slits; by laying some burning charcoal on an iron plate before the door, the air is heated before its admission; and by removing the charcoal, or supplying more, the heat in the cavity of the muffle may be somewhat diminished or increased more speedily than can be effected by suppressing or exciting the fire in the furnace on the outside of the muffle. The renewal of the air also is necessary for promoting the scorification of the lead. See CHEMISTRY.

The cupel being of a full red heat, the lead, cast into a smooth bullet that it may not scratch or injure the surface, is laid lightly in the cavity; it immediately melts, and then the gold or silver to be cupelled is cautiously introduced, either by means of a small iron ladle, or by wrapping them in paper, and dropping them on the lead with a pair of tongs. The quantity of lead should be at least three or four times that of the fine metal; but when gold is very impure, it requires 10 or 12 times its quantity of lead for cupellation. It is reckoned that copper requires for its scorification about 10 times its weight of lead; that when copper and gold are mixed in equal quantities, the copper is so much defended by the gold, as not to be separable with less than 20 times its weight of lead; and that when copper is in very small proportion, as a 20th or 30th part of the gold or silver, upwards of 60 parts of lead are necessary for one of the copper. The cupel must always weigh at least half as much as the lead and copper, for otherwise it will not be sufficient for receiving half the scoria; there is little danger, however, of cupels being made too small for the quantity of a gold assay.

The mixture being brought into thin fusion, the heat is to be regulated according to the appearances, and in this consists the principal nicety of the operation. If a various-coloured skin rises at the top, which liquefying, runs off to the sides, and is there absorbed by the cupel, visibly staining the parts it enters; if a fresh scoria continually succeeds, and is absorbed nearly as fast as it is formed, only a fine circle of it remaining round the edge of the metal; if the lead appears in gentle motion, and throws up a fume a little way from the surface; then the fire is of the proper degree, and the process goes on successfully.

Such a fiery brightness of the cupel as prevents its colour from being distinguished, and the fumes of the lead rising up almost to the arch of the muffle, are marks of too strong a heat: though it must be observed, that the elevation of the fumes is not always in proportion to the degree of heat; for if the heat greatly exceeds the due limits, both the fumes and ebullition will entirely cease. In these circumstances the fire must necessarily be diminished; for while the lead boils and smokes vehemently, its fumes are apt to carry off some part of the gold; the cupel is liable to crack, from the hasty absorption of the scoria; and part of the gold and silver is divided into globules, which lying discontinued on the cupel after the process is finished, cannot easily be collected; if there is no ebullition or fumes, the scorification does not appear to go on. Too weak a heat is known by the dull redness of the cupel, by the fume not rising from the surface of the lead, and the scoria appearing like bright drops in languid motion, or accumulated, or growing consistent all over the metal. The form of the surface affords also an useful mark of the degree of heat; the stronger the fire the more convex is the surface, and the weaker the more flat; in this point, however, regard must be had to the quantity of metal; a large quantity being always flatter than a small one in an equal fire.

Towards the end of the process, the fire must be increased; for the greatest part of the fusible metal lead being now worked off, the gold and silver will not continue melted in the heat that was sufficient before. As the last remains of the lead are separating, the rainbow colours on the surface become more vivid, and variously intersect one another with quick motions. Soon after, disappearing all at once, a sudden luminous brightness of the button of gold and silver shows the process to be finished. The cupel is then drawn forwards towards the mouth of the muffle; and the button, as soon as grown fully solid, taken out.

CUPHEA, in botany, a genus of the monogynia order, in the dodecandria class of plants. The calyx is six toothed; the corolla six petalled, purple colour; annual. There is but one species known, a native of Pensylvania; flowers in September. (*c*)

CUPOLA, in architecture, a spherical vault; or the round top of the dome of a church, in form of a cup inverted.

CUPPING, in surgery, the operation of applying cupping-glasses for the discharge of blood, and other humours, by the skin. See SURGERY.

CUPRESSUS, the cypress-tree, a genus of the monadelphia order, in the monœcia class of plants, and in the natural method ranking under the 51st order, coniferæ. The male calyx is a scale of the catkin; there is no corolla; the antheræ are four, sessile, and without filaments. The calyx of the female is a scale of the strobilus, and unifloroius; instead of the stylus there are hollow dots; the fruit is an angulated nut. There are seven species; the most remarkable are the following: 1. The sempervirens, or evergreen, with an upright straight stem, closely branching all round, almost from the bottom upwards, into numerous quadrangular branches, rising in the different varieties from 15 to 40 or 50 feet in height, with small, narrow, erect evergreen leaves, placed imbricatim, and flowers and fruit from the sides of the branches. 2. The thyoides, or evergreen American cypress, commonly called white cedar, has an upright stem branching out into numerous two-edged branches, rising 20 or 30 feet high, ornamented with the flat evergreen leaves, imbri-

cated like the arbor vitæ, and small blue cones, the size of juniper-berries. 3. The disticha, or deciduous American cypress, has an erect trunk, retaining a large bulk, branching wide and regular; grows 50 or 60 feet high, with small spreading deciduous leaves, arranged distichous, or along two sides of the branches. All these species are raised from seeds, and will sometimes also grow from cuttings; but those raised from seeds prove the handsomest plants. The seeds are procured in their cones from the seedsmen, and by exposing them to a moderate heat, they readily open, and discharge their seeds freely. The season for sowing them is any time in March; and they grow freely on a bed of common light earth, especially the first and third species.

The wood of the first species is said to resist worms, moths, and putrefaction, and to last many centuries. The coffins in which the Athenians were used to bury their heroes, were made, says Thucydides, of this wood; as were likewise the chests containing the Egyptian mummies. The doors of St. Peter's church at Rome were originally of the same materials. These, after lasting upwards of 600 years, at the end of which they did not discover the smallest tendency to decay, were removed by order of pope Eugenius IV. and gates of brass substituted in their place. The same tree has been extolled as a remedy in pulmonic diseases, from its supposed property of meliorating the air by its balsamic exhalations; upon which account many ancient physicians of the eastern countries used to send their patients to the island of Candia, where these trees grew in great abundance. In that island, says Miller, the cypress-trees were so lucrative a commodity, that the plantations were called dos filæ; the felling of one of them being reckoned a daughter's portion. Cypress, says Mr. Pococke, is the only tree that grows towards the top of mount Lebanon, and being nipped by the cold, grows like a small oak. Noah's ark is commonly supposed to have been made of this kind of wood.

CURATE, is he who represents the incumbent of a church, parson, or vicar, and performs divine service in his stead; and in case of pluralities of livings, or where a clergyman is old and infirm, it is requisite there should be a curate to perform the cure of the church. He is to be licensed and admitted by the bishop of the diocese, or by an ordinary having episcopal jurisdiction: and when a curate has the approbation of the bishop, he usually appoints the salary too; and in such case, if he is not paid, the curate has a proper remedy in the ecclesiastical court, by a sequestration of the profits of the benefice; but if he has no licence from the bishop, he is put to his remedy at common law, where he must prove the agreement.

CURATELLA, a genus of the digynia order, belonging to the polyandria class of plants, and in the natural method ranking with those of which the order is doubtful. The calyx is pentaphyllous; the petals four; the styles two; the capsules bipartite, with the cells dispermous.

CURATOR, among civilians, a person regularly appointed to manage the affairs of minors, or persons mad, deaf, dumb, &c. In countries where the civil law prevails, minors have tutors assigned them till they are of the age of 14, between which and 25 they have curators appointed them. There are also curators for the estate of debtors, and of persons dying without heirs.

CURCULIO, in zoology, a genus of insects belonging to the order of coleoptera. The feelers are subclavated, and rest upon the snout, which is prominent and horny. These insects are divided into the following families: 1. Those which have the rostrum longer than the thorax, and whose thighs are simple. 2. Those which have the rostrum longer than the thorax, and the thighs thicker and made for leaping. 3. Those which have the rostrum longer than the thorax, and the thighs dentated. 4. Those which have dentated thighs, and a rostrum shorter than the thorax. 5. Those whose thighs are without teeth or spines, and the rostrum shorter than the thorax. There are no less than 95 species, principally distinguished by their colour.

The larvæ of the curculiones do not differ from those of most coleopterous insects. They bear a resemblance to oblong soft worms. They are provided anteriorly with six scaly legs, and the head likewise is scaly. But the places where those larvæ dwell, and their transformations, afford some singularities. Some species of them, that are dreaded for the mischief they do in granaries, find means to introduce themselves, while yet small, into grains of corn, and there make their abode. It is very difficult to discover them, as they lie concealed within the grain. There they grow at leisure, enlarging their dwelling-places as they grow, at the expense of the interior meal of the grain on which they feed. Corn-lofts are often laid waste by these insects, whose numbers are sometimes so great as to devour and destroy all the grain. When the insect, after having eaten up the meal, is come to its full size, it remains within the grain, hidden under the empty husk, which subsists alone; and there transformed, it becomes a chrysalis, nor does it leave it till a perfect insect, making its way through the husk of the grain. It is no easy matter to discover by the eye the grains of corn thus attacked and hallowed out by those insects, as they outwardly appear large and full: but the condition the curculio has reduced them to, renders them much lighter; and if you throw corn infested by these insects into the water, all the spoiled grains will swim, and the rest sink to the bottom. Other larvæ of curculiones are not so fond of corn, but fix in the same manner on several other seeds. Beans, peas, and lentils, that are preserved dry, are liable to be eaten by these little animals; which prey upon the inward part of the grain, where they have taken up their habitation, and do not come forth till they have completed their transformation, by breaking through the outward husk of the grain: this is discoverable by casting those grains into water: those that swim are generally perforated by the curculiones. Other species are lodged in the inside of plants. The heads of artichokes and thistles are often bored through and eaten away by the larvæ of large curculiones. Another species smaller, but singular, pierces and inwardly consumes the leaves of elms. It frequently happens that almost all the leaves of an elm appear yellow, and, as it were, dead towards one of their edges, while the whole remainder of the leaf is green. Upon inspecting these leaves, the dead part appears to form a kind of bag or small bladder. The two laminæ or outward pellicles of the leaf, as well above as below, are entire, but distant and separated from each other; whilst the parenchyma that lies between them has been consumed by se-

veral small larvæ of the curculio, which have made themselves that dwelling, in which they may be met with. After their transformation they come forth, by piercing a kind of bladder, and give being to a curculio that is brown, small, and hard to catch, from the nimbleness with which it leaps. The property of leaping, allotted to this single species, depends on the shape and length of its hinder legs.

CURCUMA, *turmeric*, a genus of the monogynia order, in the monandria class of plants, and in the natural method ranking under the eighth order, scitamineæ. It has four barren stamina, with a fifth fertile. There are three species: 1. The rotunda, with a round root, having a fleshy-jointed root like that of ginger, but round; which sends up several spear-shaped oval leaves, that rise upwards of a foot high, and are of a sea-green colour. From between these arise the flower-stalks, supporting a loose spike of flowers of a pale yellowish colour, inclosed in several different spathæ, or sheaths, which drop off. The flowers are never succeeded by seeds in England. 2. The longa has long fleshy roots of a deep-yellow colour, which spread under the surface of the ground like those of ginger; they are about the thickness of a man's finger, having many round knotty circles, from which arise four or five large spear-shaped leaves, standing upon long foot-stalks. The flowers grow in loose scaly spikes on the top of the footstalks, which rise from the larger knobs of the roots, and grow about a foot high; they are of a yellowish-red colour, and shaped somewhat like those of the Indian reed. 3. The pallida, which differs from the others in being an annual plant. These plants grow naturally in India, whence the roots are brought to Europe for use. They are very tender, so will not live in this country unless kept constantly in a stove. They are propagated by parting the roots. The root communicates a beautiful but perishable yellow dye, with alum, to woollen, cotton, or linen. In medicine it is esteemed an aperient and emmenagogue, and of singular efficacy in the jaundice.

CURIA, in Roman antiquity, a certain division, or portion of a tribe. Romulus divided the people into 30 curiæ, or wards, whereof there were 10 in every tribe, that each might keep the ceremonies of their feasts and sacrifices in the temple, or holy place, appointed for every curia. The priest of the curia was called curio.

CURIA, in the English law, generally signifies a court; and has been taken for the customary tenants, who do their suit and service at the court of the lord.

CURIA *advisare vult*, a deliberation which a court of justice takes upon some point of difficulty that arises in a cause, before they give judgment.

CURIA *aquæ cursus*, a court held by the lord of the manor of Gravesend, for the better management of barges and boats that use the passage on the Thames between that place and London, &c.

CURIA *claudenda*, a writ that lies to compel a man to make a fence, or wall, between his lands and that of the plaintiff.

CURIOSUS, an officer of the Roman empire, during the middle age; when one or two were despatched annually into each province to take care that no frauds or abuses were committed with regard to the posts and roads, and to bring intelligence to court of what passed in the provinces. They answer nearly to what are called comptrollers.

CURRANS, or CURRANTS. See RIBES.

CURRANTS also signify a smaller kind of grapes brought principally from Zante and Cephalonia. They are gathered off the bunches, and laid to dry in the sun, and so put up in large butts. They are opening and pectoral, but are more used in the kitchen than in medicine.

CURRENT, in hydrography, a stream or flux of water in any direction. In the sea currents are either natural, occasioned by the diurnal motion of the earth round its axis, or accidental, caused by the waters being driven against promontories, or into gulphs and streights, where wanting room to spread, they are driven back, and thus disturb the ordinary flux of the sea. Dr. Halley makes it highly probable that in the Downs there are under-currents, by which as much water is carried out as is brought in by the upper currents.

CURRENTS, in navigation, are certain settings of the stream, by which ships are compelled to alter their course or velocity, or both, and submit to the motion impressed upon them by the current. The knowledge of them being so necessary an article in navigation, we shall show a more accurate way of discovering the way they set, together with their strength, than that of guessing by the ripplings of the water, and by the driving of the froth along shore. Take your ship's boat, with three or four men, a compass, a log-line with a large log to it, and a kettle or iron pot, with a coil or two of inch rope fastened to its bale. When at a proper distance from the ship, heave your kettle overboard, and let it sink 80 or 100 fathoms, which will ride the boat nearly as fast as if at anchor. Heave your log, and turn your half-minute glass, observing at the same time to set the drift of the log by the compass: then will the knots run out during the half-minute, give the current's strength, and the compass its setting. Now to know how to make proper allowances for currents, it is evident, if a current sets just with the course of the ship, then the motion of the ship is increased by as much as is the drift or velocity of the current; and if a current sets directly against the ship's course, then the motion is retarded in proportion to the velocity of the current. Hence it is plain. 1. If the velocity of the current be less than that of the ship, then the ship will get so much ahead, as is the difference of these velocities. 2. If the velocity of the current be greater than that of the ship, then the ship will fall so much astern as is the difference of these velocities. 3. If the velocity of the current be equal to that of the ship, then the ship will stand still, the one velocity destroying the other.

If the current thwarts the course of a ship, then it not only lessons or augments her velocity, but gives her a new direction; compounded of the course she steers, and the setting of the current. Suppose a ship sails by the compass directly south, 96 miles in 24 hours, in a current that sets east 45 miles in the same time: required the ship's true course and distance. It is evident that the ship will run upon the diagonal of a parallelogram, of which the sides are 96 and 45: the length of this diagonal is found to be 106 miles, equal to $\sqrt{96^2+45^2}$. See NAVIGATION.

CURRIERS. In England no currier shall use the trade of a butcher, tanner, &c. or shall curry skins insufficiently tanned, or gash any hide of leather, on pain of forfeiting for every hide or skin, 6*s*. 8*d*. If any currier do not curry leather sent to him, within 16 days between Michaelmas and Lady-day, and in eight days at other times, he shall on conviction thereof forfeit 5*l*. 12 Geo. II. c. 25. Every currier or dresser of hides in oil, shall annually take out a licence from the commissioners or officers of excise.

CURRYING, the method of preparing leather with oil, tallow, &c. The chief business is to soften and supple cows' and calves' skins, which make the upper-leathers and quarters of shoes, coverings of saddles, coaches, and other articles which must keep out water. 1. These skins, after coming from the tanner's yard, having many fleshy fibres on them, the currier soaks them some time in common water. 2. He takes them out, and stretches them on a very even wooden horse; then with a paring knife, he scrapes off the superfluous flesh, and puts them into soak again. 3. He puts them wet on a hurdle, and tramples them with his heels, till they begin to grow soft and pliant. 4. He soaks them in train oil, which, by its unctuous quality, is the best liquor for the purpose. 5. He spreads them on large tables, and fastens them at the ends. Then, with the help of an instrument called a pummel, which is a thick piece of wood, the under side of which is full of furrows crossing each other, he folds, squeezes, and moves them forwards and backwards several times, under the teeth of this instrument, which breaks their too great stiffness. This is what is properly called currying. The order and number of these operations are varied by different curriers, but the material part is always the same. 6. After the skins are curried, there may be occasion to colour them. The colours are black, white, red, yellow, and green: the other colours are given by the skinners, who differ from curriers in this, that they apply their colours on the flesh side, the curriers on the hair side. In order to whiten skins, they are rubbed with lumps of chalk, or white lead, and afterwards with pumice-stone. 7. When a skin is to be made black, after having oiled and dried it, he passes over it a puff dipt in water impregnated with iron; and after this first wetting, he gives it another in a water prepared with soot, vinegar, and gum arabic. These different dyes gradually turn the skin black, and the operations are repeated till it is of a shining black. The grain and wrinkles which contribute to the suppleness of calves' and cows' leather, are made by the reiterated folds given to the skin in every direction, and by the care taken to scrape off all hard parts on the coloured side.

CURSING *and swearing*, an offence against God and religion, and a vice of all others the most extravagant and unaccountable, as having no benefit or advantage attending it. [By the last act against this crime, if any person of the age of sixteen years or upwards, shall curse or swear by the name of God, Christ Jesus, or the Holy Ghost, every person so offending, being thereof convicted, shall forfeit and pay the sum of sixty-seven cents for every such profane curse or oath; and in case he or she shall refuse or neglect to pay the said forfeiture, or goods and chattels cannot be found, whereof to levy the same by distress, he or she shall be committed to the house of correction of the proper county, not exceeding twenty-four hours, for every such offence of which such person shall be convicted: and whosoever of the age of sixteen years or upwards, shall curse or swear by any other name or thing as aforesaid, and shall be convicted thereof, shall forfeit and pay the sum of forty cents for every such curse or oath; and in case such offender shall neglect or refuse to satisfy such forfeiture, or no goods or chattels can be found, whereof to levy the same by distress, he or she shall be committed to the house of correction of the proper county, not exceeding twelve hours for every such offence. (*b*)

CURSITOR, an officer or clerk belonging to the chancery, who make out original writs; of these there are 24 in number, and to each are allotted several counties.

CURSOR, in mathematical instruments, is any small piece that slides; as the piece in an equinoctial ring-dial that slides to the day of the month; the little label of brass divided like a line of sines, and sliding in a groove along the middle of another label, representing the horizon in the analemma; and likewise a brass point screwed on the beam-compasses, which may be moved along the beam for the striking of greater or less circles.

CURTATE *distance*, in astronomy, the distance of a planet from the sun to that point where a perpendicular let fall from the planet meets with the ecliptic.

CURTEYN, *curtana*, in the British customs, king Edward the Confessor's sword, borne before the prince at coronations. Its point is said to be broken off, as an emblem of mercy.

CURTIN, Curtain, or Courtin, in fortification, is that part of the rampart of a place which is betwixt the flank of two bastions bordered with a parapet five feet high, behind which the soldiers stand to fire upon the covered way into the moat. As it is the best defended of any part of the rampart, besiegers never carry on their attacks against the curtain, but against the faces of the bastions, because of their being defended only by one flank.

CURTISA, a genus of the tetrandria monogynia class and order. The calyx is four parted; petals four; drupe superior, roundish, succulent, with a four or five celled nut. There is one species, a tree of the Cape.

CURVATURE *of a line*, is the peculiar manner of its bending or flexure, by which it becomes a curve of such and such peculiar properties.

Any two arches of curve lines touch each other when the same right line is the tangent of both at the same point; but when they are applied upon each other in this manner, they never perfectly coincide, unless they are similar arches of equal and similar figures; and the curvature of lines admits of indefinite variety. Because the curvature is uniform in a given circle, and may be varied at pleasure in them by enlarging or diminishing their diameters, the curvature of circles serves for measuring that of other lines.

Of all the circles that touch a curve in any given point, that is said to have the same curvature with it, which touches it so closely, that no circle can be drawn

through the point of contact between them: and this circle is called the circle of curvature; its centre, the centre of curvature; and its semidiameter, the ray of curvature belonging to the point of contact. As in all figures, rectilinear ones excepted, the position of the tangent is continually varying, so the curvature is continually varying in all curvilinear figures, the circle only excepted. As the curve is separated from its tangent by its curvature, so it is separated from the circle of curvature in consequence of the increase or decrease of its curvature; and as its curvature is greater or less, according as it is more or less inflected from the tangent, so the variation of curvature is greater or less according as it is more or less separated from the circle of curvature.

When any two curve lines touch each other in such a manner that no circle can pass between them, they must have the same curvature; for the circle that touches the one so closely that no circle can pass between them, must touch the other in the same manner. And it can be made appear, that circles may touch curve lines in this manner; that there may be indefinite degrees of more or less intimate contact between the curve and the circle of curvature; and that a conic section may be described that shall have the same curvature with a given line at a given point, and the same variation of a curvature, or a contact of the same kind with the circle of curvature. The rays of curvature of similar arcs, in similar figures, are in the same ratio as any homologous lines of these figures, and the variation of curvature is the same.

CURVE, in geometry, a line which, running on continually in all directions, may be cut by one right line in more points than one.

In a curve, the line AD (See Pl. XXXIX. Miscel. fig. 28), which bisects all the parallel lines MN, is called a diameter, and the point A, where the diameter meets the curve, is called the vertex; if AD bisect all the parallels at right angles, it is called the axis. The parallel lines MN are called ordinates, or applicates, and their halves P M, or P N, semi-ordinates. The portion of the diameter A P, between the vertex, or any other fixed point, and an ordinate, is called the abscissa; also the concourse of all the diameters, if they meet all in one point, is the centre. This definition of the diameter, as bisecting the parallel ordinates, respects only the conic sections, or such curves as are cut only in two points by the ordinates; but in the lines of the 3d order, which may be cut in three points by the ordinates, then the diameter is that line which cuts the ordinates so, that the sum of the two parts that lie on the one side of it, shall be equal to the part on the other side; and so on for curves of higher orders; the sum of the parts of the ordinates on one side of the diameter, being always equal to the sum of the parts on the other side of it.

Curve lines are distinguished into algebraical or geometrical, and transcendental or mechanical.

Algebraical or geometrical curves are those in which the relation of the abscisses A P, to the ordinates P M, can be expressed by a common algebraic equation.

And transcendental or mechanical curves are such as cannot be so defined or expressed by an algebraical equation.

Thus suppose, for instance, the curve be the circle, (Pl. Mis. fig. 28) and that the radius A C $= r$, the abscissa A P $= x$, and the ordinate P M $= y$; then, because the nature of the circle is such, that the rectangle A P $\times$ P B is always $=$ P M^2, therefore the equation is $x \cdot \overline{2r - x} = y^2$, or $2rx - x^2 = y^2$, defining this curve, which is therefore an algebraical or geometrical line. Or suppose C P $= x$, then is C M^2 — C P^2 $=$ P M^2, that is, $r^2 - x^2 = y^2$; which is another form of the equation of the curve.

The doctrine of curve lines in general, as expressed by algebrical equations, was first introduced by Des Cartes, who called algebraical curves geometrical ones, as admitting none else into the construction of problems, nor consequently into geometry. But Newton, and after him Leibnitz and Wolfius, are of another opinion; and think, that in the construction of a problem, one curve is not to be preferred to another for its being defined by a more simple equation, but for its being more easily described.

Algebraical or geometrical lines are best distinguished into orders according to the number of dimensions of the equation expressing the relation between its ordinates and abscisses, or, which is the same thing, according to the number of points in which they may be cut by a right line. And curves of the same kind or order are those whose equations rise to the same dimension. Hence, of the first order, there is the right line only; of the second order of lines, or the first order of curves, are the circle and conic sections, being four species only, viz. $dx - x^2 = y^2$ the circle, $\frac{c^2}{d^2} \cdot \overline{dx - x^2} = y^2$ the ellipse, $\frac{c^2}{d^2} \cdot dx + x^2 = y^2$ the hyperbola, and $dx = y^2$ the parabola; the lines of the third order, or curves of the second order, are expressed by an equation of the third degree; having three roots; and so on. Of these lines of the third order, Newton wrote an express treatise, under the title of Enumeratio Linearum Tertii Ordinis, showing their distinctive characters and properties, to the number of 72 different species of curves; but Mr. Stirling afterwards added four more to that number, and Mr. Nic. Bernouilli and Mr. Stone added two more.

As to the curves of the second order, sir Isaac Newton observes, they have parts and properties similar to those of the first: thus, as the conic sections have diameters and axes, the lines cut by these are called ordinates, and the intersection of the curve and diameter, the vertex. So in curves of the second order, any two parallel lines being drawn so as to meet the curve in three points, a right line cutting these parallels, so as that the sum of the two parts between the secant and the curve on one side, is equal to the third part terminated by the curve on the other side, will cut in the same manner all other right lines parallel to these, and meet the curve in three parts, so as that the sum of the two parts on one side will be still equal to the third part on the other side.

These three parts, therefore, thus equal, may be called ordinates or applicates; the secant may be styled the diameter; the intersection of the diameter and the curve the vertex; and the point of concourse of any two diameters the centre. And if the diameter be normal to the ordinates, it may be called axis; and that point where all the diameters terminate, the general centre. Again, as an hyperbola of the first order has two asymptotes, that of the second three, that of the third four, &c. and

as the parts of any right line lying between the conic hyperbola and its true asymptotes are every where equal, so in the hyberbola of the second order, if any right line be drawn cutting both the curve and its three asymptotes in three points, the sum of the two parts of that right line being drawn the same way from any two asymptotes to two points of the curve, will be equal to a third part drawn a contrary way from the third asymptote to a third point of the curve. Again, as in conic sections not parabolical, the square of the ordinate, that is, the rectangle under the ordinates drawn to contrary sides of the diameter, is to the rectangle of the parts of the diameter which are terminated at the vertices of the ellipsis or hyperbola, as the latus rectum is to the latus transversum; so in nonparabolic curves of the second order, a parallelopiped under the three ordinates is to a parallelopiped under the parts of the diameter, terminated at the ordinates, and the three vertices of the figure, in a certain given ratio; in which ratio, if you take three right lines situated at the three parts of the diameter between the vertices of the figure, one answering to another, then these three right lines may be called the latera recta of the figure, and the parts of the diameter between the vertices, the latera transversa. And, as in the conic parabola, having to one and the same diameter but one only vertex, the rectangle under the ordinates is equal to that under the part of the diameter cut off between the ordinates and the vertex and the latus rectum; so in curves of the second order, which have but two vertices to the same diameter, the parallelopiped under three ordinates, is equal to the parallelopiped under the two parts of the diameter cut off between the ordinates and those two vertices and a given right line, which therefore may be called the latus rectum. Moreover, as in the conic sections, when two parallels terminated on each side of the curve, are cut by two other parallels terminated on each by the curve, the first by the third, and the second by the fourth; as here the rectangle under the parts of the first is to the rectangle under the parts of the third, as the rectangle under the parts of the second is to that under the parts of the fourth; so when four such right lines occur in a curve of the second kind, each in three points, then shall the parallelopiped under the parts of the first right line, be to that under the parts of the third, as the parallelopiped under the parts of the second line, to that under the parts of the fourth. Lastly, the legs of curves, both of the first, second, and higher kinds, are either of the parabolic or hyperbolic kind; an hyperbolic leg being that which approaches infinitely towards some asymptote; a parabolic, that which has no asymptote. These legs are best distinguished by their tangents: for if the point of contact go off to an infinite distance, the tangent of the hyperbolic leg will coincide with the asymptote; and that of the parabolic leg recede infinitely and vanish. The asymptote, therefore, of any leg is found by seeking the tangent of that leg to a point infinitely distant; and the bearing of an infinite leg is found by seeking the position of a right line parallel to the tangent, when the point of contact is infinitely remote: for this line tends the same way towards which the infinite leg is directed. For the other properties of curves of the second order, we refer the reader to Mr. Maclaurin's treatise De Linearum Geometricarum Proprietatibus generalibus.

Sir Isaac Newton reduces all curves of the second order to the four following particular equations, still expressing them all. In the first, the relation between the ordinate and the abscise, making the abscise x and the ordinate y, assumes this form, $xy^2+ey=ax^1+bx^2+cx+d$. In the second case, the equation takes this form, $xy=ax^3+bx^2+cx+d$. In the third case, the equation is $y^2=ax^3+bx^2+cx+d$. And in the fourth case, the equation is of this form, $y+ix^3+bx^2+cx+d$.

CURVES, *family of*, according to Wolfius, is a congeries of several curves of different kinds, all defined by the same equation of an indeterminate degree, but differently, according to the diversity of their kinds. For example: let the equation of an indeterminate degree be $a^{m-1}x=y^m$. If $m=2$, ax will be equal to y^2. If $m=3$, then will $a^2x=y^3$. If $m=4$, then will $a^3x=y^4$, &c. all which curves are said to be of the same family. The equations, however, by which the families of curves are defined, must not be confounded with transcendental ones; though with regard to the whole family they be of an indeterminate degree, yet with respect to each several curve of the family, they are determinate; whereas transcendental equations are of an indefinite degree with respect to the same curve. The genesis and properties of particular curves, as the conchoid, cycloid, &c. see under their proper heads CONCHOID. CYCLOID. &c.

CURULE *chair*, in Roman antiquity, a chair adorned with ivory, wherein the great magistrates of Rome had a right to sit, and be carried.

CUSCUTA, *dodder*, a genus of the digynia order, in the tetrandria class of plants, and in the natural method ranking under those of which the order is doubtful. The calyx is quadrifid; the corolla monopetalous; the capsule bilocular. There are four species, one of which is a native of Britain, viz. the Europæa, dodder, hell-weed, or devil's-guts. This is a very singular plant, almost destitute of leaves, parasitical, creeping, fixing itself to whatever is next to it. It decays at the root, and afterwards is nourished by the plant which supports it. Hops, flax, and nettles, are its common support, but principally the common nettle. Its blossoms are white. As soon as the shoots have twined about an adjacent plant, they send out from their inner surface a number of little vesicles or papillæ, which attach themselves to the bark or rind of the plant. By degrees the longitudinal vessels of the stalk, which appear to have accompanied the vesicles, shoot from their extremities, and make their way into the softer plant, by dividing the vessels, and insinuating themselves into the tenderest part of the stalk; and so intimately are they united with it, that it is easier to break than to disengage them from it. The whole plant is bitter. It affords a pale reddish colour. Cows, sheep, and swine, eat it; horses refuse it; goats eat it reluctantly.

CUSSONIA, a genus of the pentandria digynia class and order. The petals are three-cornered; margin of the receptacle divided into a five-toothed calyx. There are two species, natives of the Cape.

CUSTODE *admittendo*, and *custode amovendo*, are writs for the admitting or removing of guardians.

CUSTOM, is a law or right, not written, which being established by long use, and the consent of our ancestors, has been and is daily practised. If it is to be proved by record, the continuance of a hundred years will serve. Custom is either general or particular. General, when allowed through all the country. Particular is that which belongs to this or that county, as gavelkind to Kent. See GAVELKIND.

General customs which are used throughout England, and are the common law, are to be determined by the judges: but particular customs, such as are used in some certain towns, boroughs, cities. &c. shall be determined by a jury. 1 Inst. 110. But the judges of the courts of king's-bench and common-pleas, can overrule a custom, though it be one of the customs of London, if against natural reason. 1 Mod. 212.

CUSTOM of London. The ancient city of London, being the metropolis and chief town for trade and commerce within the kingdom, it was necessary, that it should have certain customs and privileges for its better government, which though derogatory from the general law of the realm, yet, being for the benefit of the citizens, and for the advantage of those who trade to and from the city, have not only been allowed good by the judgments in the superior courts, but have also been confirmed by several acts of parliament.

The customs of London differ from all others in point of trial, for if any of the customs are pleaded and denied, and issue is taken thereupon, the existence of such customs shall be tried by a writ directed to the mayor and aldermen, to certify whether there is such a custom or not, and they shall make their certificate by the mouth of the recorder.

These customs of London relate to divers particulars with regard to trade, apprentices, widows, orphans, and a variety of other matters; the custom relative to the distribution of a freeman's estate, extends only to cases of intestacy, or express agreements made in consideration of marriage. It is a custom of London, that where a person is educated in one trade, he may set up another; that where a woman uses a trade, without her husband, she is chargeable alone, as a feme sole merchant, and if condemned, shall be put in prison till she pays the debt; likewise the bail for her are liable, if she absent herself, and the husband, in these cases, shall not be charged. If a debtor be a fugitive, by the custom of London, he may be arrested before the day, in order to find better security, &c. These are customs of this city, different from those of other places.

CUSTOM of merchants. If a merchant gives a character of a stranger to one who sells him goods, he may be obliged to satisfy the debt of the stranger for the goods sold, by the custom of merchants. And when two persons are found in arrears, upon an account grounded on the custom of merchants, either of them may be charged to pay the whole sum due. See BILLS OF EXCHANGE, BANKRUPTS, INSURANCE, &c.

CUSTOMS, taxes levied upon goods when exported from or imported into a state. This mode of raising a public revenue is of great antiquity, as it may be traced back to the time of Solomon; but in modern times it has been extended by different states to almost every article of commerce. It is a mode of taxation generally less objected to than any other, as most persons pay their share of the duty in the price of the article from which it arise, without distinguishing the tax; if, however, these duties are high, they become a great impediment to foreign trade, and give rise to smuggling; of this truth the Dutch were well convinced, and long derived great commercial advantages from the very low duties they imposed on the importation and exportation of merchandize. Duties on goods imported into a country were originally laid upon the subjects of the realm under the pretence of defraying the charges of guarding the coasts from pirates; and upon foreign merchants for the liberty given them by the sovereign of trading in his dominions. The custom-house duties in Great Britain are principally levied either according to the supposed value of the different commodities conformably to particular rates, or in proportion to the weight or measurement of the articles, making some difference according to the country whence the goods are brought, and giving advantages to the ships belonging to and manned by British subjects over those of a different description.

The customs of England were formerly divided into three branches: viz. 1st, The duties upon wool and leather; 2. A duty upon wine, which being imposed at so much a ton was called a tonnage; and 3. A duty upon all other goods, which being imposed at so much in the pound of their supposed value, was called a poundage. In the 47th Edward III. a duty of six-pence in the pound was imposed on all goods exported or imported, except wool, wool-fells, leather, and wine, on which particular duties had been granted before. In 14th Rich. II. it was raised to one shilling in the pound, but three years afterwards was again reduced to six-pence. It was raised to eight-pence in 2d Hen. IV. and in the fourth year of the same prince to one shilling, from which time to the 9th of Wil. III. it continued at one shilling in the pound. The duties of tonnage and poundage were generally granted by the same act, and were called the subsidy of tonnage and poundage. The subsidy of poundage having continued so long at 1s. in the pound or at five per cent. a subsidy came in the language of finance to denote a general duty of this kind at five per cent. These duties on the estimated value of goods imported or exported being liable to great inaccuracy and irregularity, the value of the different articles of commerce was ascertained by a book of rates, and computed on the quantities: there was a mode also by which duties were imposed on goods not rated; this was by a proportion on the real value as sworn to by the merchant. These principles once adopted, were pursued in every new subsidy; till the various additional duties imposed on articles of foreign trade in almost every year of war since the Revolution, with the occasional repeal of some of the old duties, and the different bounties and drawbacks allowed on exportation, caused an accumulation of perplexity, which in time had rendered the custom-duties a complete mass of confusion, attended with infinite inconvenience and delay in business. To remedy this evil, in the beginning of 1787, all the old duties were abolished, and a single duty on each article substituted in their stead. This arrangement, which was at the same time extended to the excise and stamp duties, may perhaps be recorded as the most useful financial measure of Mr. Pitt's

administration; and it is much to be regretted that although the same principle has been since resorted to, the many new duties which the exigencies of the state have rendered necessary, have again destroyed in some degree the simplicity effected, which had been attended with great practical convenience.

The progress of this branch of revenue shows the vast importance of foreign trade, if considered merely as furnishing a convenient mode of taxation. In the reign of king John, the whole of the duties payable by merchants in England were farmed for 1000 marks. From some acts of Henry III. it appears that considerable frauds were committed in the revenue of customs; it began however to increase, and in the reign of Edward III. the customs of the port of London alone amounted to 12,000 marks per annum. In 1590, the produce of the customs was considerably improved; and in 1613 it amounted to 148,075*l.* 7*s.* 8*d.* of which 109,572*l.* 18*s.* 4*d.* was collected in the port of London, while only 38,502*l.* 9*s.* 4*d.* was received from all the other ports of England. Of the total, 16,794*l.* 16*s.* 2*d.* arose from duties outward, and 61,280*l.* 11*s.* 6*d.* from duties inward. By the act of union in 1706, the customs of Scotland are stated at 30,000*l.* per annum, and those of England at 1,341,559*l.* per annum; since which period, the great increase of foreign trade, and the many new duties which have been imposed, have swelled the revenue of the customs to a far more important magnitude.

The following account shows the total gross receipt of the customs of Great Britain, for the year ending 5th January 1805, with the various payments to which it was subject, and the nett amount paid into the exchequer.

Balance in the hands of the collector, and of the receiver-general of Scotland, on the 5th January 1804	*L* 65,166	8	5¼
Bills arising and remitted out of the revenue of 1803, but which were not brought to account till 1804	200,003	3	5½
Gross receipt within the year	10,949,087	11	5¾
Total	*L* 11,214,257	3	4½
Paid drawbacks on exportation	355,768	11	7¾
Repayments on over-entries and damaged goods	98,513	0	5½
Bounties on exportation	1,132,678	16	2¾
Bounties for promoting national objects	304,056	3	8
Money imprest in the hands of out-port collectors	1,465	6	5
Paid towards the expenses of the civil government of Scotland	54,476	1	6¼
Advanced for the purchase of legal quays	76,689	12	6
Charges of management	566,999	6	10
Payments into the exchequer	8,357,871	5	8½
Balances in the hands of the collectors, and the receiver-general of Scotland, on the 5th January 1805	98,059	10	6½
Bills arising and remitted out of the revenue of 1804, but which were not brought to account till 1805	167,678	12	10¼
Total	*L* 11,214,257	3	4½

Deducting from the gross receipt of 10,949,078*l.* 11*s.* 5¾*d.* the sums paid for drawbacks on exportation, and as bounties for promoting national objects, together 659,824*l.* 15*s.* 3¾*d.*, the total nett produce of the year will be 10,289,262*l.* 16*s.* 2*d.* arising as follows:

From duties inwards	*L* 8,640,425	10	1¼
Duties outwards	658,968	14	5¾
Duties coastways	934,464	0	1
Quarantine tonnage duty	13,295	0	4
Remittances from the plantations	23,634	7	8
Condemned tobacco, wine, &c.	18,475	3	6
	L 10,289,262	16	2

The total produce of the customs of Ireland for the year ending 5th January 1805, may be stated thus:

From duties inwards	*L* 1,850,776	16	2¾
Duties outwards	22,237	15	3
Storage	1,794	13	4¼
Prizage	799	6	3
Light-money	5,944	16	0½
Fines and seizures, &c.	17,096	4	6¼
	L 1,898,649	11	7¾
Deduct appropriated duties	14,927	8	9
	L 1,883,722	2	10¾

The total produce of the customs of the united kingdom will therefore be as follows:

England	*L* 9,606,584	9	7¼
Scotland	682,678	6	6¾
Ireland	1,883,722	2	10¾
	L 12,172,984	19	0¾

The expense of collecting the customs of Great Britain is at the rate of 5*l.* 1*s.* 1*d.* per cent. on the gross revenue, or 6*l.* 5*s.* 2*d.* per cent. on the nett produce.

CUSTOM-HOUSE, an office established by the king's authority in maritime cities, or port-towns, for the receipt and management of the customs and duties of importation and exportation, imposed on merchandises, and regulated by books of rates. There are several custom-houses in the several parts of England, but the most considerable is that of London. It is under the direction of commissioners, appointed by patent, who have the charge and management of all the customs in all the ports of England. Other officers are a secretary, solicitor, receiver-general, comptroller-general, surveyor-general, &c. all holding their places by patents; with other inferior officers, appointed by warrant from the board of the treasury.

CUSTOM-OFFICERS shall not have any ships of their own, nor may they use merchandise, factorage, nor keep a tavern, &c. They are prohibited to trade in brandy, coffee, &c. or any excisable liquor, on pain of 50*l.* For taking a bribe they shall forfeit 100*l.*, and 500*l.* for mak-

ing collusive seizures, &c. Every merchant, making an entry of goods, either inwards or outwards, shall be despatched in such order as he comes in; and if any officer or his clerk shall for favour or reward, put any merchant or his servant, duly attending to make entries, by his turn, to draw any reward or gratuity from him, besides what is limited in the act of tonnage and poundage, &c. he shall be strictly admonished to his duty: or, if found faulty, he shall be discharged, and not permitted to sit any more in the custom-house. The officers who sit above in the custom-house of London, shall attend their several places, from nine to twelve in the forenoon; and one officer, or clerk, shall attend with the book, in the afternoon, during such time as the officers are appointed to wait at the water-side.

CUSTOS BREVIUM, the principal clerk belonging to the court of common pleas, whose business it is to receive and keep all the writs made returnable in that court, filing every return by itself; and, at the end of each term, to receive of the prothonotaries all the records of the nisi prius, called the posteas. The posteas are first brought in by the clerks of assize of every circuit to that prothonotary who entered the issue in the causes, in order to enter judgment; and after the prothonotary has entered the verdict and judgment thereupon into the rolls of the court, he delivers them over to the custos brevium, who binds them into a bundle. The custos brevium makes likewise entries of writs of covenant, and the concord upon every fine: by him also are made out exemplifications and copies of all writs and records in his office, and of all fines levied, which being engrossed, are divided between him and the chirographer, which last keeps the writ of covenant and the note, and the former the concord and foot of the fine. The custos brevium is made by the king's letters patent.

CUSTOS ROTULORUM, an officer who has the custody of the rolls and records of the sessions of peace, and also of the commission of the peace itself. He usually is some person of quality, and always a justice of the peace, of the quorum, in the county where he is appointed. This officer is made by writing under the king's sign manual, being the lord chancellor's warrant to put him in commission. He may execute his office by a deputy, and is empowered to appoint the clerk of the peace, but he may not sell the place under divers penalties.

CUT-WATER, or knee of the head, the sharpness of the head of the ship, below the beak; so called because it cuts or divides the water before it comes to the bow.

CUTICLE, *cuticula*, in anatomy, a thin membrane closely lying upon the skin, or cutis, of which it seems a part, and to which it adheres very firmly, being assisted by the intervention of the corpus reticulare.

CUTIS, the skin, in anatomy, is that strong thick covering which envelopes the whole external surface of animals. It is composed chiefly of two parts: a thin white elastic layer on the outside, which is called the epidermis, or cuticle; and a much thicker layer, composed of a great many fibres, closely interwoven, and disposed in different directions; this is called the cutis, or true skin. The epidermis is that part of the skin which is raised in blisters.

1. The epidermis is easily separated from the cutis by maceration in hot water. It possesses a very great degree of elasticity. It is totally insoluble in water and in alcohol. Pure fixed alkalies dissolve it completely; as does lime likewise, though slowly. Sulphuric and muriatic acids do not dissolve it, at least they have no sensible action on it for a considerable time; but nitric acid soon deprives it of its elasticity, and causes it to fall to pieces. It is well known that the living epidermis is tinged yellow almost instantaneously by nitric acid; but this effect does not take place, at least so speedily, when the dead cuticle is plunged in nitric acid altogether. If the cuticle is tinged with nitric acid, the application of ammonia to it is well known to give it instantaneously a deep orange-colour. Now as Mr. Hatchett has shown that this change is also produced upon coagulated albumen in the same circumstances, and as the epidermis resembles that substance in all the properties above detailed, it can scarcely be doubted that it is nothing else than a peculiar modification of coagulated albumen.

2. The cutis is a thick dense membrane, composed of fibres interwoven like the texture of a hat. When it is macerated for some hours in water, and agitation and pressure are employed to accelerate the effect, the blood, and all the extraneous matter with which it was loaded, are separated from it, but its texture remains unaltered. On evaporating the water employed, a small quantity of gelatine may be obtained. No subsequent maceration in cold water has any farther effect. When distilled it yields the same products as fabrina. The concentrated alkalies dissolve it, converting it into oil and ammonia. Weak acids soften it, render it transparent, and at last dissolve it. Nitric acid converts it into oxalic and fat, while, at the same time, azotic gas and prussic acid are omitted. When heated it contracts, and then swells, exhales a fetid odour, and leaves a dense charcoal, difficult to incinerate. By spontaneous decomposition in water or moist earth, it is converted into a fatty matter, and into ammonia, which compose a kind of soap. When allowed to remain long in water, it softens and putrefies, being converted into a kind of jelly. When long boiled in water it becomes gelatinous, and dissolves completely, constituting a viscid liquor, which, by proper evaporation is converted into glue. Hence the cutis of animals is commonly employed in the manufacture of glue.

From these facts the cutis appears to be a peculiar modification of gelatine enabled to resist the action of water, partly by the compactness of its texture, and partly by the viscidity of the gelatine of which it is formed; for those skins which dissolve most readily in boiling water afford the worst glue. Mr. Hatchett has observed, that the viscidity of the gelatine obtained from skins is nearly in versely as their flexibility, the suppliest hides always yielding the weakest glue; but this glue is very soon obtained from them by hot water. The skin of the eel is very flexible, and affords very readily a great proportion of gelatine. The skin of the shark also readily yields abundance of gelatine; and the same remark applies to the skins of the hare, rabbit, calf, and ox; the difficulty of obtaining the glue and its goodness always increasing with the toughness of the hide. The hide of the rhinoceros, which is exceedingly strong and tough, far surpasses the rest in the difficulty of solution and in the goodness of its glue. When skins are boiled they

gradually swell and assume the appearance of horn, then they dissolve slowly.

It is from the skin or cutis of animals that leather is formed; and the goodness of the leather, or at least its strength, depends in some measure on the toughness of the hides. Those easily soluble, as seal-skins, afford a weaker leather than those which are more difficultly soluble in water. The process by which the skins of animals are converted into leather is called tanning. It seems to have been known and practised in the earliest ages; but its nature was totally unknown till after the discovery of the tanning principle by Seguin. That chemist ascertained that leather is a compound of tan and skin; that it is to the tan that leather owes its insolubility and its power of resisting putrefaction. The subject has lately engaged the attention of Mr. Davy, who has examined it with his usual ingenuity, and added several important facts to our former knowledge.

When skins are to be tanned, the first step of the process is to deprive them of their hair and cuticle. This is either done by steeping them in water till they begin to putrefy, or by steeping them in lime and water. The lime seems to combine with the cuticle, and to render it brittle and easily detachable from the hide. It produces the same effect upon the hair and the matter at its root. When the hides have been steeped for a sufficient time, they are taken out, the hair, cuticle, &c. scraped off, and then they are washed in water.

After this preliminary process, the skins are subjected to different treatment according to the kind of leather which is to be made.

The large and thick hides are introduced for a short time into a strong infusion of bark. They are then said to be coloured. After this they are put into water slightly impregnated with sulphuric acid, or with the acid evolved during the fermentation of barley and rye. This renders them harder and denser than they were before, and fits them for forming sole-leather. Mr. Davy thinks, that by this process a triple compound is formed of the skin, tan, and the acid. The light skins of cows, those of calves, and all small skins, are steeped for some days in a lixivium made by the infusion of pigeon's dung in water. This lixivium is called the grainer. By this process they are rendered thinner, and softer and more proper for making flexible leather. Mr. Davy considers the effect of this lixivium to depend upon the fermentation which it undergoes; for dung that has undergone fermentation does not answer the purpose. After these preliminary processes, the skins are exposed to the action of the infusion of bark till they are converted into leather. The infusion of oak-bark contains two ingredients, namely tan and an extractive. The first is more soluble than the second. Hence in saturated infusions there is a much smaller proportion of tan than of extractive; whereas in weak infusions, the extractive bears a greater proportion to the tan. Mr. Davy considers it as doubtful whether the infusion of oak-bark contains any gallic acid. This chemist has ascertained, that the hides extract both the tan and extractive from the infusion, and leave nothing behind but pure water, provided they are employed in sufficient quantity. Hence it is obvious, that both the tan and extractive must enter into the composition of leather. The extractive gives the hide a brown colour, but does not render it insoluble in boiling water; the tan renders it insoluble, but its colour continues whitish. Hence it is likely that the lightest kinds of leather contain little else than tan, while the brown kinds contain both tan and extractive. While the hides are allowed to remain in the infusion of bark, they combine of course with tan and extractive, and the new compound is leather. Hence the reason of the increase of its weight.

Calf-skins, and those hides which are prepared by the grainer, are first steeped in weak infusions of oak-bark, and gradually removed to stronger and stronger, till they are completely impregnated, which takes up from two to four months. As the weak infusions contain a greater proportion of extractive, the consequence of this process is, that the skin combines in the first place with a portion of it, and afterwards with the tan. When saturated solutions of tan are employed, the leather is formed in a much shorter time. This was the process recommended by Seguin; but it has been observed, that leather tanned in this way is more rigid and more liable to crack than leather tanned in the usual way. Hence it is likely, as Mr. Davy has observed, that the union of the extractive is requisite to form pliable and tough leather. Leather rapidly tanned must be less equable in its texture than leather slowly tanned, as the surface must be saturated with tan before the liquid has time to penetrate deep. Mr. Davy has ascertained that skins, while tanning, seldom absorb more than one-third of their weight of vegetable matter.

Skins intended for sole leather are generally kept from the first in an infusion preserved nearly saturated by means of the strata of bark, with which they alternate. The full impregnation requires from ten to eighteen months. It is likely from this process that sole leather contains a greater proportion of tan than soft leather. While drying, it is smoothed with a rolling-pin, and beaten with a mallet, which must add considerably to its density.

3. As to the rete mucosum, or the mucous substance situated between the cutis vera and epidermis, its composition cannot be determined with precision, because its quantity is too small to admit of examination. It is known that the black colour of negroes depends upon a black pigment, situated in this substance. Oxymuriatic acid deprives it of its black colour, and renders it yellow. A negro, by keeping his foot for some time in water impregnated with that acid, deprived it of its colour, and rendered it nearly white; but in a few days the black colour returned again with its former intensity. This experiment was first made by Dr. Beddoes on the fingers of a negro. See ANATOMY, PHYSIOLOGY, and TANNING.

CUTTER of the tallies, an officer of the exchequer, whose business is to provide wood for the tallies, to cut or notch the sum paid upon them: and then to cast them into court to be written upon.

CUTTING, in heraldry, is used for the dividing a shield into two equal parts, from right to left, parallel to the horizon, or in the fesse-way.

CUTTING *in wood*, a particular kind of sculpture, or engraving, denominated from the matter on which it is employed. That sort of engraving which is called cutting in wood, was the first invented. It is used for initial

letters, head and tail pieces of books, and even for schemes and other figures, to save the expense of engraving on copper: and for prints and stamps for paper, calicoes, linen, &c. The art of cutting in wood was certainly carried to very great perfection about one hundred and fifty years ago, and has since been revived with very great success by Mr. Bewick, whose engravings of animals, &c. on wood may vie in beauty and excellence with the choicest copper-plates. The cutter in wood needs no other instruments than little sharp knives, chisels, and gravers of different sizes. The first thing he does, is to take a plank or block of pear-tree, or box, which he prepares of the size and thickness intended, and makes it very even and smooth on the side to be cut; on this block he draws the design with a pen or pencil just as it ought to be printed. Those who cannot draw their own designs, make use of those done by another, which they fasten on the block with paste, the strokes or lines being turned towards the wood: when the paper is dry, they wash it gently over with a spung dipped in water; which done, they take off the paper by degrees, still rubbing it a little with the tip of the finger, till there is nothing left on the block but the strokes of ink that form the design, which mark out so much of the block as is to be spared, or left standing; the rest they cut off and take away as curiously as they can, with the point of their sharp instruments.

CYANELLA, a genus of the hexandria monogynia class and order. The cor. is six-petalled; stamens lower, declined larger than the rest. There are three species; natives of Africa.

CYANILE, a stone commonly found in granite rocks. The primitive form of its crystals is a four-sided oblique prism, the sides of which are inclined at an angle of 130°. The base forms with one side of the prism an angle of 103°, with another an angle of 77°. It is sometimes crystallized in six-sided prisms. Its texture is foliated; fracture radiated; rays curved and interlaced; fragments long and splintery. It causes single refraction, and its specific gravity is from 3.5 to 3.6: feels somewhat greasy. Its colour is white, with shades of sky or Prussian blue.

CYATHUS, in Roman antiquity, a liquid measure, containing four ligulas, or half a pint English wine-measure, being 469⅔ solid inches.

CYCAS, in botany, a genus of plants belonging to the first natural order, palmæ. The fruit is a dry plum with a bivalved kernel. There are two species: 1. The circinalis, or sago-tree, grows spontaneously in the East Indies, and particularly on the coast of Malabar. It runs up with a straight trunk to 40 feet or more, having many circles the whole length, occasioned by the old leaves falling off; for, standing in a circular order round the stem, and embracing it with their base, whenever they drop, they leave the marks of their adhesion behind. The leaves are pinnated, and grow to the length of seven or eight feet. The pinnæ or lobes are long, narrow, entire, of a shining green, all the way of a breadth, lance-shaped at the point, are closely crowded together, and stand at right angles on each side the midrib, like the teeth of a comb. The flowers are produced in long bunches at the foot-stalks of the leaves, and are succeeded by oval fruit, about the size of large plums, of a red colour when ripe, and a sweet flavour. Each contains a hard brown nut, inclosing a white meat, which tastes like a chesnut.

This is a valuable tree to the inhabitants of India, as it not only furnishes a considerable part of their constant bread, but also supplies them with a great article of trade. The trunk contains a farinaceous substance, which they extract from it and make into bread in this manner: They saw the body into small pieces, and after beating them in a mortar, pour water upon the mass; this is left for some hours to settle. When fit, it is strained through a cloth; and the finer particles of the mealy substance running through with the water, the gross ones are left behind and thrown away. After the farinaceous part has sufficiently subsided, the water is poured off, and the meal being properly dried, is occasionally made into cakes and baked. These cakes are said to eat nearly as well as wheaten bread, and are the support of the inhabitants for three or four months in the year.

The same meal more finely pulverized, and reduced into granules, is what is called sago, which is sent into all parts of Europe, and sold in the shops as a great strengthener and restorative. There is a sort of sago made in the West Indies, and sent to Europe, in the same manner as that from the East; but the West India sago is far inferior in quality to the other. It is supposed to be made from the pith of the areca oleracea. See ARECA.

2. The cycas revoluta, or brood boom (or bread-tree) of the Hottentots, a plant discovered by professor Thunberg. The pith, or medulla, which abounds in the trunk of this little palm, Mr. Sparman informs us, is collected and tied up in dressed calf or sheep-skins, and then buried in the earth for the space of several weeks, till it becomes sufficiently mellow and tender to be kneaded up with water into a paste, of which they afterwards make small loaves or cakes, and bake them under the ashes. Other Hottentots not quite so nice, nor endued with patience enough to wait this tedious method of preparing it, are said to dry and roast the pith or marrow, and afterwards make a kind of frumenty of it. See Pl. XXXIX. N. H. fig. 154.

CYCLAMEN, SOWBREAD, a genus of the monogynia order, in the pentandria class of plants; and in the natural method ranking under the 21st order, preciæ. The corolla is verticillated, with the tube very short, and the throat prominent; the berry is covered with the capsule. There are five species, which produce many beautiful varieties. They are low, herbaceous, flowery perennials, of the tuberous-rooted kind, with numerous angular, heart-shaped, spotted, marbled leaves; with many fleshy footstalks six inches high, carrying monopetalous, five-parted, reflexed flowers, of various colours. All the varieties are extremely ornamented, and some of the flowers very fragrant. They may be planted in any of the common borders, but require to be sheltered from hard frosts by being covered with mats. They should also have a light dry soil, otherwise their roots are apt to rot. The species are propagated by seeds, and the particular varieti-

by dividing their roots. The root of the cyclamen has, when fresh, an extremely acrimonious taste, which it loses upon being dried.

CYCLAS, a genus of the decandria monogynia class and order. The cal. is four-parted; cor. none; filaments inserted in the neck of the style, flexuose; legume roundish, winged, one-seeded. There are two species, trees of Guiana.

Cyclas, a genus of testacea of the class of bivalves; shells somewhat transverse, without a fold on the anterior side: exterior ligament recurved; hinge of three teeth; lateral teeth elongated, lamelliform, and let into a groove in the opposite valve.

This genus contains seven or eight species, mostly inhabiting fresh water pools. Animal acephalous, with two tubes projecting on one side, and on the other, a foot linguiform, or tongue-shaped. According to Geoffroy, it is viviparous: the species most common in Europe is the *cyclas cornea*, which is globous, smooth, horn-coloured, with transverse furrows, size of a large pea, inhabits pools of fresh water. See Plate Nat. Hist. fig. 155.

CYCLE, in chronology, a certain period or series of years, which regularly proceed from the first to the last, and then return again to the first, and circulate perpetually. The most considerable cycles are those of the sun, of the moon, and of the Roman indiction.

The cycle of the sun consists of twenty-eight years, which contain all the possible combinations of the dominical letters, in respect to their successive order, as pointing out the common years and leap-years; so that, after the expiration of the cycle, the days of the month return in the same order to the same days of the week, throughout the next cycle; except that upon every centesimal year which is not a leap-year, the letters must always be removed one place forward, to make them answer to the years of the cycle. For instance, if the year 1800 was a leap-year, as every centesimal year is in the Julian account, the dominical letters would be ED, and C would be the dominical letter of the next year; but as it is a common year in the Gregorian account. D is the dominical letter of 1801, which answers to the eighteenth of the cycle, C to the nineteenth, &c. until the next centesimal year. See Dominical letter.

To find the year of this cycle for any year of the christian æra, add 9 to the current year of Christ, because the cycle commenced nine years before the christian æra, and divide the sum by 28, the quotient will show the number of cycles which have revolved since the beginning of that in which the christian æra commenced; and the remainder, if any, shows the current year of the cycle: but if there be no remainder, it shows that it is the last or twenty-eighth year of the cycle.

Cycle of the moon, or lunar cycle, called also the golden number, is a period of nineteen years, after which the new and full moons return on the same days of the months, only one hour twenty-eight minutes sooner; so that, on whatever days the new and full moon fall this year, they will happen nineteen years hence on the same days of the months, except when a centesimal common year falls within the cycle, which will move the new and full moons a day later in the calender than otherwise they would have fallen; insomuch that a new moon which fell, before the centesimal year, suppose on March 10, will fall nineteen years afterwards on March 11. The number of years elapsed in this cycle is called the prime, from its use in pointing out the day of the new moon, primum lunæ; and the golden number, as deserving to be written in letters of gold.

The golden numbers are those placed in the first column of the calendar, betwixt March 21 and April 18, both inclusive, to denote the days upon which those full moons fall, which happen upon, or next after, March 21, in those years of which they are respectively the golden numbers. See Calendar.

For finding the golden number, add one to the current year of our Lord, because one year of this cycle was elapsed before the christian æra began, and divide by nineteen, the remainder is the current year of this cycle, or the golden number; but if nothing remains, it shows that it is the last year of the cycle, and consequently the golden number is 19.

Cycle of the Roman indiction, is a period of fifteen years, in use among the Romans, commencing from the third year before Christ. This cycle has no connection with the celestial motions; but was instituted, according to Baronius, by Constantine; who, having reduced the time which the Romans were obliged to serve to fifteen years, was consequently obliged, every fifteen years, to impose, or *indicere* according to the Latin expression, an extraordinary tax for the payment of those who were discharged; and hence arose this cycle.

To find the cycle of indiction for any given year, add 3 to the given year, and divide the sum by 15, the remainder is the current year of the cycle of indiction; if there be no remainder, it is the fifteenth or last year of the indiction.

These three cycles multiplied into one another, that is, $28 \times 19 \times 15$, amount to 7980, which is called the Julian period, after which the three foregoing cycles will begin again together. This period had its imaginary beginning 710 years before the creation, according to the common opinion among chronologers concerning the age of the world, and is not yet complete. It is much used in chronological tables. See Chronology.

CYCLOID. The Cycloid is a curve of such importance, that the honour of its invention has been much contested among mathematicians. The French ascribe it to their countryman Robervall; but there is sufficient evidence that he was not the original inventor of it. Torricellus informs us, in a treatise containing a demonstration of one of the properties of this curve, viz. that its area is triple that of the generating circle, and published in 1644, that this curve was known forty-five years before this period, or in 1599, to his master Galileo, and distinguished by the appellation of Cycloid. Besides, Dr. Wallis has discovered among the mathematical works of Bovillus, published at several times between the years 1501 and 1510, that this curve had been considered in his time: and he has also found, that it was known to cardinal Cusanus, who gave an account of it in a copy of his works transcribed in 1451. But its various properties have been gradually discovered; and the method of regulating the motion of a pen-

dulum by this curve, which is the most useful application of it, was the invention of Huygens in the last century.

The cycloid is a curve generated by the motion of any point in the periphery of a circle, whilst the periphery itself revolves on a right line, till that point which touched the line at the beginning of the motion be brought to touch it again.

Let the rolling circle be HFI (Pl. XXXIX. Mis. fig. 29); F the point in the periphery, which at the beginning of the motion touched the line BC in B; and the curve BGC described by that point, whilst it is moving from B to C, will be the cycloid, or trochoid, so called from the manner of its formation. The circle HFI, by the revolution of which the curve is formed, is called the generating circle; the right line BC is the base; the line GA bisecting the base in A is the axis; and G is the vertex: a line OF parallel to the base, and intercepted between the curve and the axis, is an ordinate; and the space included by the curve and base, viz. BGCAB, is the cycloidal space.

The curve BGC is called the primary cycloid, to distinguish it from the protracted cycloid MN, and from the contracted cycloid QR, described by the contemporary motion of the corresponding points p and π, in the circles OpN less, and $O\pi R$ greater, than the circle ODG respectively. The protracted cycloid is applied by Dr. Wallis to the solution of Kepler's problem for dividing the area of an ellipse in a giving ratio, of which an account is given in Keill's Astronomy, Lect. 23 and 24.

We shall now enumerate the chief properties of the common cycloid. (1) The whole base BC (fig. 30), is equal to the periphery of the generating circle; and any part of the base BH is equal to the arc FH of the same circle in the position HFI. (2) Any right line FD intercepted between the curve and the generating circle in the position GAD, where AB is = AC, is equal to the corresponding arc DG of the generating circle. For AB = HFI, and BH = FH. ∴ HA = FI = DG, and HA = FD; FD = DG. (3) The ordinate FO = FD + DO = DG + DO = to the sum of the arc intercepted between the ordinate and the vertex, and its right sine. (4) The line LI drawn parallel to the chord MG, is a tangent to the cycloid in L.

[Draw the ordinate LMN parallel to AB, join MG; put r = the radius of the generating circle AMG, x = NG, y = NL, z = the arc MG, and s = its sine = NM, and by the preceding we have $y = s + z$. the differential of which is $dy = ds + dz$. Draw PR indefinitely near and parallel to LN and Mm parallel to $N\pi$, and suppose Mn an indefinitely small right line at right angles to MO the radius of the circle; that is, $Mn = dz$, $nm = ds$, and $Mm = dx$. Then, since the triangles Mnm, MNO are similar, we have $s : r - x :: dx : ds$, and therefore $ds = \frac{r-x}{s} \times dy$, also $s : r :: dx : dz$; therefore $dz = \frac{dx \times r}{s}$. Now by substitution we obtain $dy = \frac{\overline{r-x} \times \overline{dx}}{s} + \frac{r\,dx}{s} = \frac{\overline{2r-x} \times dx}{s}$, and this substituted for dy in the general expression $\frac{dxy}{dy}$; for the subtangent we have $\frac{sy}{2r-x}$. Now since $2r - x : s :: y$: subtangent, it follows that the tangent LI is parallel to the chord MG. (r)

The semicycloid GC is equal to 2GA, or double of the diameter of the generating circle; and the whole cycloid BGC = 4GA = four times the diameter of the generating circle.

(6) If GX be parallel to BAC, the base of the cycloid, and LX parallel to its axis, GA: the space GXL, terminated by the cycloidal arc GL, and the right lines GX and LX, will be equal to the circular area GMN.

Let Px be parallel to LX; and by what has been shown above, $Pp : Lp :: MN : NG$; $= NG \times Pp = MN \times Lp$, i. e. $Xx \times LX = MN \times N\pi$, or the small space $LXxP$ = the small space $MN\pi n$. Consequently the areas GXL and GMN increasing by equal increments, are equal. Hence, if BY be perpendicular to the base BC at B, and meet GX produced at Y, the space GYBPG will be equal to the semicircle GMA: and the rectangle GABY under the diameter GA and $BA = \frac{1}{2}$ the circumference of the generating circle, will be four times the semicircle GMA; and therefore the area GLBAG = three times the area of the generating semicircle GMA, and the whole cycloidal area BLGCAB will be equal to three times the area of the generating circle GMAT. Also, if GB be drawn, the area intercepted between the cycloid GLB, and the right line GB, will be equal to the semicircle GMA; for the area GLBAG = 3GMA. and the triangle $GBA = \frac{1}{2}GA \times AB$ = the rectangle of the radius and semicircumference = the area of the generating circle GMAT = 2GMA; and therefore GL. BAG — GBA = 3GMA — 2GMA = GMA.

(7) The cycloid is the curve of swiftest descent; or a heavy body, descending by the force of its own gravity, will move from one point of this curve to any other point in less time, than it will move by any other line joining these points.

(8) A body falls through any arc, FG, LG, &c. (fig. 30), of an inverted cycloid, whether it be great or small, in the same time. Hence, if a pendulum be made to vibrate in the arc of a cycloid, all the vibrations will be performed in the same time.

CYCLOPTERUS, the sucker, in ichthyology, a genus belonging to the order of amphibia nantes. The head is obtuse, and furnished with saw-teeth; there are four rays in the gilis; and the belly-fins are connected together in an orbicular form. There are three species:

1. The lumpus, or lump-fish, grows to the length of nineteen inches, and weighs seven pounds. The shape of the body is like that of the bream, deep and very thick, and it swims edge-ways. The back is sharp and elevated; the belly flat, of a bright crimson colour. Along the body there run several rows of sharp and bony tubercles, and the whole skin is covered with small ones. The tail and vent-fins are purple. The pectoral fins are large and broad, almost uniting at their base. Beneath these is the part by which it adheres to the rocks, &c. It consists of an oval aperture, surrounded with a fleshy, muscular, and obtuse substance; edged with many small threaded appendages, which concur as so many claspers. By means of this part it adheres with

vast force to any thing it pleases. As a proof of its tenacity, it has been known, that in flinging a fish of this species into a pail of water, it fixed itself so firmly to the bottom, that on taking the fish by the tail, the whole pail by that means was lifted, though it held some gallons, without once making the fish quit its hold. These fish resort in multitudes during spring to the coast of Sutherland near the Ord of Caithness. The seals which swarm beneath, prey greatly upon them, leaving the skins; numbers of which, thus emptied, float ashore at that season. Great numbers of lump-fish are found in the Greenland seas during the months of April and May, when they resort near the shore to spawn. See Plate XL. Nat. Hist. fig. 156.

2. The liparis takes the name of sea-snail from the soft and unctuous texture of its body, resembling that of the land-snail. It is almost transparent, and soon dissolves and melts away. It is found in the sea near the mouths of great rivers, and has been seen full of spawn in January. The length is five inches: the colour a pale brown, sometimes finely streaked with a darker. Beneath the throat is a round depression of a whitish colour like the impression of a seal, surrounded by twelve small pale yellow tubera, by which probably it adheres to the stones like the other species.

3. C. minor, or the lesser sucking-fish, is found in different parts of the British seas. It is about four inches in length; the skin without scales, slippery, and of a dusky colour. It has also an apparatus for adhering to stones and rocks, similar to the others.

CYDER, or CIDER, an excellent drink made of the juice of apples. In making this drink, it has long been thought necessary in every part of England, to lay the harder cyder fruits in heaps for some time before breaking their pulps; but the Devonshire people have much improved this practice: in other countries the method is, to make these heaps of apples in a house, or under some covering, inclosed on every side; this method has been found defective, because, by excluding the free air, the heat soon became too violent, and a great perspiration ensued, by which, in a short time, the loss of juice was so great as to reduce the fruit to half their former weight, attended with a general rottenness, rancid smell, and disagreeable taste. In the southern parts a middle way has been pursued; to avoid the inconveniences attending the above, they make their heaps of apples in an open part of an orchard; where by means of a free air and less perspiration, the desired maturity is brought about, without any considerable waste of the juices, or decay of the fruit, and entirely free of rankness; and though some apples rot even in this manner, they are very few, and are still fit for use, all continue plump and full of juices, and very much heighten the colour of the cyder, without ill-taste or smell. In pursuing the Devonshire method it is to be observed: first, all the promiscuous kind of apples that have dropped from the trees from time to time, are to be gathered up and laid in a heap by themselves, to be made into cyder after having so lain about ten days; secondly, such apples as are gathered from the tree, having already acquired some degree of maturity, are likewise to be laid in a heap by themselves for about a fortnight; thirdly, the later hard fruit, which are to be left on the trees till the approach of frost is apprehended, are to be lain in separate heaps, where they are to remain a month or six weeks, by which, notwithstanding frost, rain, &c. their juices will receive such a maturation as will prepare them for a kindly fermentation, and which they could not have attained on the trees from the coldness of the season.

It is observable, that the riper and mellower the fruits are at the time of collecting them into heaps, the shorter should be their continuance there; and on the contrary, the harsher, more immature, and harder they are, the longer they should rest. These heaps should be made in an even and open part of the orchard, without any regard to covering from rain, dews, or what else may happen during the apples staying there; and whether they be carried in and broken in wet or dry weather, the effect is all the same. If it should be objected, that during their having lain together in the heaps, they may have imbibed great humidity, as well from the air, as from the ground, rain, dews, &c. which are mixed with their juices; the answer is, that this will have no other effect, than a kindly diluting natural to the fruits, by which means a speedier fermentation ensues, and all heterogeneous humid particles are thrown off. The apples are then ground, and the pumices received in a large open-mouthed vessel, capable of containing as much thereof as is sufficient for one making or one cheese, though it has been a custom to let the pumice remain some hours in the vessel appropriated to contain it: yet this practice is by no means commendable; for if the fruits did not come ripe from the trees, or otherwise matured, the pumice remaining in the vat too long, will acquire such harshness and coarseness from the skins as is never to be got rid of; and if the pumice is of well-ripened fruit, the continuing too long there will occasion it to contract a sharpness that very often is followed with want of spirit and pricking; nay, sometimes it even becomes vinegar, or always continues of a wheyish colour, all which proceeds from the heat of fermentation, that it almost instantly falls into on lying together; the pumice, therefore, should remain not longer in the vat than until there may be enough broken for one pressing, or that all be made into a cheese and pressed the day it is broken.

The stooming or stumming of cyder, is done by burning a match or scent in a clean hogshead, moist from recent rinsing, and racking the cyder on the fret into it. If much on the fret, when the cyder is half-racked into the matched or scented cask, burn another match in each cask, roll and tumble them well about (if there are no lees) for a couple of hours, and then finish the racking. Stum is the rich must of good cyder, blended with the vapour of the burning match or scent, stoomed as above, which prevents its fermenting: and when disposed to fret, must be racked into another cask well matched: if this is neglected, and it once ferments, it is no longer stum, but becomes good cyder. Stum is used to mend declining cyder, make it ferment afresh, and give life and sweetness to it, a kind of reanimation. Boiled cyder makes the best keeping stum.

It would doubtless be a great improvement to many estates to cultivate the land not fit for corn, by planting the proper sorts of apples and pears, for the production of so wholesome and pleasant a beverage as cyder or perry. In the preparation of this very estimable liquor, there is no expense of fuel to brew it; and the labour is but once a year, and when sold it yields a very encouraging profit. The larger quantity there is made together,

the better it succeeds; in large vessels it will keep sound and good for many years. Besides, it is a pursuit in which any gentleman can engage, without being considered as a trader. A man may exercise or amuse himself in any manufacture from the produce of his own land, as a necessary or usual mode of reaping or enjoying that produce, and bringing it advantageously to market; and he shall not be considered as a trader, though he buy necessary ingredients or materials to fit it for the market; for this is the way of enjoying the land in cyder countries: but where the produce of the land is merely the raw materials of a manufacture, and used as such, and not according to the usual mode of enjoying the land; in short, where the produce of the land is an insignificant article, in comparison with the whole expense of the manufacture; there he ought to be considered as a trader, and so the law decides.

The manufacturing of cyder and perry forms a capital branch in fruit countries, and of which the improvement must be considered as of great importance to the public, but particularly so to the inhabitants of those districts were these liquors constitute the common beverage.

Cyder and perry, when genuine, and in high perfection, are excellent vinous liquors, and are certainly far more wholesome than many others which are at present in higher estimation. When the must is prepared from the choicest fruit, and undergoes the exact degree of vinous fermentation requisite to its perfection, the acid and the sweet are so admirably blended with the aqueous, oily, and spirituous principles, and the whole so imbued with the grateful flavour of the rinds and the agreeable aromatic bitter of the kernels, that it assumes a new character; grows lively, sparkling, and exhilarating; and when completely mellowed by time, the liquor becomes at once highly delicious to the palate, and friendly to the constitution; superior, in every respect, to most other English wines; for such (says Dr. Fothergill) would it be pronounced by all competent judges, was it not for the popular prejudice annexed to it, as a cheap home-brewed liquor, and consequently within the reach of the vulgar. To compare such a liquor with some of the foreign, fiery, sophisticated mixtures, sometimes imported, would be no credit to it; for it certainly surpasses them in flavour and pleasantness, as much as it excels them in cheapness: but rarely do we meet with perry or cyder of this superior quality; for what is generally sold by dealers and inn-keepers, is a poor, meagre, vapid liquor, disposed to the acetous fermentation, and, of course, very injurious to the constitution. It is very mortifying, after the experience of so many centuries, that the art of preparing those liquors should still be so imperfectly understood as to seem to be in their very infancy; that, throughout the principal cyder districts, the practice should still rest on the most vague undeterminate principles; and that the excellence of the liquor should depend rather on a lucky accident than on good management: yet such appears to be really the case, even amongst the most experienced cyder-makers.

Mr. Marshall, that nice observer of rural affairs, in his late tour through Herefordshire and Gloucestershire, (expressly undertaken for the purpose of inquiry on this subject), informs us, that scarcely two of the professional makers are agreed as to the management of some of the most essential parts of the process; that palpable errors are committed, as to the time and manner of gathering the fruit, in laying it up, in neglecting to separate the unsound and to grind properly the rinds, kernels, &c. that the method of conducting the vinous fermentation, the most critical part of the operation, and which stamps the future value of the liquor, is by no means ascertained; for while some promote the fermentation in a spacious open vat, others repress it, by inclosing the liquor in a hogshead, or strive to prevent it altogether; that no determinate point of temperature is regarded, and that the use of the thermometer is unknown or neglected; that they are as little consistent as to the time of racking off, and whether this ought to be done only once, or five or six times repeated; that for fining down the liquor many have recourse to that odious article bullock's blood, when the intention might be much better answered by whites of eggs or isinglass; and finally, that the capricious taste of particular customers is generally consulted, rather than the real excellence of the liquor; and consequently that a very imperfect liquor is often vended, which tends to reduce the price, to disgrace the vender, and to bring the use of cyder and perry into disrepute.

The art of making vinous liquors is a curious chemical process: and its success chiefly depends on a dextrous management of the vinous fermentation, besides a close attention to several minute circumstances, the theory of which is not, perhaps, yet fully understood by the ablest chemists.

The general method of preparing cyder and perry is very much the same. The mill is not essentially different from that of a common tanner's mill for grinding bark: it consists of a mill-stone from two feet and a half to four and a half in diameter, running on its edge on a circular stone-trough, from nine to twelve inches in thickness, and from one to two tons in weight: the bottom of the trough in which this stone runs is somewhat wider than the thickness of the stone itself; the inner side of the groove rises perpendicularly, but the outer is bevelled in such a manner as to make the top of the trough six or eight inches wider than the bottom, by which means there is room for the stone to run freely, and likewise for putting in the fruit, and stirring it up while grinding. The bed of a middle-sized mill is about nine feet, some ten, and some twelve; the whole being composed of two, three, or four stones, cramped together, and finished after being cramped in this manner: the best stones are found in the forest of Dean, generally a dark-reddish gritstone, not calcareous; for if it was of a calcareous quality the acid juice of the fruits would act upon it and spoil the liquor; a clean-grained grindstone grit is the fittest for the purpose. The runner is moved by means of an axle passing through the centre, with a long arm reaching without the bed of the mill, for a horse to draw by; on the other side is a shorter arm, passing through the centre of the stone, as represented in the figure. An iron bolt, with a large head, passes through an eye in the lower part of the swivel, on which the stone turns into the end of the inner arm of the axis; and thus the double motion of it is obtained, and the stone kept perfectly upright. There ought also to be fixed on the inner arm of the axis, about

a foot from the runner, a cogged wheel, working in a circle of cogs fixed upon the bed of the mill; the use of these is to prevent the runner from sliding, which it is apt to do when the mill is full; it likewise makes the work more easy for the horse: these wheels ought to be made with great exactness. Mr. Marshall observes, that it is an error to make the horse draw by traces. "That acting point of draught (says he), the horse's shoulders, ought, for various reasons, to be applied immediately at the end of the arm of the axis; not two or three yards before it, perhaps in a small mill near one-fourth of its circumference." The building in which the mill is inclosed ought to be of such a size that the horse may have a path of three feet wide betwixt the mill and the wall, so that a middling-sized mill, with its horse-path, takes up a space of fourteen or fifteen feet every way. The whole dimensions of the mill-house, according to our author, to render it any way convenient, are twenty-four feet by twenty; it ought to have a floor thrown over it at the height of seven feet, with a door in the middle of the front, and a window opposite, with the mill on one side and the press on the other side of the window: the latter must be as near the mill as convenience will allow, for the more easy conveying the ground fruit from the one to the other. The press, of which the principle will be understood from the figure, has its bed or bottom about five feet square: this ought to be made entirely either of wood or of stone, the practice of covering it with lead being now universally known to be pernicious. It has a channel cut a few inches within its outer edges, to catch the liquor as it is expressed, and convey it to a lip formed by a projection on that side of the bed opposite the mill; having under it a stone trough or wooden vessel, sunk within the ground, when the bed is fixed low, to receive it. The press is worked with levers of different lengths, first a short, and then a moderately long one, both worked by hand; and lastly, a bar, eight or nine feet long, worked by a capstan or windlass. The expense of fitting up a mill-house is not very great. Mr. Marshall computes it from twenty to twenty-five pounds, and on a small scale from 10 to 15 pounds, though much depends on the distance and carriage of the stone: when once fitted up it will last many years.

The making of the fruit-liquors under consideration requires an attention to the following particulars:

I. The fruit. II. The grinding. III. Pressing. IV. Fermenting. V. Correcting. VI. Laying up. VII. Bottling. Each of these heads is subdivided into several others.

I. In the management of the fruit, the following particulars are to be considered:

1. The time of gathering;—which varies according to the nature of the fruit. The early pears are fit for the mill in September; but few apples are ready for gathering before Michaelmas; though, from accidental circumstances, they are frequently manufactured before that time; for sale cyder and keeping drink, they are suffered to hang upon the trees till fully ripe; and the middle of October is generally looked upon to be a proper time for gathering the stire apples. The criterion of a degree of ripeness is, the fruit falling from the tree: and to force it away before that time, in Mr. Marshall's opinion, is robbing it of some of its most valuable properties; "the harvesting of fruit (says he) is widely different in this respect from the harvesting of grain, which has the entire plant to feed it after the separation from the soil; while fruit, after it is severed from the tree, is cut off from all possibility of a further supply of nourishment; and although it may have reached its wonted size, some of its more essential particles are undoubtedly left behind in the tree." Sometimes, however, the fruits which are late in ripening are apt to hang on the tree until spoiled by frosts, though weak watery fruits seem to be most injured in this manner; and Mr. Marshall relates an instance of very fine liquor being made from golden pippins, after the fruit had been frozen as hard as ice.

2. The method of gathering. This, as generally practised, is directly contrary to the principles laid down by Mr. Marshall, viz. beating them down with long slender poles. An evident disadvantage of this method is, that the fruit is of unequal ripeness: for the apples on the same tree will differ many days, perhaps even weeks in their time of coming to perfection, whence some part of the richness and flavour of the fruit will be effectually and irremediably cut off. Nor is this the only evil to be dreaded; for as every thing depends on the fermentation it has to undergo, if this is interrupted, or rendered complex by a mixture of ripe and unripe fruits, and the liquor is not, in the first instance, sufficiently purged from its feculencies, it is difficult to clear it afterwards. The former defect the cyder-makers attempt to remedy, by a mixture of brown sugar and brandy, and the latter by bullock's blood and brimstone; but neither of these can be expected to answer the purpose very effectually. The best method of avoiding the inconveniences arising from an unequal ripening of the fruit is, to go over the trees twice, once with a hook when the fruit begins to fall spontaneously; the second time when the latter are sufficiently ripened, or when the winter is likely to set in, when the trees are to be cleared with the poles as above-mentioned.

3. Maturing the gathered fruit. This is usually done by making it into heaps, as has been already mentioned: but Mr. Marshall entirely disapproves of the practice; because, when the whole are laid in a heap together, the ripe fruit will begin to rot before the other has arrived at that degree of artificial ripeness which it is capable of acquiring. "The due degree of maturation of fruit for liquor," he observes, "is a subject about which men, even in this district, differ much in their ideas. The prevailing practice of gathering into heaps until the ripest begin to rot, is wasting the best of the fruit, and is by no means an accurate criterion. Some shake the fruit, and judge by the rattling of the kernels; others cut through the middle, and judge by their blackness: but none of these appear to be a proper test. It is not the state of the kernels, but of the flesh; not of a few individuals, but of the greater part of the prime fruit; which renders the collective body fit or unfit to be sent to the mill; the most rational test of the ripeness of the fruit is, that of the flesh having acquired such a degree of mellowness, and its texture such a degree of tenderness, as to yield to moderate pressure; thus, when the knuckle or the end of the thumb can with moderate exertion be forced into

de-pulp of the fruit, is deemed in a fit state for grinding.

4. Preparation for the mill. The proper management of the fruit is to keep the ripe and unripe fruit separate from each other; but this cannot be done without a considerable degree of labour; for as, by numberless accidents, the ripe and unripe fruit are frequently confounded together, there cannot be any effectual method of separating them except by hand; and Mr. Marshall is of opinion, that this is one of the grand secrets of cyder-making, peculiar to those who excel in the business; and he is surprised that it should not before this time have come into common practice.

5. Mixing fruit for liquor. Our author seems to doubt the propriety of this practice; and informs us, that the finer liquors are made from select fruits; and he hints, that it might be more proper to mix liquors after they are made, than to put together the crude fruits.

II. Grinding, and management of the fruit when ground.—For the greater convenience of putting fruit into the mill, every mill should have a fruit-chamber over it, with a trap-door to lower the fruit down into the mill. The best manner in which this can be accomplished is to have the valve over the bed of the mill, and furnished with a hose or tunnel reaching down to the trough in which the stone moves; no straw is used in the lofts, but sometimes the fruit is turned. In Herefordshire it is generally believed, that grinding the rinds and seeds of the fruit as well as the fleshy part to a pulp, is necessary towards the perfection of the cyder, whence it is proper that every kind of pains should be taken to perform the grinding in the most perfect manner. Mr. Marshall complains, that the mills are so imperfectly finished by the workmen, that for the first years they cannot perform their work in a proper manner. Instead of being nicely fitted to one another with the square and chisel, they are hewn over with a rough tool, in such a careless manner that horse-beans might lie in safety in their cavities. Some even imagine that to be an advantage, as if the fruit was more effectually and completely broken by rough than smooth stones. Some use fluted rollers of iron, but these will be corroded by the juice, and thus the liquor might be tinged. Smooth rollers will not lay hold of the fruit sufficiently to force it through.

Another improvement requisite in the cyder mills, is to prevent the matter in the trough from rising before the stone in the last stage of grinding, and a method of stirring it up in the trough more effectually than can be done at present. To remedy the former of these defects, it might perhaps be proper to grind the fruit first in the mill to a certain degree; and then put it between two smooth rollers to finish the operation in the most perfect manner. It is an error to grind too much at once, as this clogs up the mill, and prevents it from going easily. The usual quantity for a middle-sized mill is a bag, containing four corn-bushels; but our author had an opportunity of seeing a mill in which only half a bag was put, and thus the work seemed to go on more easily and more quickly than when more was put in at once. The quantity put in at one time is to be taken out when ground. The usual quantity of fruit ground in a day is as much as will make three hogsheads of perry or two of cyder.

Management of the ground fruit. Mr. Marshall condemns in very strong terms the practice of pressing the pulp of the fruit as soon as the grinding is finished, because thus neither the rind nor seeds have time to communicate their virtues to the liquor, or to extract these virtues in the most proper manner; some allow the ground fruit to lie twenty-four hours or more after grinding, and even regrind it, in order to have, in the most perfect manner, the flavour and virtues of the seeds and rind.

III. Pressing the fruit, and management of the residuum. This is done by folding up the ground fruit in pieces of hair-cloth, and piling them up above one another, in a square frame or mould, and then pulling down the press upon them, which squeezes out the juice, and forms the matter into thin and almost dry cakes. The first runnings come off foul and muddy, but the last, especially in perry, will be as clear and fine as if filtred through paper. It is common to throw away the residuum as useless; sometimes it is made use of, when dry, as fuel; sometimes the pigs will eat it, especially when not thoroughly squeezed; and sometimes it is ground a second time with water, and pressed for an inferior kind of liquor used for the family. Mr. Marshall advises to continue the pressure as long as a drop can be drawn. "It is found (says he) that even by breaking the cakes of the refuse with the hands only, gives the press fresh power over it: for, though it has been pressed to the last drop, a gallon or more of additional liquor may be got by this means: regrinding them has a still greater effect; in this state of the materials, the mill gains a degree of power over the more rigid parts of the fruits, which in the first grinding it could not reach. If the face of the runner, and the bottom of the trough, were dressed with a broad chisel, and made true to each other, and a moderate quantity of residuum ground at once, scarcely a kernel would escape unbroken, or a drop of liquor remain undrawn."

But though the whole virtue of the fruit cannot be extracted without grinding it very fine, some inconveniences attend this practice, as a part of the pulp thus gets through the hair-cloth, and may perhaps be injurious to the subsequent fermentation. This, however, may be in a great measure remedied by straining the first runnings through a sieve: the whole should also be allowed to settle in a cask, and drawn off into a fresh vessel previous to the commencement of the fermentation. The reduced fruit ought to remain some time between the grinding and pressing, that the liquor may have an opportunity of forming an extract with the rind and kernels; but this must not be pushed too far, as in that case the colour of the cyder would be hurt; and the most judicious managers object to the pulp remaining longer than twelve hours without pressure: "thence (says our author) upon the whole, the most eligible management in this stage of the process appears to be this: grind one press-full a day; press, and regrind the residuum in the evening; infuse the reduced matter all night among part of the first runnings, and in the morning repress while the next press-full is grinding."

IV. Fermentation. The common practice is, to have the liquor tunned, that is, put into casks or hogsheads, immediately from the press, and to fill them quite full; but it is undoubtedly more proper to leave some space empty to be filled up afterwards. No accurate experiment has been made with regard to the temperature of the air proper to be kept up in the place where the fermentation goes on.

Frost is prejudicial; but when the process usually commences, that is, about the middle of October, the liquor is put into airy sheds, where the warmth is scarcely greater than in the open atmosphere; nay, it is frequently exposed to the open air without any covering farther than a piece of tile or flat stone over the bung-hole, propped up by a wooden pin on one side to cause the rain-water to run off. In a complete manufactory of fruit liquor, the fermenting room should be under the same roof with the mill-house, a continuation of the press-room, or at least opening into it with windows or doors on every side, to give a free admission of air into it, with sufficient defence against frost; fruit-lofts over it, and vaults underneath, for laying up the liquors after fermentation, with small holes in the crown of the arch to admit a hose or pipe for the purpose of conveying the liquors occasionally from the one to the other.

In making of fruit-liquors no ferment is used, as in making of beer; though, from Mr. Marshall's account of the matter, it seems far from being unnecessary. Owing to this omission, the time of the commencement of the fermentation is entirely uncertain; it takes place sometimes in one, two, or three days, sometimes not in a week or a month, after tunning; but it has been observed, that liquor which has been agitated in a carriage, though just taken from the press, will sometimes pass almost immediately into a state of fermentation. The continuance of the fermentation is no less uncertain than the commencement of it. Liquors, when much agitated, will go through it perhaps in one day; but when allowed to remain at rest, the fermentation commonly goes on two or three days, and sometimes five or six. The fermenting liquor, however, puts on a different appearance according to circumstances; when produced from fruits properly matured, it generally throws up a thick scum, resembling that of malt liquor, and of a thickness proportioned to the species and ripeness of the fruit; the riper the fruit, the more scum is thrown up. Perry gives but little scum, and cyder will also sometimes do the same: sometimes it is intentionally prevented from doing it.

After having remained some time in the fermenting-vessel, the liquor is racked or drawn off from the lees, and put into fresh casks. In this part of the operation also Mr. Marshall complains greatly of the little attention that is paid to the liquor. The ordinary time for racking perry is before it has done hissing, or sometimes when it begins to emit fixed air in plenty. The only intention of the operation is, to free the liquor from its fæculencies, by a cork placed at a little distance from the bottom, after which the remainder is to be filtred through a canvass or flannel bag; this filtred liquor differs from the rest in having a higher colour, having no longer any tendency to ferment, but, on the contrary, checking the fermentation of that which is racked off; and if it loses its brightness, it is no longer easily recovered. A fresh fermentation usually commences after racking, and if it becomes violent, a fresh racking is necessary in order to check it, in consequence of which the same liquor will be racked off five or six times: but if only a small degree of fermentation takes place, which is called fretting, it is allowed to remain in the same cask, though even here the degree of fermentation which requires racking is by no means determined. Mr. Marshall informs us, that the best manufacturers, however, repeat the rackings until the liquor will lie quiet, or nearly so; or if it be found impracticable to accomplish this by the ordinary method of fermentation, recourse must be had to fumigation with sulphur, which is called stumming the casks. For this fumigation, it is necessary to have matches made of thick linen-cloth, about ten inches long, and an inch broad, thickly coated with brimstone for about eight inches of their length. The cask is then properly seasoned, and every vent, except the bung-hole, tightly stopped; a match kindled is lowered down into the cask, and held by the undipped end until it is well lighted, and the bung driven in; thus suspending the lighted match within the cask. Having burnt as long as the contained air will supply the fire, the match dies, the bung is raised, the remnant of the match drawn out, and the cask suffered to remain before the liquor is put into it for two or three hours, more or less, according to the degree of power the sulphur ought to have. The liquor retains a smell of the sulphureous acid; but this goes off in a short time, and no bad effect is ever observed to follow.

In some places the liquor is left to ferment in open casks, in which it stands till the first fermentation is pretty well over; after which the froth or yeast collected upon the surface is taken off, it being supposed that it is this yeast mixing with the clear liquor which causes it to fret after racking. The fermentation having totally ceased, and the lees subsided, the liquor is racked off into a fresh cask, and the lees filtred, as above directed. Our author mentions a way of fermenting fruit-liquors in broad shallow vats, not less than five feet in diameter, and little more than two feet deep, each vat containing about two hogsheads. In these the liquor remains until it has done rising, or till the fermentation has nearly ceased; when it is racked off without skimming, the critical juncture being caught before the yeast falls, the whole sinking gradually together as the liquor is drawn off. In this practice also the liquor is seldom drawn off a second time.

Cyder is made of three different kinds, viz. rough, sweet, and of a middle richness. The first kind, being usually destined for common use, is made with very little ceremony; if it is but *cyder* (says Mr. Marshall), and has body enough to keep, no matter for the richness and flavour. The rougher it is the further it will go; and the more acceptable custom has rendered it, not only to the workmen but to their masters. A palate accustomed to sweet cyder, would judge the rough cyder of the farm-house to be a mixture of vinegar and water, with a little dissolved alum to give it roughness. The method of producing this austere liquor is, to grind the fruit in a crude under-ripe

state, and subject the liquor to a full fermentation; for the sweet liquor, make choice of the sweeter fruits, mature them fully, and check the fermentation of the liquor. To produce liquors of a middle richness, the nature of the fruit, as well as the season in which it is matured, must be considered. The fruits to be made choice of are such as yield juices capable of affording a sufficiency both of richness and strength; though much depends on a proper management. Open vats, in our author's opinion, are preferable to close vessels; but if casks are used at all, they ought to be very large, and not filled; nor ought they to lie upon their sides, but to be set on their ends, with their heads out, and to be filled only to such a height as will produce the requisite degree of fermentation; but in whatever way the liquor be put to ferment, Mr. Marshall is of opinion that the operation ought to be allowed to go on freely for the first time, though after being racked off any second fermentation ought to be prevented as much as possible.

V. Correcting, provincially called doctoring. The imperfections which art attempts to supply in these liquors are, 1. Want of strength. 2. Want of richness. 3. Want of flavour. 4. Want of colour and brightness.

The want of strength is supplied by brandy, or any other spirit, in sufficient quantity to prevent the acetous fermentation. The want of richness is supplied by what are generally termed sweets, but prepared in a manner which our author says has never fallen within his notice. To supply the want of flavour, an infusion of hops is sometimes added, which is said to communicate an agreeable bitter, and at the same time a fragrance; whence it becomes a substitute for the juices of the rinds and kernels thrown away to the pigs and poultry, or otherwise wasted. The want of colour is sometimes supplied by elder-berries, but more generally by burnt sugar, which gives the desired colour, and a degree of bitter which is very much liked; the sugar is prepared either by burning it on a salamander, and suffering it to drop as it melts, or by boiling it over the fire (in which case brown sugar is to be used) until it acquires an agreeable bitter, then pouring in boiling water in the proportion of a gallon to two pounds of sugar, and stirring it until the liquor becomes uniform: a pint of this preparation will colour a hogshead of cyder. Brightness is obtained by a mixture of the blood of bullocks or sheep, that of swine being rejected, though it does not appear to be more unfit for the purpose than either of the other two; the only thing necessary to be done here is, to stir the blood well as it is drawn from the animal, to prevent the parts from separating, and it ought to be stirred both ways for a quarter of an hour: the liquor, however, is not always in a proper condition for being refined with this ingredient, on which account a little of it ought frequently to be tried in a phial: a quart, or less, will be sufficient for a hogshead. After the blood is poured in, the liquor should be violently agitated, to mix the whole intimately together: this is done by a stick slit into four, and inserted into the bung-hole, working it briskly about in the liquor until the whole be thoroughly mixed; in about 24 hours the blood will have subsided, and the liquor ought instantly to be racked off, as by remaining upon the blood even for two or three days, it will receive a taint not easily to be got rid of. It is remarkable that this refinement with the blood carries down not only the fæculencies, but the colour also, rendering the liquor, though ever so highly coloured before, almost as limpid as water. Isinglass and eggs are sometimes made use of in refining cyder as well as wine.

VI. Laying up, or shutting up the cyder in close casks, according to Mr. Marshall, is as little understood as any of the rest of the parts; the bungs being commonly put in at some certain time, or in some particular month, without any regard to the state the liquor itself is in. "The only criterion (says he) I have met with for judging the critical time for laying up, is when a fine white cream-like matter first begins to form upon the surface. But this may be too late; it is probably a symptom at least of the acetous fermentation, which, if it take place in any degree, must be injurious: yet if the cask be bunged tight some criterion is necessary; otherwise if the vinous fermentation have not yet finally ceased, or should recommence, the casks would be endangered, and the liquor injured. Hence, in the practice of the most cautious manager, whose practice I have had an opportunity of observing, the bungs are first driven in lightly, when the liquor is fine, and the vinous fermentation is judged to be over; and some time afterwards, when all danger is past, the casks are filled up, and the bung driven securely with a rag, and both rosined over at top. Most farmers are of opinion, that after the liquor has done fermenting, it ought to have something to feed upon; that is, to prevent it from running into the acetous fermentation. For this purpose some put in parched beans, others egg-shells, some mutton-suet," &c. Mr. Marshall does not doubt that something may be useful, and thinks that isinglass may be as proper as any thing that can be got.

VII. Bottling. This depends greatly on the quality of the liquors themselves: good cyder can seldom be bottled with propriety until a year old; sometimes not till two. The proper time is, when it has acquired the utmost degree of richness and flavour in the casks; and this it will preserve for many years in bottles. It ought to be quite fine at the time of bottling, or if not so naturally, ought to be fined artificially with isinglass and eggs.

The liquor called cyderkin, purre, or perkin, is made of the mark, or gross matter remaining after the cyder is pressed out. To make this liquor, the mark is put into a large vat, with a proper quantity of boiled water, which has stood till it is cold again; if half the quantity of water is used that there was of cyder, it will be good; if more, the cyderkin will be small. The whole is left to infuse 48 hours, and then well pressed: what is squeezed out by the press is immediately tunned up and stopped; it is fit to drink in a few days. It clarifies of itself, and serves in families instead of small beer. It will keep, if boiled after pressing with a convenient quantity of hops.

We must not conclude this subject without particular notice of the liquor called cyder-wine, which is made from the juice of the apples taken from the press and boiled; and which, being kept three or four years, is said to resemble rhenish. The method of preparing this wine, as communicated by Dr. Rush, consists in evaporating in a brewing-copper the fresh apple-juice, till half of it is wasted; the remainder is then immediately conveyed into a wooden cooler, and afterwards put into a proper cask, with

an addition of yeast: and is fermented in the ordinary way. The process has been evidently borrowed from what has long been practised on the recent juice of the grape, under the term of vina cotta, or boiled wine, not only in Italy, but also in the islands of the Archipelago from time immemorial.

This process has lately become an object of imitation in the cyder countries, and particularly in the west of England, where it is asserted, that many hundred hogsheads of this wine have been already made; and it is said to betray no sign of an impregnation of copper by the usual chemical tests; it is considered as perfectly wholesome, and is accordingly drunk without apprehension by the common people. Others, however, suspect its innocence; whence it appeared an object of no small moment to determine, in so doubtful a matter, whether or not the liquor acquires any noxious quality from the copper in which it is boiled. With this view Dr. Fothergill made a variety of experiments, and the result seemed to afford a strong presumption that the cyder-wine does contain a minute impregnation of copper, not very considerable indeed, but yet sufficient, in the doctor's opinion, to put the public on their guard concerning a liquor that comes in so very questionable a shape.

In the present process the liquor is properly directed to be passed into a wooden cooler as soon as the boiling is completed. But as all acids, and even common water, acquire an unpleasant taste from standing in copper vessels in the cold, why may not the acid juice of apples act in some degree on the copper before the boiling commences? Add to this, that brewing coppers, without far more care and attention than is generally bestowed on them in keeping them clean, are extremely apt to contract verdigris (a real poison), as appears from the blue or green streaks very visible when these vessels are minutely examined; should the unfermented juice be thought incapable of acting on the copper either in a cold or boiling state, yet no one will venture to deny its power of washing off, or dissolving, verdigris already formed on the internal surface of the vessel. Suppose only one-eighth part of a grain of verdigris to be contained in a little of this wine,* a quantity that may elude the ordinary tests, and that a bottle should be drunk daily by a person without producing any violent symptom of internal uneasiness; yet what person in his senses would knowingly choose to hazard the experiment of determining how long he could continue even this quantity of slow poison, in his daily beverage, with impunity? And yet, it is to be feared, that the experiment is but too often unthinkingly made, not only with cyder-wines, but also with many of the foreign wines prepared by a similar process; for the grape-juice, when evaporated in a copper vessel, under the denomination of vina cotta, or boiled wine, cannot but acquire an equal, if not yet stronger, impregnation of the metal, than the juice of apples: since verdigris itself is manufactured merely by the application of the acid husks of grapes to plates of copper.

Perry is a most wholesome pleasant liquor of the cyder kind, some of which is so excellent as to pass for champaign in taverns and other places of public resort: indeed more wines than this have been imitated with cyder and perry, particular by the Hollanders, and sometimes by the Flemings. Dr. Halley observes, that the London market alone took off upwards of 20,000 hogsheads of Devonshire cyder annually. It was in the year 1721 he made this remark, and then suggested it was not all sold as cyder. Whether the demand has increased we cannot say. We have drunk in Flanders some perry that might pass on ordinary judges for mantling champaign. Perry is prepared from pears in the same manner cyder is from apples. The harsher sorts of pears make the best perry. They are infinitely too harsh and acerb, or tart, for eating, so much so that even hungry swine reject them. The most esteemed for the purpose are the Bosbury pear, the Bauland and the horse pear in Worcestershire, and the squash pear, as it is called, in Gloucestershire; in both which counties, as well as in some of the adjacent parts, they are planted in the hedgerows, and most common fields. There is this advantage attending pear-trees, that they will thrive on land where apples will not so much as live; and that some of them grow to such a size, that a single pear-tree, particularly of the Bosbury and the squash kinds, has been frequently known to yield in one season from one to four hogsheads of perry. The Bosbury pear is thought to yield the most lasting and most vinous liquor. The John-pear, the Harpary-pear, the drake-pear, Mary-pear, the Lullum-pear, and several others of the barshest kind, are esteemed the best for perry; and the redder or more tawny they are, the more they are preferred. Pears as well as apples should be fully ripe before they are ground. Crab-apples are frequently mixed with the pears, and are said to improve the perry.

CYGNUS, in astronomy, a constellation of the northern hemisphere, consisting of 17 stars according to Ptolemy's catalogue, of 19 in Tycho's, and in the Britannic catalague of 107.

CYLINDER, in geometry, a solid body, supposed to be generated by the rotation of a parallelogram. See GEOMETRY.

CYLINDER, *properties of the.* 1. The section of every cylinder by a plane oblique to its base is an ellipsis. 2. The superficies of a right cylinder is equal to the periphery of the base multiplied into the length of its side. 3. The solidity of a cylinder is equal to the area of its base multiplied into its altitude. 4. Cylinders of the same base, and standing between the same parallels, are equal. 5. Every cylinder is to a spheroid inscribed in it as 3 to 2. 6. If the altitudes of two right cylinders be equal to the diameters of their bases, those cylinders are to one another as the cubes of the diameters of their bases.

To find a circle equal to the surface of a cylinder we have this theorem: the surface of a cylinder is equal to a circle whose radius is a mean proportional between the diameter and height of the cylinder. The diameter of a sphere, and altitude of a cylinder equal thereto, being given, to find the diameter of the cylinder, the theorem is: the square of the diameter of the sphere is to the square of the diameter of the cylinder equal to it, nearly as triple the altitude of the cylinder to double the diameter of the sphere.

* The one-hundredth part of a grain may be discovered in a quart, by adding a few drops of volatile alkali to a glass-full, which will immediately strike a blue, darker or lighter, in proportion to the impregnation, a quantity too minute to do any injury.

CYLINDER, *resistance of.* See the article RESISTANCE.

CYLINDER, *rolling*, or *loaded*, in philosophy, a cylinder which rolls up an inclined plane. See MECHANICS.

CYLISTA, a genus of the class and order diadelphia decandria. The calyx is large, four-parted, upper division cleft at the end; corolla permanent. There is one species.

CYMATIUM, in architecture, a member or moulding of the cornice, the profile of which is waved, that is, concave at the top, and convex at bottom.

CYMBACHNE, a genus of the class and order polygamia monœcia. The inflorescence is half-spiked. There is one species, a grass of Bengal.

CYMBAL, or *cymbalum*, a musical instrument of antiquity, similar to the tympanum or drum. The cymbal was round, and made of brass, like our kettle-drums; but is generally thought to have been smaller. The Jews had their cymbals, or instruments which translators render by that name. Ovid gives cymbals the epithet genialia, because they were used at weddings.

CYMBARIA, a genus of the class and order didynamia angiospermia. The calyx is ten-toothed; capsule cordate, two-celled. There is one species, an herbaceous plant of the mountains of Dauria.

[CYMBIDUM, in botany, a genus of the order monandria, in the gynandria class of plants. The corolla is five petalled, erect; the capsule one celled, oblong. There are four species, all natives of Pennsylvania: 1. the C. pulchellum, or tuberous cymbidium, flowers in July; 2. the C. hyemale, or winter green, flowers in May; 3. the C. odontorhizon, or large tooth-rooted, flowers in September; 4. the corallorhizon small coral-rooted, flowers in August. (*b*)

CYMOPHANE, the oriental chrysolite of jewellers. This stone has been found only in Brazil, the island of Ceylon, and at North-schink in Siberia. It is usually met with in round masses about the size of a pea, but it is sometimes crystallized. The primitive form of its crystals is a four-sided rectangular prism, the height of which is to the breadth as $\sqrt{3}$ to 1, and to its thickness as $\sqrt{2}$ to 1. The most common variety is an eight-sided prism, terminated by six summits. Two of the faces of the prism are hexagons, two are rectangles, and four trapezia: two faces of the summits are rectangles, and the other four trapezia. Sometimes two of the edges of the prism are wanting, and small faces in their place. Its texture is foliated: it causes double refraction. Its specific gravity from 3.7 to 3.8. The colour yellowish-green, surface sparkling. It is infusible by the blow-pipe per se, and also with soda. By analysis it is found by Klaproth to contain,

71.5	alumina,
18.0	silica,
6.0	lime,
1.5	oxide of iron.
97.0	

CYNANCHE, among physicians, denotes an inflammation of the larynx. See MEDICINE.

CYNANCHUM, *bastard dogsbane*, a genus of the digynia order, in the pentandria class of plants, and in the natural method ranking under the 30th order, contortæ. The nectarium is cylindrical and quinquedentated. There are 27 species, of which the following are the most remarkable:

1. The acutum, commonly called Montpellier scammony; and,

2. The monspeliacum, or round-leaved Montpellier scammony. They abound with a milky juice like the spurge, which issues out wherever they are broken; and this milky juice when concreted has frequently been sold for scammony. These plants propagate so fast by their creeping roots, that few people care to admit them into their gardens.

CYNARA, the *artichoke*, a genus of the polygamia æqualis order, in the syngenesia class of plants. The calyx is dilated, imbricated with carnous squamæ and emarginated with a sharp point. Of this genus there are six species, but only two are cultivated for use.

1. The scolymius, or garden artichoke, has large, thick, perennial roots, crowned by a considerable cluster of large, pinnatifid, erect leaves. In the middle are upright stalks rising a yard high, on the top of which is a large round scaly head, composed of numerous, oval, calycinal scales, inclosing the florets, sitting on a broad fleshy receptacle, which, with the fleshy base of the scales, is the only eatable part of the plant. The varieties of this species are, 1. The conical green-headed French artichoke, having the small leaves terminated by spines, the head of a light-green colour, with the scales pointed at top, opening, and turning outward. 2. The globular-headed Dutch artichoke, having leaves without spines, a strong stalk, the head large, globular, a little compressed at top, and of a brown colour; broad obtuse scales emarginated at top, growing close, and turning inward. Of these varieties the last is deservedly the most esteemed, both on account of its superiority in size and the agreeableness of its flavour. Both varieties are perennial in their root: but the leaves and fruit-stem die to the ground in winter; and their roots remaining, send up fresh leaves and stems every summer, producing a supply of artichokes for 20 years if required. The flowers and seeds of all the plants of this genus are produced in the centre of the head; the scales of which are the proper calyx of the flower, which consists of numerous small blueish florets, succeeded by downy seeds sitting naked on the receptacle.

2. The cardunculus, or cardoon, greatly resembles the artichoke, but is of large and more regular growth; the leaves being more upright, taller, broader, and more regularly divided; and the stalks of the leaves blanched are the only eatable parts of the plant.

Both the above varieties of the artichoke are propagated by slips or suckers, arising annually from the stool or root of the old plants in spring, which are to be taken from good plants of any present plantation in March, or the beginning of April, and planted in the open quarters of the kitchen-garden, in rows five feet asunder; and they will produce artichokes the same year in autumn. It should, however, be remarked, that though artichokes are of many years duration, the annual produce of their fruit will gradually lessen in the size of the eatable parts after the third or fourth year, so that a fresh plantation should be made every three or four years. The cardoon is a very hardy plant, and pro-

pers in the open quarters of the kitchen-garden. It is propagated by seed sown annually in the full ground in March: either in a bed for transplantation, or in the place where they are designed to remain. The plants are very large, so must stand at considerable distance from one another. By this means you may have some small temporary crops between the rows, as of lettuce, spinach, endive, cabbage, savoy, or brocoli plants. In the latter part of September, or in October, the cardoons will be grown very large, and their footstalks have acquired a thick substance; you must then tie up the leaves of each plant, to admit of earthing them closely all round for blanching, which will take up six or eight weeks; and thus the plants will come in for use in November and December, and continue all winter.

CYNIPS, in zoology, a genus of insects belonging to the hymenoptera order. The mouth is armed with jaws, but has no proboscis: the sting is spiral, and mostly concealed within the body. The quercus folii, or oak-leaf cynips, is of a burnished shining brown colour. It is in the little, smooth, round, hard galls, found under the oak-leaves, generally fastened to the fibres, that this insect is produced, a single one in each gall. These latter are ligneous, of a hard compact substance, formed like the rest by the extravasation of the sap of the leaf, occasioned by the puncture of the gall-fly when it deposits its eggs. Sometimes, instead of the cynips, there is seen to proceed from the gall a large insect of a brown colour, which is an ichneumon. This ichneumon is not the real innate of the gall, or he that formed it. He is a parasite, whose mother deposited her eggs in the yet tender gall; which, when hatched, brings forth a larva that destroys the larva of the cynips, and then comes out when it has undergone its metamorphosis and acquired its wings.

The quercus gemmæ, or oak-bud cynips, is of a very dark green, slightly gilded. It deposits its eggs in oak-buds, and produces one of the finest galls, leafed like a rose-bud beginning to blow. When the gall is small, a great quantity of the leaves is compressed, and they are set upon one another like the tiles of a roof. In the centre of the gall there is a kind of ligneous kernel, in the middle of which is a cavity; and in that is found the little larva, who feeds there, takes its growth, undergoes its metamorphosis, and breaks through the inclosure of that kind of cod in order to get out. The whole gall is often near an inch in diameter, sometimes more when dried; and it holds to a branch by a pedicle. There are 19 species of this insect.

CYNOGLOSSUM, hound's-tongue; a genus of the monogynia order, in the pentandria class of plants; and in the natural method ranking under the 41st order, asperifoliæ. The corolla is funnel-shaped, with its throat closed up by little arches formed in it; the seeds depressed, and fixed to the style of the receptacle only on their inner side. There are 12 species, none of them remarkable for their beauty. The root of one of them, the officinale, or common greater hound's-tongue, was formerly used in medicine, and supposed to possess narcotic virtues; but it is now discarded from practice. The smell of the whole plant is very disagreeable. Goats eat it: sheep, horses, and swine, refuse it.

CYNOMETRA, a genus of the monogynia order, in the decandria class of plants; and in the natural method ranking with those of which the order is doubtful. The calyx is tetraphyllous; the antheræ bifid at top; the legumen carnous, crescent-shaped, and monospermous. There are two species.

CYNOMORIUM, a genus of the monandria order, in the monœcia class of plants; and in the natural method ranking under the 50th order, amentaceæ. The male calix is an imbricated catkin; there is no corolla; the calix of the female is in the same catkin; no corolla; one style; and one roundish seed. There are three species, of no note.

CYNOSORUS, a genus of the digynia order, belonging to the triandria class of plants; and in the natural method ranking under the 4th order, gramina. The calix is bivalved and multiflorous; the receptacle proper, unilateral, and foliaceous. There are 20 species, four of which are natives of Britain, viz. the cristatus, or crested dog-tail grass; the echinatus, or rough dog-tail grass: the cæruleus, or blue dog-tail grass; and the paniceus, or bearded dog-tail grass.

CYPERUS, a genus of the monogynia order, in the triandria class of plants; and in the natural method ranking under the 3d order, calamariæ. The glumes are paleaceous, and imbricated towards each side; the corolla is wanting, and there is one naked seed. There are 53 species; the only remarkable are the round, the long sweet cyperus, and the papyrus. The former is a native of the East Indies, and grows by the sides of rivulets, ditches, &c. The root is knotty, wrapped round with fibrous strings not easy to break, of a brown colour without, and grey within: of a pleasant scent, especially when well dried; the leaves are green, and resemble those of the reed and leek.

2. The long-leaved, commonly called English or Flemish cyperus, grows in the water, and along the banks and river sides. Its root is as thick as an olive, full of little knots or specks, of an oblong figure, grey colour, sweet and somewhat sharp tasted, and almost without smell when it is newly taken out of the ground. The roots of both plants are esteemed cordial and diuretic, and the long cyperus is much used by perfumers and glovers.

3. The papyrus is famous both in ancient and modern history, and a very minute description of it is given by Pliny. It grows in the lakes of Ethiopia and Egypt. It was very early in use as paper, Numa having left a number of books written on papyrus. The paper was made from the pellicle between the pith and the bark. Boats were also made of the whole plant together, a piece of acacia wood being used as a keel. It was also used for cordage. Cups, moulds, &c. were made of the lower part.

CYPRÆA, or *gowrie*, in zoology, a genus of insects belonging to the order of vermes testacea. It is an animal of the limax or snail kind; the shell is one involuted, subovated, obtuse, smooth valve. The aperture on each side is linear, longitudinal, and toothed. There are 44 species, distinguished by the form of their shells. This genus is called cypræa, and venerea, from its being peculiarly dedicated to Venus; who is said to have endowed a shell of this genus with the powers of a remora, so as to impede the course of the ship which was sent by Periander, tyrant of Corinth, with orders to destroy

the young nobility of Corcyra. See Pl. XL. Nat. Hist. fig. 157.

CYPRESS. See CUPRESSUS.

CYPRINUS, in ichtyology, a genus of fishes belonging to the order of abdominales. The mouth is toothless; there are three rays in the gills; the body is smooth and white, and the belly-fins have frequently nine rays. There are 31 species, principally distinguished by the number of rays in the vent-fin. The most remarkable are:

1. The carpio, or carp. This was introduced into England about the year 1514, by Leonard Maschal, to whom they are also indebted for that excellent apple the pepin. Russia wants these fish at this day. Sweden has them only in the ponds of people of fashion. They chiefly abound in the rivers and lakes of Polish Prussia, where they are sometimes taken of a vast size. They are there a great article of commerce, and sent in well-boats to Sweden and Russia. The merchants purchase them out of the waters, of the noblesse of the country, who draw a good revenue from this article.

Carp are very long lived. Gesner brings an instance of one that was near 100 years old. They grow also to a very great size. Some authors speak of carp weighing 200 pounds, and five feet in length. The carp is a prodigious breeder; its quantity of roe has been sometimes found so great, that when taken out and weighed against the fish itself, the former has been found to preponderate. From the spawn of this fish, caviare is made for the Jews, who hold the sturgeon in abhorrence. The carp is extremely cunning, and on that account is sometimes styled the river fox. They will sometimes leap over the nets, and escape that way; at other times they will immerse themselves so deep in the mud as to let the net pass over them. They are also very shy in taking a bait; yet at the spawning-time they are so simple, as to suffer themselves to be tickled, handled, and caught, by any body that will attempt it. This fish is apt to mix its milt with the roe of other fish, from which is produced a spurious breed, as has been observed in the offspring of the carp and tench, which bore the greatest resemblance to the first. The same has also been observed of the carp and bream.

In Polish Prussia, and many other parts of Germany, the sale of carp constitutes a part of the revenue of the nobility and gentry, so that the proper management of that fish is reduced to a kind of system, founded on the experience of several generations. Of the methods there practised, we have an account in the Philosophical Transactions for 1771, communicated by Mr. J. Reinhold Forster; who says he has seen carp treated and maintained according to those methods, "above a yard long, and of 25 pounds weight;" but had no opportunity of ascertaining their age. "In the pond, however, at Charlottenburg, (he adds,) a palace belonging to the king of Prussia, I saw more than two or three hundred carp, between two and three feet long; and I was told by the keeper they were between 50 and 60 years standing. They were tame, and came to the shore in order to be fed." Mr. Forster, in this paper, also vouches for a most extraordinary circumstance, namely, the possibility of the carp's not only living for a considerable time out of water, but of its growing fat in its new element. The author has seen the experiment successfully tried, and attended to the whole process, in a nobleman's house, where he then resided, in the principality of Anholt-Dissau. The fish being taken out of the water, is wrapped up in a large quantity of wet moss, spread on a piece of net, which is then gathered into a purse, in such a manner however as to allow him room to breathe. The net is then plunged into water, and hung up to the ceiling of a cellar. At first the dipping must be repeated every three or four hours, but afterwards the carp need only be plunged into the water once in about six or seven hours. Bread soaked in milk is first given him in small quantities. In a short time, the fish will bear more, and grow fat under this seemingly unnatural treatment. Mr. Daines Barrington, in a note, confirms a part of the preceding account, by mentioning the practice of a certain fishmonger near Clare-market, who, in the winter, frequently exposed a bushel, at least, of carp and tench for sale, in the same dry vessel, for six or seven hours, many of which were not sold, and yet continued in health, though breathing nothing but air during the time above-mentioned, for several days successively.

2. The barbus, or barbel, is so extremely coarse, as to be overlooked by the ancients till the time of the poet Ausonius, who gives it no great character. They frequent the still and deep parts of rivers, and live in society, rooting like swine with their noses in the soft banks. It is so tame as to suffer itself to be taken by the hand; and people have been known to take numbers by diving for them. In summer, they move about during night in search of food; but towards autumn, and during winter, confine themselves to the deepest holes. The barbel is about the length of three feet, and will weigh 18 pounds; the belly white; the dorsal fin is armed with a remarkably strong spine, sharply serrated, with which it can inflict a very severe and dangerous wound on the incautious handler, and even do much damage to nets. They are the worst and coarsest fresh-water fish, and seldom eaten but by the poorer sort of people, who sometimes boil them with a bit of bacon, to give them a relish. Their roe is very noxious, affecting those who unwarily eat of it, with a nausea, vomiting, purging, and a slight swelling.

3. The tinca, or tench, was treated with the same disrespect by the ancients as the barbel; but is now in much more repute. It has by some been called the physician of the fish; and its slime has been said to be of so healing a nature, that the wounded fishes apply it as a styptic. In England it is reckoned a wholesome and delicious food; but the Germans are of a different opinion. By way of contempt, they call it the shoemaker. Gesner even says, that it is insipid and unwholesome. It does not commonly exceed four or five pounds in weight, though some have been known to weigh 10 or 20. They love still waters, and are rarely found in rivers. They are very foolish, and easily caught. The tench is thick, and short in proportion to its length. The colour of the back is dusky; the dorsal and ventral fins of the same colour; the head, sides, and belly, of a greenish cast, most beautifully mixed with gold, which is in its greatest splendour when the fish is in the highest season.

4. The gobio, or gudgeon, is generally found in gen-

de streams, and is of a small size, the largest not exceeding ½ lb. weight. They bite eagerly; and are assembled by raking the bed of the river: to this spot they immediately crowd in shoals, in expectation of food.

5. The brama, or bream, is an inhabitant of lakes, or the deep parts of still rivers. It is a fish that is very little esteemed, being extremely insipid.

6. The rutilus, or roach, is a common fish, found in many of the still deep rivers. They are gregarious, keeping in large shoals. It has never been known to exceed five pounds in weight.

7. The leuciscus, or dace, like the roach, is gregarious, haunts the same place, is a great breeder, very lively, and during summer is very fond of frolicking near the surface of the water. It never exceeds the weight of a pound and a half; the scales are smaller than those of the roach.

8. The cephalus, or chub, is a very coarse fish, and full of bones. It frequents the deep holes of rivers, and in summer commonly lies on the surface beneath the shade of some tree or bush. It is very timid, sinking to the bottom on the least alarm, even at the passing of a shadow; but it will soon resume its former situation. It feeds on worms, caterpillars, grasshoppers, and other coleopterous insects that happen to fall into the water; and it will even feed on cray-fish. It will rise to a fly. Some of this kind have been known to weigh eight or nine pounds.

9. The alburnus, or bleak. These fish are very common in many of our rivers, and keep together in large shoals. At certain seasons they seem to be in great agonies; they tumble about near the surface of the water, and are incapable of swimming far from the place: but in about two hours they recover and disappear. Fish thus affected, the Thames fishermen call mad bleaks. They seem to be troubled with a species of gordius, or hair-worm, which torments them so, that they rise to the surface and then die. The bleak seldom exceeds five or six inches in length. Artificial pearls are made with the scales of this fish; and probably also with those of the dace. They are beaten into a fine powder, then diluted with water, and introduced into a thin glass bubble, which is afterwards filled with wax. The French were the inventors of this art. During the month of July there appear in the Thames, near Blackwall and Greenwich, innumerable multitudes of small fish, known to the Londoners by the name of white-bait. They are esteemed very delicious when fried with fine flour, and occasion, during the season, a vast resort of the lower order of epicures to the taverns at the places where they are taken. There are various suppositions concerning these fishes, all of which terminate in reckoning them the fry of some other fish. Mr. Pennant thinks they are of the carp kind; though he cannot determine the species to which they belong. They have a greater similarity to the bleak than to any other, but he thinks they cannot be the young fry of this species; because the bleak is found in many of the British streams, but the white-bait only in the Thames. The usual length of this fish is only two inches.

10. The auratus, or golden fish, a small fish, domesticated by the Chinese, and generally kept for ornament by great people in their courts and gardens. They breed them in small ponds made for the purpose, in basons, and even in porcelain vessels. This fish is no larger than our pilchard. The male is of a bright red colour, from the top of the head to the middle of the body: the rest is of a gold colour; but it is so bright and splendid, that the finest gilding, according to F. le Comte, cannot approach it. The female is white, but its tail and half of its body resemble the lustre of silver. F. du Halde, however, observes, that a red and a white colour are not always the distinguishing marks of the male and female; but that the females are known by several white spots, which are seen round the orifice that serves them as organs of hearing; and the males, by having these spots much brighter. Gold-fish are light and lively; they love to sport on the surface of the water, soon become familiarized, and may even be accustomed to come and receive their food on sounding a small rattle. Great care is necessary to preserve them; for they are extremely delicate, and sensible of the least injuries of the air; a loud noise, such as that of thunder or cannon; a strong smell, a violent shaking of the vessel, or a single touch, will often destroy them. These fish live with little nourishment; those small worms which are engendered in the water, or the earthy particles that are mixed with it, are sufficient for their food. The Chinese, however, take care from time to time, to throw into the basons and reservoirs where they are kept, small balls of paste, which they are very fond of when dissolved; they give them also lean pork, dried in the sun, and reduced to a fine and delicate powder, and sometimes snails: the slime which these insects leave at the bottom of the vessel is a great delicacy for them, and they eagerly hasten to feed on it. In winter they are removed from the court to a warm chamber, where they are kept generally shut up in a porcelain vessel. During that season they receive no nourishment; however, in spring, when they are carried back to their former bason, they sport and play with the same strength and liveliness as they did the preceding year.

In warm countries these fish multiply fast provided care is taken to collect their spawn, which floats on the water, and which they almost entirely devour. This spawn is put into a particular vessel, exposed to the sun, and preserved until vivified by the heat. Gold-fish, however, seldom multiply when they are kept in close vases, because they are then too much confined. In order to render them fruitful, they must be put into reservoirs of considerable depth in some places at least, and which are constantly supplied with fresh water. At a certain time of the year, a prodigious number of barks may be seen in the great river Yangtsekiang, which go thither to purchase the spawn of the fish. Towards the month of May, the neighbouring inhabitants shut up the river in several places with mats and hurdles, which occupy an extent of almost 9 or 10 leagues; and they leave only a space in the middle sufficient for the passage of barks. The spawn of the fish, which the Chinese can distinguish at first sight, although a stranger could perceive no traces of it in the water, is stopped by these hurdles. The water mixed with spawn is then drawn up, and after it has been put into large vessels, it is sold to merchants, who transport it afterwards to every part of the empire. This water is sold by measure, and pur-

chased by those who are desirous of stocking their ponds and reservoirs with fish.

Notwithstanding the tenderness of these fish even in their native climates, they are now naturalized in Britain, where they even breed. They were first introduced into England about the year 1691; but were not generally known till 1728, when a great number were brought over, and presented first to Sir Matthew Dekker, and by him circulated round the neighbourhood of London, whence they have been distributed to most parts of the country.

Nothing can be more amusing than a glass bowl, containing such fishes: the double refractions of the glass and water represent them, when moving, in a shifting and changeable variety of dimensions, shades, and colours; while the two mediums, assisted by the convex shape of the vessel, magnify and distort them vastly; not to mention that the introduction of another element and its inhabitants into our parlours, engages the fancy in a very agreeable manner. See Plate XL. Nat. Hist. fig. 158.

CYPRIPEDIUM, *lady's slipper*, a genus of the diandria order, in the gynandria class of plants, and in the natural method ranking under the 7th order, orchideæ. The nectarium is ventricose, inflated, and hollow. There are five species; of which only one, viz. the calceolous, is a native of Britain. It grows in rough ground in different parts of the island. The other species are natives of America. None of them are easily propagated in gardens, and therefore must be transplanted from those places where they are natives. They are curious and beautiful flowers. The English species is yellow.

CYPRUS, *knights of*, an order instituted by Guy de Lusignan, titular king of Jerusalem, to whom Richard I. of England, after conquering this island, made over his right.

CYRILLA, a genus of the class and order didynamia angiospermia. The calyx is five-leaved; the cor. funnel-form; filaments inserted in the margin of the corolla; anth. cohering; germ inferior; style bent down; stigma two-lobed; caps. half two-celled; seeds numerous. There is one species, a handsome plant of the West-Indies.

CYRTANTHUS, a genus of the class and order hexandria monogynia. The corolla is tubular, inserted in the tube. There are two species, bulbs of the Cape.

CYST, the bag or tunic including all incysted tumors, as the scirrhus, atheroma, steatoma, meliceris. See SURGERY.

CYTINUS, a genus of the dodecandria order, in the gynandria class of plants, and in the natural method ranking under the 11th order, sarmentaceæ. The calix quadrifid, superior; there is no corolla; the antheræ are 16, and sessile; the fruit an octolocular polyspermous berry. There is one species.

CYTISUS, *tree trefoil*, a genus of the decandria order, in the diadelphia class of plants, and in the natural method ranking under the 32d order, papilionaceæ. The calix is bilabiated, with the upper lip bifid; inferior tridentate; the legumen attenuated at the base. There are eight species, of which the most remarkable are: 1. The laburnum, or large deciduous cytisus; has a large upright tree-stem, branching into a full-spreading head, 20 or 30 feet high, having smooth greenish branches, from the sides of which numerous yellow flowers collected into long spikes hang loosely downward, and appear in May. 2. The sessilifolius, often called cytisus secundus clusii, has a slow shrubby stem dividing into numerous erect brownish branches, forming a bushy head five or six feet high, with small oval leaves growing by threes; and bright yellow flowers in short erect spikes at the end of the branches, in June. 3. The nigricans grows with a short shrubby stem, dividing low into many erect slender branches, forming a bushy head four or five feet high, with oblong, oval, trifoliate leaves, and yellow flowers terminating all the branches in upright spikes, appearing in July. 4. The hirsutus, or hairy evergreen Neapolitan cytisus, rises with an upright shrubby grey stem, sending out many erect greenish hairy branches, forming a fine head six or eight feet high, with small hairy trifoliated leaves, and yellow flowers from the sides of the branches in short pendulous spikes, appearing in June. 5. The austriacus, Austrian, or Tartarean evergreen cytisus, has a shrubby stem, dividing low into many greenish branches, forming a bushy head three or four feet high, having smooth whitish-green leaves, and bright yellow flowers in close umbeliate heads at the ends of the branches, having a cluster of leaves under each head. These flowers appear in May. All the sorts are hardy, and will prosper in any common soil and exposure: though, as the hirsutus is sometimes affected by severe frost, it should have a dry soil, and a somewhat sheltered situation. They may all be propagated by seeds or cuttings, and all the culture they require in the nursery is to have the ground kept clear from weeds, and dug annually between the rows. Though they are generally considered only as ornamental shrubs, yet the first species, if originally trained to a stem, and suffered to stand, will grow to a size of pretty large timber-trees. They grow naturally on the Alps, the mountains of Dauphiny, and in the Highlands of Scotland; and the timber being very hard, and taking a fine polish, is frequently used for making household furniture, and is said to equal the finest mahogany in beauty. A species of cytisus, called by Linnæus cytisus cajan, is known in the West Indies, where it is a native, by the name of the pigeon-pea, from the seeds being the common food of these birds in that part of the world. These seeds are also sometimes used as food for the human species; and as they are of a very binding quality, afford a wholesome nourishment during the wet season, when dysenteries are so frequent.

D.

D, the fourth letter of the alphabet, as a numeral denotes 500; and with a dash over it, thus $\overline{D}$, 5000. Used in abbreviation, it has various significations: thus, D. stands for doctor, as M. D. doctor of medicine; D. T. doctor of theology; D. D. signifies doctor of divinity; D. D. D. is used for dat, dicat, dedicat; and four D. D. D. D. for dignum deo donum dedit. In music D marks in thorough basses what the Italians call descanto, and intimates, that the treble ought to play alone, as T does the tenor, and B the bass. D C, in the Italian music, an abbreviation of da capo, that is, from the head, or beginning. Among Roman writers D stands for divus, decimus, devotus, diebus, and diutius.

DAB. See PLEURONECTES.

DACTYL, δακτυλος, dactylus, in ancient poetry, a metrical foot, consisting of one long and two short syllables, as αλκιμος, and cāndĭdŭs. The dactyle and spondee are the only feet or measure used in hexameter verses, the former being esteemed more sprightly, and the latter more solemn and grave. Accordingly, where great activity is signified, we find the dactyls used with much propriety, as in the following verses of Virgil.

Quadrupedante putrem sonitu quatit ungula campum;

and,

Ferte cito ferrum, date tela, scandite muros.

DACTYLIS, *cock's-foot grass*, a genus of the digynia order, in the triandria class of plants, and in the natural method ranking under the 4th order, gramina. The calix is bivalved and compressed, with one valve longer than the other, carinated, or having the rachis prominent and sharp. There are seven species. The cynosuroides, or smooth cock's-foot grass, and the glomeratus, or rough cock's-foot grass, are natives of Britain; the first grows on marshy places, and the latter is common in meadows and pasture grounds. This last is eaten by horses, sheep, goats, and cows, and all herbiverous animals eat it greedily. Horses prefer it to that of any other grass.

DACTYLONOMY, the art of counting by the fingers. The rule is this; the left thumb is 1, the forefinger 2, and so on to the right thumb, which is the tenth, or last, and is denoted by the cypher.

DACZAJIE, a silver money current in Persia, and worth five mamoudis. See MAMOUDI.

[DÆDALEA, in botany, a plant of the class cryptogamia, order fungi. (*a*)

DÆMON, a name given by the ancients to certain spirits, or genii, which appeared to men, either to do them service, or to hurt them. The Platonists distinguish between gods, dæmons, and heroes. The gods are those whom Cicero calls dii majorum gentium. The dæmons are those whom we call angels. Christians, by the word dæmon, understand only evil spirits, or devils. Justin Martyr speaks of the nature of dæmons as if he thought them not absolutely spiritual and incorporeal, for which reason he attributes such actions to them as cannot be performed without the intervention of a body.

The Mahometans allow several sorts of dæmons; and the miners of Hungary pretend that while they are at work in the mines, they often see dæmons in the shape of little negro-boys, doingth em no other harm than often extinguishing their lights.

DÆMONIACS, in church-history, a branch of the anabaptists, whose distinguishing tenet is, that the devils shall be saved at the end of this world.

DAGGYSA, a genus of the vermes class, and mollusca order, of which there is only a single species. The body is loose, noyant, angular, tubular, and open at each extremity: it is marked at one end with a brown spot. The dagysa inhabits the Spanish sea, is about three inches long, and one inch thick. They adhere to each other by the sides, and so nearly resemble the genus salpa, that it is thought they might, with propriety, be incorporated into one.

DAIS, a genus of the monogynia order, in the decandria class of plants, and in the natural method ranking under the 31st order, vepreculæ. The involucrum is tetraphyllous; the corolla quadrifid or quinquefid; the fruit a monospermous berry. There are three species, natives of India and the Cape.

DAKIR, in our statutes, is useed for the twentieth part of a last of hides. According to the statute of 51 Hen. III. de compositione ponderum and mensurarum, a last of hides consists of 20 dakirs, and every dakir of 10 hides. But by 1 Jac. cap. 33. one last of hides or skins is 12 dozen.

DALBERGIA, a genus of the decandria order, in the diadelphia class of plants. There are two filaments or stamina quadrifid at top. The fruit is pedicellated, not gaping, leguminous, membrano-compressed, and bearing seeds. There are two species, trees of Malabar and Surinam.

[DALEA, in botany, a genus of the diadelphia, decandria class and order. The calix is quinquefid, the pod one seeded; there are six species, mostly annual; the colour of the flowers varied. They are natives of Tennessee, Illinois, and Georgia. (*b.*)

DALIBARDA, in botany, a genus of the class icosandria, order polygynia. The calix is quinquefid, the corolla quinquepetalous; there are two species, persisting, natives of Pennsylvania. Flowers in May and June. (*c.*)

DALECHAMPIA, a genus of the monadelphia order, in the monœcia class of plants, and in the natural method ranking under the 38th order, tricoccæ. The involucrum of the male is common and quadripartite; the calyces hexaphyllous; corolla none; the nectarium laminated or scaly; the stamina monadelphous or coalited at the base; and polyandrous or numerous. The female involucrum is common and triphyllous; corolla none; style one; the capsule tricoccus. There are two species, of which the scandens is a native of Jamaica. It is a climbing plant, which rises to a considerable height, and is remarkable for nothing but having its leaves armed

with bristly hairs, which sting the hands of those who touch them.

DALLE, a nominal money, used in keeping books of account in many cities of Germany. It is worth 32 sols lubs, which make 40 French sols.

DAMAGE, generally signifies any hurt or hindrance that a man receives in his estate; but in the plural in common law, are the recompence that is given to a man by a jury as a satisfaction for some injury sustained; as for battery, imprisonment, slander, or trespass. 2 Black. 438.

In actions upon the case, the jury may find less damages than the plaintiff lays in his declaration, though they cannot find more; but costs may be increased beyond the sum mentioned in the declaration for damages; for costs are given in respect of the plaintiff's suit to recover his damages, which may be sometimes greater than the damage. 10 Co. 115. A jury may, and now frequently do, give interest on book-debts, in name of damages.

For a more general account of damages, see 7 Vin. Abr. and 2 Bac. Abr. title Damage.

DAMAGE-*feasant* or *faisant*, is where the beasts of another come upon a man's land, and there feed, tread, or spoil his corn or grass there growing; in which case the owner of the ground may distrain and impound them, till satisfaction be made. Wood, b. 4. c. 4.

DAMAGE *cleer*, was formerly a fee or gratuity (generally a tenth part of the damages recovered) paid to the prothonotaries or clerks of the king's-bench, common-pleas and exchequer. But this is abolished by 17 C. II. c. 6. s. 2. and if any officer shall take any money in the name of damage cleer, or in lieu thereof, or shall delay to sign any judgment until damage cleer is paid, he shall forfeit treble the sum so taken or demanded to the party grieved.

DAMASK, a silk stuff, with a raised pattern, so that the right side of the damask is that which has the flowers raised or saturated. Damasks should be of dressed silk, both in warp and woof; and in France, half an ell in breadth: they are made at Chalons in Champagne, and in some places in Flanders, as at Tournay, &c. entirely of wool, 3-8ths of an ell wide, and 20 ells long.

DAMASK is also a kind of wrought linen made in Flanders and in this country. It takes its name on account of its resemblance to damasks. It is chiefly used for table linen.

DAMASK is also applied to a very fine steel, in some parts of the Levant, chiefly at Damascus in Syria; whence its name. It is used for sword and cutlass-blades, and is finely tempered. See STEEL.

DAMASKEENING, or DAMASKING, the art or operation of beautifying iron, steel, &c. by making incisions in them, and filling them up with gold and silver wire; chiefly used for adorning sword-blades, guards, and gripes, locks of pistols, &c. Damaskeening partakes of the mosaic, of engraving, and of carving: like the mosaic, it has inlaid works; like engraving, it cuts the metal representing different figures; and as in chasing, gold and silver are wrought in relievo. There are two ways of damasking: the one, which is the finest, is when the metal is cut deep with proper instruments, and inlaid with gold and silver wire: the other is superficial only.

DAMASONIUM, a genus of the hexandria class and order. The spathe is one-leafed; perianthium one-leafed, three-parted; berry ten-celled, inferior. There is one species, a native of India.

DAMELOPRE, a kind of bilander, used in Holland for conveying merchandize from one canal to another, being very commodious for passing under the bridges.

DAMIANISTS, in church history, a branch of the ancient acephali severitæ. They agreed with the catholics in admitting the fourth council, but disowned any distinctions of persons in the Godhead; and professed one single nature, incapable of any difference; and yet they call God the Father, Son, and Holy Ghost.

DAMPS, in natural history, are certain noxious exhalations issuing from some parts of the earth, and which prove almost instantly fatal to those who breathe them. These damps are chiefly observed in mines and coal-pits; though vapours of the same kind often issue from old lavas of burning mountains; and in those countries where volcanoes are common, will frequently enter houses, and kill people suddenly without the least warning of their approach. In mines and coal-pits they are chiefly of two kinds, called by the miners and colliers the choke and fire damps (see AIR); and both go under one general name of foul air. The choke-damp is carbonic acid gas; and usually infests those places which have been formerly worked, but long neglected, and are known to the miners by the name of wastes. No place, however, can be reckoned safe from this kind of damp, except where there is a due circulation of air; and the procuring of this is the only proper means of preventing accidents from damps of all kinds. The choke-damp suffocates the miners suddenly. Being heavy, it descends towards the lowest parts of the workings, and thus is dangerous to the miners, who can scarcely avoid breathing it. The fire-damp, which seems chiefly to be composed of hydrogen gas, rises to the roof of the workings, as being specificially lighter than the common atmosphere; and hence, though it will suffocate as well as the other, it seldom proves so dangerous in this way as by its inflammable property, by which it often takes fire from the candles, and explodes with great violence.

In the Philosophical Transactions, No. 119, there is an account of some explosions by damps of this kind, on which we have the following observations: 1. Those who are in the place where the vapour is fired, suddenly find themselves surrounded with flames, but hear little or no noise; though those who are in places adjacent, or above-ground, hear a very great one. 2. Those who are surrounded by the inflamed vapour feel themselves scorched or burnt, but are not moved out of their places, though such as unhappily stand in the way of it are commonly killed by the violence of the shock, and often thrown with great force out at the mouth of the pit; nor are the heaviest machines found able to resist the impetuosity of the blast. 3. No smell is perceived before the fire, but a very strong one of brimstone is afterwards felt. 4. The vapour lies towards the roof, and is not perceived if the candles are held low; but when these are held higher, the damp descends like a black mist, and catches hold of the flame, lengthening it to two or three handfuls; and this appearance ceases when the candles are held nearer the ground. 5. The flame continues in the vault for several minutes after the explosion. 6. Its colour is

blue, something inclining to green, and very bright. 7. On the explosion of the vapour, a dark smoke like that proceeding from fired gun-powder is perceived. 8. Damps are generally observed to come about the end of May, and to continue during the heat of summer. They return several times during the summer season, but observe no certain rule.

Among the other uses to which oxygen might be applied, Mr. Cavallo reckons that of securing people from the dangerous effects of damps in mines, and other subterraneous places. "If a large bladder," says he, "into which a solution of lime in water is introduced, is filled with dephlogisticated air, (oxygen-gas), and a small wooden or glass pipe is adapted to its neck, a man may hold that pipe in his mouth, and may breathe the dephlogisticated air; and thus equipped, he may venture into these subterranean places, amidst the various elastic fluids contained in them. A large bladder of dephlogisticated air will serve for above a quarter of an hour, which is a length of time sufficient for various purposes; besides, if longer time is required to be spent in these places, a person may have two or more bladders of dephlogisticated air along with him, and may shift as soon as the air of one is contaminated. Without the necessity of any more complicated apparatus, the bladders full of dephlogisticated air may be kept stopped by putting corks into the glass or wooden pipes that are tied to their necks. This air might also be used for diving-bells."

DANAE, in antiquity, a coin somewhat more than an obolus, used to be put into the mouths of the dead, to pay their passage over the river Acheron.

DANCE, a silly amusement of the idle and thoughtless.

DANCETTE, in heraldry, is when the outline of any bordure or ordinary is indented very largely, the largeness of the indentures being the only thing that distinguishes it from indented.

DANK, a piece of silver current in Persia, and some parts of Arabia, weighing the 16th part of a drachm. It is also a weight used by the Arabians to weigh jewels and drugs.

DAPHNE, spurge-laurel, a genus of the monogynia order, in the octandria class of plants, and in the natural method ranking under the 31st order, vepreculæ. There is no calix; the corolla is quadrifid and withering, inclosing the stamina. The fruit is a monospermous berry. There are 28 species, of which the following are the most remarkable:

1. Mezereum, the mezereon or spurge-olive, is a low deciduous shrub. It is a native of Germany, and has been discovered in this country in some woods near Andover in Hampshire. Of this elegant plant there are four varieties: 1. the white; 2. the pale red: 3. the crimson; and 4. the purple-flowering. Hanbury is very lavish in praise of these shrubs. He says, "they have each every perfection to recommend them as flowering shrubs. In the first place, they are of low growth, seldom rising to more than three or four feet in height, and therefore are proper even for the smallest gardens. In the next place they will be in bloom when few trees, especially of the shrubby tribe, present their honours. It will be in February, nay sometimes in January; then will the twigs be adorned with flowers all around from one end to the other. Each twig has the appearance of a spike of flowers of the most consummate lustre; and as the leaves are not yet out, whether you behold this tree near or at a distance, it has a most enchanting appearance. But this is not all: the sense of smelling is peculiarly regaled by the flowers; their spicy sweetness is diffused around, and the air is perfumed with their odours to a considerable distance. Many flowers deemed sweet, are not liked by all; but the agreeable inoffensive sweetness of the mezereon has ever delighted the sense of smelling, whilst the lustre of its blow has feasted the eye. Neither is this the only pleasure, the tree bestows; for besides the beauty of the leaves which come out after the flowers are fallen, and which are of a pleasant green colour and an oblong figure, it will be full of red berries in June, which will continue growing till the autumn. Of these berries the birds are very fond; so that whoever is delighted with those songsters, should have a quantity of them planted all over the outsides of his wilderness quarters."

2. Cnidium, the flax-leaved daphne, is a low deciduous shrub; a native of Italy, Spain, and about Montpellier. This species seldom grows higher than three feet. The branches are very slender, and ornamented with narrow, spear-shaped, pointed leaves, much like those of the common flax. The flowers are produced in panicles at the ends of the branches; they are small, come out in June, but are rarely succeeded by seeds in England.

3. Cneorum, the spear-leaved daphne, is a very low deciduous shrub; a native of Switzerland, Hungary, the Alps, and the Pyrenean mountains. This rises with a shrubby branching stalk, to about a foot or a foot and a half high. The leaves are narrow, spear-shaped, and grow irregularly on the branches. The flowers are produced in clusters at the ends of the little twigs: they make their appearance in March, are of a purple colour, and possessed of a fragrance superior even to that of the mezereon; but they are seldom succeeded by seeds in England.

4. Tartonraira, the oval-leaved daphne or tartonraire, a very long deciduous shrub, is a native of France and Italy. This rises with a woody stalk to the height of about two feet. The branches are numerous, irregular, tough, and covered with a light-brown-coloured bark. The leaves are oval, very small, soft to the touch, and shining. The flowers are produced in clusters from the sides of the stalks: they are white, come out in June, and are succeeded by roundish berries, which seldom ripen in England.

5. Alpina, the alpine daphne or chamelæa, is a low deciduous shrub; native of the Alps, Geneva, Italy, and Austria. This will grow to the height of about a yard. The leaves are spear-shaped, obtuse, and hoary underneath. The flowers come out in clusters from the sides of the branches, and are very fragrant: they appear in March, and are succeeded by red berries, that ripen in September.

6. Thymelæa, the milkwort-leaved daphne, or the thymelæa, a low deciduous shrub, native of Spain and the south of France. The thymelæa will grow to the height of a yard. The stalks of this species are upright, branched, and covered with a light-brown bark. The leaves are spear-shaped, smooth, and in some respect resemble those of milkwort. The flowers are produced

in clusters from the sides of the stalks: they are of a greenish colour, have no footstalks, appear in March, and are succeeded by small yellowish berries, which will be ripe in August. This and the two former sorts require a dry soil, and a warm situation.

7. Villosa, the hairy-leaved daphne, a very low deciduous shrub, native of Spain and Portugal. The stalks are ligneous, about two feet high. The flowers have very narrow tubes, are small, and make no great show: they come out in June, and are not succeeded by ripe seeds in England. This shrub, in some situations, retains its leaves all winter in such beauty, as to cause it to be ranked among the low-growing evergreens; but as in others it is sometimes shattered with the first bleak winds, it is left to the gardener whether to place this shrub among the deciduous trees or evergreens.

8. Laureola, the spurge-laurel or evergreen daphne, a low evergreen shrub, common in some parts of Britain, also in Switzerland and France. This shrub seldom grows more than a yard or four feet high; and is also valuable on account of its flowers; not because they make any great show, but from their fragrance, and the time they appear; for it will be in flower the beginning of January, and will continue so until the middle or end of April before the flowers fall off.

9. The odora is a charming shrub, which has its specific name from the delightful fragance of its flowers. In appearance it much resembles the common spurge-laurel, but must be treated as a greenhouse plant.

The root of the mezereon was long used in the Lisbon diet-drink, a remedy said to be good for several complaints, particularly nodes and other symptoms resisting the use of mercury. The composition of this diet-drink is described in the Edinburgh Physical Essays, by Dr. Donald Monro of London. On chewing the root of the mezereon, it proves very pungent, and its acrimony is accumulated about the fauces, and is very durable. It is employed chiefly under the form of decoction, and it enters the decoctum sarsaparillæ compositum of the London college; but it has also been used in powder combined with some inactive one, as that of liquorice-root. It is apt to occasion vomiting and purging; so must be begun in grain-doses, and gradually increased. It is often usefully combined with mercury. The bark of the root, which is the most acrimonious part, is recommended in the Pharmacopœia Chirurgica, to be steeped in vinegar, and applied to promote the discharge of issues. Mezereon has also been of use in tumours and cutaneous eruptions not venereal. The whole plant is very corrosive; and six of the berries, it is said, will kill a wolf. A woman gave 12 grains of the berries to her daughter, who had a quartan ague: she vomited blood, and died immediately.

DARAPTI, among logicians, one of the modes of syllogisms of the third figure, whose premises are universal affirmatives, and the conclusion is a particular affirmative: thus,

DAR- Every body is divisible:
AP- Every body is a substance;
TI. Therefore some substance is divisible.

DARIC, in antiquity, a famous piece of gold, first coined by Darius the Mede about 538 years before Christ; probably during his stay at Babylon, out of the vast quantity of gold which had been accumulated in the treasury. It was dispersed over the East, and also into Greece; so that the Persian daric, which was also called stater, was the gold coin best known in Athens in ancient times. According to Dr. Bernard, it weighed two grains more than one of our guineas; but as it was very fine, and contained little alloy, it may be reckoned worth about 25*s.* of our money.

DARII, in logic, one of the modes of syllogisms of the first figure, in which the major proposition is an universal affirmative, and the minor and conclusion particular affirmatives: thus,

DA- Every thing that is moved, is moved by another:
RI- Some body is moved;
I. Therefore, some body is moved by another.

DARRIEN, in law, a corruption of the French word dernier, *last*, is used in this sense in our law, as *darrien continuance*, &c.

DARRIEN *presentment*, the last presentation to a church, on which an assize lies.

DASYPUS, *armadillo*, a genus of quadrupeds of the bruta order. The generic character is: grinders several, without either cutting or canine teeth; body coated with a shelly armour, divided into zones.

The armadillos are natives of South America, and are readily distinguished from all other quadrupeds by the singular covering with which nature has ornamented them; and which forms a complete suit of armour, divided into bands or shelly zones, in such a manner as to accommodate itself to the various postures of the body; and exhibiting a most beautiful example of deviation from the general structure and appearance in quadrupeds. The armadillos are innoxious animals, and inhabit subterraneous retreats or burrows, which they readily excavate by means of their large and strong claws. They wander about chiefly by night, and devour various roots and grain; and therefore considered as injurious to plantations. They also occasionally prey on the smaller animals of different kinds; as worms, insects, &c. In a state of captivity, they readily eat animal food, and that in considerable quantity.

They are themselves considered as excellent food, and are therefore dug out of their subterraneous cavities, and sold for the table. When old, however, their flesh acquires a strong musky scent, and becomes unfit for use. When attacked, the armadillos roll themselves up into the form of a ball, and thus become, in a great degree, invulnerable. Nothing can exceed the curious mechanism by which this is performed; nor is it possible to view without admiration the appearance of the animal thus coiled up, and secured from common contingencies.

Armadillos are said to drink frequently, and they often grow extremely fat. They are very prolific animals; and are said to breed three or four times a year, and to bring several young at a birth. The species are determined by the number of shelly zones on the body. In enumerating these, however, it is remarkable that most authors vary; and the exact discrimination of all the species seems yet a desideratum in natural history. This, perhaps, arises partly from the inattention of draughtsmen and engravers, when representing the animals, and partly from different authors counting differently the

bands on some of the species; which are so placed as to make it difficult in some instances to distinguish the ultimate or bounding zones of the body, from the scaly divisions on the fore and hind parts of the animal; and which, like the bands, are disposed into a kind of zones, though less strongly marked. Some species, however, are so clearly defined by this mode of distinction, as to be at all times readily ascertained.

1. Dasypus tricinctus, or three-banded armadillo, may be considered, perhaps, as the most elegant of the whole species; the pattern of the armour being peculiarly neat and well defined, and the colour of the animal more pleasing than in most other species, viz. a clear yellowish-white. The head, shoulders, and hind part of the body, are coated with regular hexagonal divisions, curiously studded or tuberculated on the surface; and the zones of the body are extremely distinct, and only three in number. The ears are rather large, and the claws smaller than in most other species. It is a native of Brazil.

2. Dasypus sexcinctus, or six-banded armadillo, is also a species of great elegance; and much resembles the former, but is furnished with six bands instead of three. The tail is very thick at the base, and is short in proportion to the animal; the claws are very large and strong. The bands are marked into oblong squares, as in the former.

3. Dasypus septemcinctus, or seven-banded armadillo. It is impossible to consider this in any other light than as a mere variety of the nine-banded armadillo, in which the pattern of the armour, and the relative proportions of the parts, are sufficient to ascertain the species, whatever may happen to be the number of the zones.

4. Dasypus novemcinctus, or nine-banded armadillo. The number of bands or zones in this species is generally nine: they are extremely distinct or well defined, and are transversely marked by very numerous wedge-shaped or acutely-triangular figures alternating with smaller opposite ones: and the head is smaller, longer in proportion, and sharper-snouted, than in any other species; the fore and hind parts of the shield or covering are marked by very numerous flat rounded scales, or tubercles, with smaller ones interposed; the ears are moderately large, and upright; the tail is longer than in any other species, and tapers gradually to the tip. It is marked by transverse rows of longish hexagonal divisions on each joint; on the fore feet are four toes, and five on the hind; the claws moderately large and strong.

5. Dasypus cingulis duodecim. This, according to the character generally given in authors, should have twelve zones or bands; but it is certain that this number is not very accurately observed by nature, and perhaps 13 or 14 is the more general number. The individuals also appear to vary in some other particulars. That described by Buffon and Mr. Pennant, under the title of the twelve-banded armadillo, has broad upright ears; the head is thick and broad, and is marked above into large angular divisions; the crust on the shoulders into oblong pieces inclining to a squarish form; that on the rump into hexagonal ones. The length of this animal, from the nose to the tail, is about a foot; the tail about seven inches or less.

6. Dasypus cingulis octodecim, or eighteen-banded armadillo, was first described by Grew, in the last century, under the name of the weezle-headed armadillo. This species seems most allied to the twelve-banded armadillo.

DATA, among mathematicians, a term for such things or quantities as are given or known, in order to find other things that are unknown. Euclid uses the word data for such spaces, lines, and angles, as are given in magnitude, or to which we can assign others equal.

In algebra the given quantities or data are expressed by the first letters of the alphabet, and the unknown quantities by the last letters; thus, if the problem be from the sum and product of two quantities given, to find the quantities themselves, the quantities are represented by y and z; and $y+z=a$ the sum given, and $yz=b$ the product given. See ALGEBRA.

DATE, in law, is the description of the day, month, year of our Lord, and year of the reign of the king, in which a deed or other writing was made. Anciently deeds had no dates but only of the month and year, and now, if in the date of any deed, the year of our Lord is right, though the year of the king's reign is wrong, it shall not hurt the same. A deed is good, though it has no date of the day, or if that be mistaken, or though it contains an impossible date; but then he that pleads such a deed must set forth the time when it was delivered: for every deed or writing has a date in law, and that is the day of the delivery, and where there is none, a plaintiff, it is said, may count it of any date.

In writings of importance, the date should be written in words at length. An antedate is a date prior to the real time when the instrument was signed. A post-date is that posterior to the real time when the instrument was passed.

DATE. See PHŒNIX.

DATISCA, a genus of the dodecandria order, in the diœcia class of plants, and in the natural method ranking under the 54th order, miscellaneæ. The male calyx is pentaphyllous; there is no corolla; the antheræ are sessile, long, and 15 in number. The female calyx is bidented; no corolla; the styles three; the capsule triangular, three-horned, unilocular, previous, polyspermous, inferior. There are two species.

DATISI, in logic, a mode of syllogism in the third figure, in which the major is an universal affirmative, and the minor and conclusion particular affirmative propositions. For example,

DA- All who serve God are kings:
TI- Some who serve God are poor;
SI. Therefore some who are poor are kings.

DATIVE, among grammarians, the third case in the declension of nouns, expressing the relation of a thing to whose profit or loss some other thing is referred. It is called dative, because usually governed by a verb, implying something to be given to some person. In English the dative is expressed by the signs *to* or *for*.

DATURA, the thorn-apple, a genus of the monogynia order, in the pentandria class of plants, and in the natural method ranking under the 28th order, luridæ. The corolla is funnel-shaped and plaited; the calyx tubular, angulated, and deciduous: the capsule quadrivalved. There are eight species: the most remarkable are,

1. The stramonium, or common thorn-apple, rises

about a yard high, with an erect, strong, round, hollow, green stalk, branching luxuriantly, having the branches widely extended on every side; large, oval, irregularly angulated, smooth, dark-green leaves; and from the divisions of the branches, large white flowers singly, succeeded by large, oval, prickly capsules, growing erect, commonly called thorn-apples. At night the upper leaves rise up and inclose the flowers. The blossoms have sometimes a tinge of purple or violet. The flowers consist of one large funnel-shaped petal, having a long tube, and spreading pentagonal limb, succeeded by large roundish capsules of the size of middling apples, closely beset with sharp spines. An ointment prepared from the leaves gives ease in external inflammations and in the hæmorrhoids. The seeds were recommended by Dr. Storck to be taken internally in cases of madness; but they seem to be a very unsafe remedy. Taken even in a small dose, they bring on a delirium, and in a large one would certainly prove fatal. Cows, horses, sheep, and goats, refuse this plant.

2. Datura arborea, is a stove-plant, much esteemed for the beauty and fragrance of its large white flowers.

DAUCUS, the carrot, a genus of the digynia order in the pentandria class of plants, and in the natural method ranking under the 45th order, umbellatæ. The corolla is a little radiated, all hermaphrodite; the fruit bristly with short hairs. There are seven species, but the only one which merits attention is the carota or common carrot. This is so well known as to need no description. There are several varieties, as the white, the orange, and the purple carrot; but of these the orange carrot is the most esteemed. It grows longer, larger, and is commonly more handsome, than the others, being often 15 or 18 inches long in the eatable part, and from two to four in diameter at top. Carrots are propagated by seeds; which are sown at different seasons of the year, in order to procure a supply of young roots for the table at all times. The season for sowing for the earliest crop is soon after Christmas; the manner of cultivating them is too well known to need any particular description.

Carrots have been greatly recommended as proper for fattening hogs; but from some experiments mentioned in the Georgical Essays it appears, that though the bacon thus fed is of excellent quality, the feeding is considerably dearer than when fed with peas, pollard, &c. In the same essays, an experiment is mentioned by Dr. Hunter, concerning the propriety of raising carrots for the use of the distiller. From a gross calculation he is induced to think that a good acre of carrots so manufactured will leave a profit of 40*l.* after deducting the landlord's rent, cultivation, distillation, and other incidental expenses. In this calculation he presumes that the spirit is worth 6*s.* per gallon, and not excised. An acre of barley will by no means produce so much spirit. A rich sandy loam is the best land for carrots; which, after the crop is removed, will be in high cultivation for corn. Attempts have also been made to prepare sugar from carrots. A poultice of carrots mitigates the pain and abates the stench of foul and cancerous ulcers. Crickets are very fond of carrots; and are easily destroyed by making a paste of powdered arsenic, wheat-flower, and scraped carrots, which must be placed near their habitations. The seeds have been reckoned diuretic; and were formerly much used as a remedy for the stone, but are at present little regarded. Carrots were first introduced into England by the Flemings in the reign of queen Elizabeth.

DAVIDISTS, in church history, a sect of Christian heretics in the 16th century; so called from David George, their leader, who began by giving out that he was the Messiah, and was sent into the world in order to people the kingdom of heaven, which was quite empty of inhabitants for want of virtuous and good men: he rejected marriage and denied the resurrection.

DAVIT, in a ship, a long beam of timber, represented by *a*, *a*, Plate XLIII. Miscel. fig. 31, and used as a crane to hoist the flukes of the anchor to the top of the bow, without injuring the sides of the ship as it ascends; an operation which by mariners is called fishing the anchor. The anchors being situated on both the bows, the davit may be occasionally shifted, so as to project over either side of the ship, according to the position of that anchor on which it is employed. The inner end of the davit is secured by being thrust into a square ring of iron *b*, which is bolted to the deck, and forelocked under the beams. This ring, which is called the span-shackle, exhibited by the figure, is fixed exactly in the middle of the deck, and close behind the foremast. Upon the outer end of the davit is hung a large block *c*, through which a strong rope traverses, called the fish-pendant, *d*; to whose foremost end is fitted a large iron hook *e*, and to its after-end a tackle or complication of pulleys *f*; the former of which is called the fish-hook, and the latter the fish-tackle. The davit, therefore, according to the sea-phrase, is employed to fish the anchor; which being previously catted, the fish-hook is fastened upon its flukes; and the efforts of the tackle being transmitted to the hook by means of the fish-pendant, it draws up that part of the anchor sufficiently high upon the bow to fasten it, which is done by the shank-painter. There is also a davit of a smaller kind occasionally fixed in the long-boat, and employed to weigh the anchor.

DAY, according to the most natural and obvious sense of the word, signifies that space of time during which it continues to be light; in contradistinction to night, being that partition of time wherein it is dark; but the space of time in which it is light, being somewhat vague and indeterminate, the time between the rising and setting of the sun is usually looked on as the day, and the time which lapses from its setting to its rising again the night.

The word day is often taken in a larger sense, so as to include the night also; or to denote the time of a whole apparent revolution of the sun round the earth, in which sense it is called by some a natural day, and by others an artificial one: but to avoid confusion it is usual to call it in the former sense simply the day, and in the latter a nychthemeron, by which term that acceptation of it is aptly denoted, as it implies both day and night.

The nychthemeron is divided into 24 parts, called hours: which are of two sorts; equal, and unequal or temporary.

Different nations begin their day at a different hour; thus the Egyptians began their day at midnight, from whom Hipparchus introduced that way of reckoning into

astronomy; and Copernicus and others have followed him: but the greater part of astronomers reckon the day begun at noon, and so count 24 hours, till the noon of the next day; and not twice twelve, according to the vulgar computation. The method of beginning the day at midnight prevails also in America, Great Britain, France, Spain, and most parts of Europe. The Babylonians began their day at sun-rising; reckoning the hour immediately before its rising again the 24th hour of the day, whence the hours reckoned this way are called the Babylonic. In several parts of Germany, they begin their day at sun-setting, and reckon on till it sets next day, calling that the 24th hour: these are generally termed Italian hours. The Jews also began their nychthemeron at sun-setting; but then they divided it into twice twelve hours, as we do; reckoning twelve for the day, be it long or short, and twelve for the night; so that their hours continually varying with the day and night, the hours of the day were longer than that of the night for one half-year, and the contrary the other; whence their hours are called temporary: those at the time of the equinoxes became equal, because then those of the day and night are so. The Romans also reckoned their hours after this manner, as do the Turks at this day. This kind of hours are called planetary, because the seven planets were anciently looked upon as presiding over the affairs of the world, and taking it by turns each of these hours, according to the following order: Saturn first, then Jupiter, Mars, the Sun, Venus, Mercury, and last of all the Moon; hence they denominated each day of the week from that planet whose turn it was to preside the first hour of the nychthemeron. Thus assigning the first hour of Saturday to Saturn, the second will fall to Jupiter, the third to Mars, and so the 22d of the same nychthemeron will fall to Saturn again; and therefore the 23d to Jupiter, and the last to Mars: so that on the first hour of the next day it will fall to the Sun to preside; and by the like manner of reckoning, the first hour of the next will fall to the Moon; of the next, to Mars; of the next, to Mercury; of the next, to Jupiter; of the next, to Venus: hence the days of the week came to be distinguished by the Latin names of *dies Saturni, Solis, Lunæ, Martis, Mercurii, Jovis*, and *Veneris;* and among us, by the names of Saturday, Sunday, Monday, &c.

DAY, in a legal sense, relates to the day of appearance of parties, or the continuance of suits, where a day is given. In real actions there are common days, and special days given by the judges in an assize, &c.

DAYS *in bank*, are days set down by statute or order of the court, when writs shall be returned, or when the party shall appear on the writ served. They say also, if a person is dismissed without day, he is finally discharged.

DAYS *of grace*, are those granted by the court at the prayer of the defendant or plaintiff, in whose delay it is.

DAYS *of grace*, in commerce, are a customary number of days allowed for the payment of a bill of exchange, &c. after the same becomes due. Three days of grace are allowed in the United States and in England; ten in France and Dantzic; eight at Naples; six at Venice, Amsterdam, Rotterdam, and Antwerp; four at Frankfort; five at Leipsic; twelve at Hamburgh; six in Portugal; fourteen in Spain; thirty in Genoa, &c.

DAY-LIGHT, in our law, the time after sun-rising and before sun-setting, being accounted part of the day, when the hundred is liable for any robberies committed within that time.

DEACON, διακονος, one of the three sacred orders of the christian church. In its restrained sense, it is taken for the third order of the clergy.

In the Romish church it is the deacon's office to incense the officiating priest or prelate; to lay the corporal on the altar; to receive the patern or cup from the sub-deacon, and present them to the person officiating; to incense the choir; to receive the pax from the officiating prelate, and carry it to the sub-deacon; and at the pontifical mass, when the bishop gives the blessing, to put the mitre on his head, and to take off the archbishop's pall, and lay it on the altar. In England, the form of ordaining deacons declares that it is their office to assist the priest in the distribution of the holy communion; in which, agreeably to the practice of the ancient church, they are confined to the administering of the wine to the communicants. A deacon with us is not capable of any ecclesiastical promotion; yet he may be a chaplain to a family, curate to a beneficed clergyman, or lecturer to a parish-church. He may be ordained at 23 years of age, *anno currente;* but it is expressly provided, that the bishop shall not ordain the same person a priest and deacon in the same day.

DEACONESS, a female deacon, an order of women who had their distinct offices and services in the primitive church.

DEACONRY, *diaconia*, is also the name of the chapels and oratories in Rome, under the direction of the several cardinal deacons in their respective quarters. Anciently they were seven in number; as the deaconry of St. Maria in the broad-way, the deaconry of St. Eustachio near the Pantheon, &c. answering to the seven regions of the city. They had hospitals annexed to them for the distribution of alms, and an administrator for temporal concerns, called the father of the deaconry, who was sometimes a priest and sometimes a layman. At present, there are 14 of these deaconries, or hospitals, under the direction of as many cardinals.

DEAD-MEN'S-EYES, in the sea-language, a kind of blocks with many holes in them, but no sheevers, by which the shrowds are fastened to the chains: the crow-feet reeve also through these holes; and, in some ships, the main-stays are set tawt in them; but then they have only one hole, through which the lanyards are passed several times. See Plate XLIII. Miscel. fig. 32.

DEAD-RECKONING, in navigation, the calculation made of a ship's place by means of the compass and log; the first serving to point out the course she sails on, and the other the distance run. From these two things given, the skilful mariner, making proper allowances for the variation of the compass, lee-way, currents, &c. is enabled, without any observations of the sun or stars, to ascertain the ship's place tolerably well.

DEAD-RISING, among sailors, that part of a ship which lies aft, between the keel and the floor-timbers, next adjoining to the stern-post, under the bread-room, in a ship of war.

DEAD-ROPES, on board a ship, such ropes as do not run in any block.

DEAD-WATER, at sea, the eddy-water just astern of a ship, so called because it does not pass away so swift as the water running by her sides does. They say that a ship makes much dead water when she has a great eddy following her stern.

DEADLY FEUD, in law, a profession of an irreconcilable hatred, till a person is revenged even by the death of his adversary. This enmity was allowed in the old Saxon laws; for where any person was killed, if a pecuniary satisfaction was not made to the kindred of the slain, it was lawful for them to revenge themselves by arms on the murderer.

DEADS, among miners, denotes the earth or other fossil substances which inclose the ore on every side. Hence, breaking up the deads is the removing these substances for the conveniency of carrying on their work.

DEAF, DUMB, and BLIND: a man born deaf, dumb, and blind, is considered by the law as an idiot; he being supposed incapable of understanding, as not having those senses which furnish the mind with ideas. Black. 308.

DEAFFORESTED, a term found in law-books, signifying that a place is discharged from being a forest, or freed from the forest-laws.

DEAFNESS, the state of a person who either wants the sense of hearing or has it greatly impaired.

The causes of deafness are a cutting off the external ear, or an obstruction of the auditory passage, from wax or other things; a rupture of the membrane of the tympanum; or when it is corroded, or ulcerated, or the auditory nerve is obstructed or compressed. External causes are, great falls; excessive noise, such as the explosion of cannon; likewise acute diseases or inflammations, which are likely to terminate by a critical hæmorrhage.

Those born deaf are also dumb, as not being able to learn any language, at least in the common way. As the eyes, however, in some measure serve them for ears, they may understand what is said by the motion of the lips, tongue, &c. of the speaker; and even accustom themselves to move their own as they see other people do, and by this means learn to speak. This fact was observed by bishop Burnet with respect to a young lady, the daughter of a Mr. Goddy, minister of St. Gervais' church in Geneva. At two years of age it was observed that she had lost her hearing; and was ever afterwards, though she had some perception of great noises, incapable of hearing an articulate sound. Being, however, of quick parts, she carefully observed the motions of the lips of those who spoke to her; and by an imitation of these she enabled herself to articulate a number of words so as to hold a conversation with those who were in habits of familiarity with her. She however was incapable of this in the dark, as she could not distinguish the motions of their lips. But the most extraordinary of all is, that she had a sister with whom she was accustomed to sleep; and by laying her hand on her sister's mouth, she was able to perceive what was spoken even in the dark.

Like the blind, this unfortunate class of persons were long neglected; they were considered as idiots, and confirmed as such by this cruel inattention. The author of this article, however, knew a most beautiful and accomplished young lady in the north of England, who, by the force of an extraordinary genius, though labouring under this misfortune, taught herself to read and write, and various other branches of science, with no regular instruction. She wrote a fine hand, and her composition in her letters was easy and rather elegant though not perfect or quite free from errors. She was an excellent arithmetician, and at the age of twenty actually kept her father's books, who was a man in a considerable line of business. Dr. Wallis is said to have taught two young gentlemen who were deaf and dumb to understand what was said to them, and to return pertinent answers. A Swiss physician, at Amsterdam, of the name of Ammen, was equally successful with several children; and reduced the art to a system, which was published at Amsterdam in 1692, under the title of Surdus Loquens. It was probably upon these hints that the celebrated Abbe' de l'Epe'e instituted his school for the deaf and dumb. The plan has also been most successfully pursued in England by the late Mr. Braidwood, Mr. Telfair, and others; and a public charity has even been established in Southwark, for the benevolent purpose of instructing such of the children of the poor, as through this misfortune would otherwise have been lost to society.

It is observed, that deaf persons, or rather those who are hard of hearing, hear better and more easily if a loud noise be raised at the time when we speak to them: which is owing, no doubt, to the greater tension of the ear-drum on that occasion. Dr. Wallis mentions a deaf woman, who if a drum was beaten in the room could hear any thing very clearly; so that her husband hired a dummer for a servant, that by this means he might hold conversation with his wife. But with regard to this opinion there may be much deception; the sense of feeling being so nearly allied to that of hearing as to convey certain vibrations which afford information to the mind, although the party be completely deaf. See MEDICINE, and DUMBNESS.

DEAL, a thin kind of fir-planks, of great use in carpentry: they are formed by sawing the trunk of a tree into a great many longitudinal divisions, of more or less thickness, according to the purposes they are intended to serve. Deals are rendered much harder, by throwing them into salt-water as soon as they are sawed, keeping them there three or four days, and afterwards drying them in the air or sun; but neither this nor any other method yet known will preserve them from shrinking.

DEAN, an ecclesiastical officer, or dignitary: he is next under the bishop, and chief of the chapter, ordinarily in a cathedral church. There are four sorts of deans and deanries. The first is a dean who has a chapter consisting of prebendaries or canons, subordinate to the bishop, as a council assistant to him in matters spiritual, relating to religion, and in matters temporal, relating to the temporalities of his bishopric. The second is a dean who has no chapter, and yet is presentative and has cure of souls: he has a peculiar, and a court wherein he holds ecclesiastical jurisdiction, but is not subject to the visitation of the bishop or ordinary; such is the dean of Battle in Sussex. The third

dean is also ecclesiastical, but the deanry is not presentative, but donative; nor has he any cure of souls, but is only by covenant or condition; and he has also a court and peculiar, in which he holds plea and jurisdiction, of all such matters and things as are ecclesiastical, and which arise within his peculiar, which often extends over many parishes; such deans constituted by commission from the metropolitan of the province, are the dean of the Arches, and the dean of Bocking in Essex. The fourth sort of dean, is he who is usually called the rural dean; having no absolute judicial power in himself, but being to order the ecclesiastical affairs within his deanry and precinct, by the direction of the bishop or of the archdeacon; he is a substitute of the bishop in many cases.

DEATH of persons. There are a natural death of a man, and a civil death; natural where nature itself expires and extinguishes, and civil where a man is not actually dead but is adjudged so by law. If any person, for whose life any estate has been granted, remain beyond sea, or is otherwise absent, seven years, and no proof is made of his being alive, such person shall be accounted naturally dead; though if the party be afterwards proved living at the time of eviction of any person, then the tenant, &c. may reenter; and recover the profits. Stat. 19 C. II. c. 6. And persons in reversion or remainder after the death of another, upon affidavit that they have cause to believe such other dead, may move the lord chancellor to order the person to be produced; and if he be not produced, he shall be taken as dead, and those claiming may enter, &c. 6 Anne, c. 18.

Death's Part, or dead-man's part, is that portion of his personal estate, which remained after his wife and children had received thereout their respective reasonable parts; which was, if he had both a wife and a child or children, one-third part; if a wife and no child, or a child or children and no wife, one-half; if neither wife nor child, he had the whole to dispose of by his last will and testament: and if he made no will, the same was to go to his administrators. And within the city of London, and throughout the province of York, at this day, in case of intestacy, the wife and children are entitled to their said reasonable part, and the residue only is disputable, by the statute of distribution.

Death-watch, in natural history, a little insect famous for a ticking noise, like the beat of a watch, which superstitious people take for a presage of death in the family where it is heard: whence it is also called pediculus fatidicus, mortisaga, pulsitorius, &c. There are two kinds of death-watches. Of the first we have a good account in the Phil. Trans. by Mr. Allen. It is a small beetle, 5-16ths of an inch long, of a darkbrown colour, spotted; having pellucid wings under the vagina, a large cap or helmet on the head, and two antennæ proceeding from beneath the eyes, and doing the office of proboscides. The part it beats with, he observed, was the extreme edge of the face, which he chooses to call the upper-lip; the mouth being protracted by this bony part, and lying underneath out of view. This account is confirmed by Dr. Derham; with this difference, that instead of ticking with the upper lip, he observed the insect to draw back its mouth, and beat with its forehead. That author had two death-watches, a male and a female, which he kept alive in a box several months; and could bring one of them to beat whenever he pleased, by imitating its beating. By this ticking noise, he could frequently invite the male to coition with the other. When the male found he got up in vain, he would get off again, beat very eagerly, and then up again; whence the ingenious author concludes those pulsations to be the way whereby these insects woo one another, and find out and invite each other to copulation.

The second kind of death-watch is an insect in appearance quite different from the first. The former only beats seven or eight strokes at a time, and quicker: the latter will beat some hours together without intermission; and his strokes are more leisurely, and like the beat of a watch. This latter is a small greyish insect, much like a louse when viewed with the naked eye.

It is very common in all parts of the house in the summer months. It is very nimble in running to shelter, and shy of beating when disturbed; but will beat very freely before you, and also answer the beating, if you can view it without giving it disturbance, or shaking the place where it lies, &c. The author cannot say whether they beat in any other thing, but he never heard their noise except in or near paper. As to their noise, the same person is in doubt whether it is made with their heads, or rather snouts, against the paper; or whether it is not made after some such manner as grasshoppers and crickets make their noise. He inclines to the former opinion. The reason of his doubt is, that he observed the animal's body to shake and give a jerk at every beat, but he could scarcely perceive any part of its body to touch the paper. But its body is so small and near the paper, and its motion in ticking so quick, that he thinks it might be, yet he did not perceive it. The ticking, as in the other, he judges to be a wooing act; as having observed another, after much beating, come and make offers to the beating insect; who, after some offers, left off beating, and got upon the back of the other. When they were joined he left off again; and they continued some hours joined tail to tail, like dog and bitch in coition. Whether or not this insect changes its shape, and becomes another animal, he cannot say; though he has some cause to suspect that it becomes a sort of fly. It is at first a minute white egg, much smaller than the nits of lice; though the insect is nearly as big as a louse. In March it is hatched, and creeps about with its shell on. When it first leaves its shell, it is even smaller than its egg; though that is scarce discernible without a microscope. In this state it is perfectly like the mites in cheese. From the mite-state they grow gradually to their mature perfect state. When they become like the old ones, they are at first very small, but run about much more swiftly than before.

DE BENE ESSE, in law signification is to accept or allow a thing as well done for the present: thus judges frequently take bail, and declarations are frequently delivered, de bene esse, or conditionally, until special or common bail be filed.

DEBENTURE, is a certificate delivered at the custom-house, when the exporter of any goods or merchandize has complied with the regulations prescribed by cer-

tain acts of parliament, in consequence of which he is entitled to a bounty or drawback on the exportation. Stealing debentures was made felony by 2 Geo. II. chap. 25. s. 3.

DEBET DE DETINET, are Latin words used in the bringing of writs and actions. And an action shall always be in the debet et detinet, when he who makes a bargain or contract, or lends money to another, or he to whom a bond is made, brings the action against him who is the bounden party to the contract or bargain.

DEBET ET SOLET. If a man sues to recover any right by writ, whereof his ancester was disseised by the tenant of his ancestor, then he uses only the word debt in his writ; because solet is improper, as his ancestor was disseised, and the custom discontinued: but if he sues for any thing that is now first of all denied, then he uses both these words debet et solet; because his ancestor before him, and he himself usually, enjoyed the thing sued for.

DEBT, a sum due from one person to another, in consequence of work done, goods delivered, or money or other value, for which reimbursement has not been made. The non-payment in these cases is an injury, for which the proper remedy is by action of debt, to compel the performance of the contract, and recover the special sum due. 4 Co. 90.

Actions of debt are now seldom brought but upon special contracts under seal, wherein the sum due is clearly and precisely expressed: for in case of such an action upon simple contract, the plaintiff labours under two difficulties: first, the defendant has here the same advantage as in an action of detinue, that of waging his law, namely, purging himself of the debt by oath, if he thinks proper; secondly, in an action of debt, the plaintiff must recover the whole debt he claims, or nothing at all. For the debt is one single cause of action, fixed and determined: but in an action upon the case, or what is called an indebitatus assumpsit, which is not brought to compel a specific performance of the contract, but to recover damages for its non-performance, these damages are in their nature indeterminate, and will therefore adapt and proportion themselves to the truth of the case which shall be proved, without being confined to the precise demand stated in the declaration. 3 Black. 154.

DEBT, national. See NATIONAL DEBT.

DEBTOR. The gaoler shall not put, keep, or lodge, prisoners for debt, and felons, together in one room or chamber, on pain of forfeiting his office, and treble damages to the party grieved. 22 and 23 C. II. c. 20. But every gaoler ought to keep such prisoner in safe and close custody; safe, that he cannot escape; and close, without conference with others, or intelligence of things abroad. Dalt. c. 170.

DECACHORDON, in antiquity, a musical instrument with ten strings, called by the Hebrews hasur; being almost the same as our harp, of a triangular figure, with a hollow belly, and sounding from the lower part.

DECAGON, in geometry, a plane figure with ten sides and ten angles: it is called a regular decagon, when all the sides and angles are equal.

If we suppose the radius of a circle to be r, then will $\sqrt{\frac{5}{4}r^2} - \frac{1}{2}r$, or $\frac{\sqrt{5}-1}{2} \times r$, be the side of a decagon inscribed in that circle. Again, supposing the side of a decagon to be 1, the area will be 8.69; whence as 1 to 8.69, so is the square of a side of any given decagon to the area of that decagon.

DECALITRON, in antiquity, a coin equivalent to $10\frac{2}{3}$ Attic oboli.

DECANDRIA, in the Linnæan system of botany, a class of plants, the great characteristic of which is, that they have hermaphrodite flowers, with ten stamina in each.

DECAPROTI, decemprimi, in Roman antiquity, officers for gathering the tributes and taxes. The decaproti were also obliged to pay for the dead; or to answer to the emperor for the quota parts of such as died, out of their own estates.

DECEIT is an offence both by common law and by statute. All practices of defrauding, or endeavouring to defraud, another of his right, are punishable by fine and imprisonment, and sometimes pillory, &c. and there is a writ called deceptione, that lies for one who receives injury or damage, &c. A writ of deceit lies against attorneys for losses sustained by their default; also against bakers, brewers, and artificers, for not selling good commodities, or refusing to perform a bargain: in all which cases, they are, by statute, liable to penalties in proportion to their offence.

DECEMPEDA, in antiquity, a rule or rod divided into ten feet, each of which was subdivided into inches, and those into digits; used in measuring of land, and by architects in giving the proper dimensions and proportions to the parts of their buildings.

DECEMVIRI, in Roman antiquity, ten magistrates chosen annually at Rome, to govern the commonwealth instead of consuls, with an absolute power to draw up and make laws for the people. One of the decemviri had all the ensigns and honours of the function, and the rest had the like in their turn, during the year of their decemvirate. In them was vested all the legislative authority ever enjoyed by the kings, or after them by the consuls. The decemviri drew up the laws of the twelve tables, thence called leges decemvirales, which were the whole of the Roman law for a considerable time.

DECENNARY, was originally a district of ten men with their families, the inhabitants whereof living together, were sureties or pledges for each others' good behaviour. See CONSTABLE.

DECEPTIONE, a writ that lies properly against him who deceitfully does any thing in the name of another, for one that receives damage or hurt thereby.

DECIDUOUS, an appellation chiefly used in respect to plants: thus, the calyx or cup of a flower is said to be deciduous, when it falls along with the flower-petals; and, on the contrary, it is called permanent, when it remains after they are fallen. Again, deciduous leaves are those which fall in autumn; in contradistinction to those of the evergreens, which remain all the winter.

DECIES TANTUM, a writ which lies against a juror who has taken money for giving his verdict; called so of the effect, because it is to recover ten times as much as he took. Stat. 98 Edw. III. c. 12 and 13. Decies tantum lies against sheriffs taking a reward for arraying a pannel. 11 H. VI. c. 14. See Vin. Abr. 378 and 382.

DECIMAL ARITHMETIC, the art of computing by decimal fractions. See ARITHMETIC.

DECK of a ship, is a planked floor from stem to stern, upon which the guns lie, and where the men walk to and fro. Great ships have three decks, first, second, and third, beginning to count from the lowermost. Half-deck reaches from the main-mast to the stem of the ship. Quarter-deck is that aloft the steerage, reaching to the round house. Flush-deck is that which lies even in a right line fore and aft, from stem to stern. A rope-deck is made of cordages, interwoven and stretched over a vessel, through which it is easy to annoy an enemy who comes to board her. They are little used but by small vessels, to defend them from privateers. See SHIPBUILDING.

DECLARATION, an exposure in writing, of the grief and complaint of the demandant, or plaintiff, against the defendant or tenant, wherein he is supposed to have done some wrong. And this ought to be plain and certain, because it both impeaches the defendant, and also compels him to answer to it. Such a declaration in an action real, is termed a count: and it is essential that the count or declaration ought to contain demonstration, declaration, and conclusion; and in the conclusion the plaintiff ought to aver, and offer to prove, his suit, and show the damages he has sustained by the wrong done him. Declaration must be certain, containing: 1. Such sufficient certainty whereby the court may give a peremptory and final judgment upon the matter in controversy. 2. That the defendant may make a direct answer to the matter contained therein. 3. That the jury, after issue joined, may give a complete verdict thereupon. 4. No blank or space to be left therein. Brown's Annal. 3. By the general rules of law, a plaintiff must declare against a defendant within twelve months after the return of the writ; but by the rules of court, if he does not deliver his declaration within two terms, the defendant may sign judgment of non pros.; though unless he takes such advantage of the plaintiff's neglect, the plaintiff may still deliver a declaration within a year.

DECLARATION is also used in Great Britain for a confession which the quakers are obliged to make and subscribe, instead of the oaths of supremacy.

DECLARATION of war, a public proclamation made by the herald at arms to the members or subjects of a state, declaring them to be at war with any foreign power, and forbidding all and every one to aid or assist the common enemy at their peril.

DECLENSION, in grammar, an inflection of nouns according to their cases, as nominative, genitive, dative, &c. It is a different thing in the modern languages, which have not properly any cases, from what it is in the ancient Greek and Latin. With respect to languages where the nouns admit of changes either in the beginning, the middle, or ending, declension is properly the expression of all those changes in a certain order, and by certain degrees called cases. With regard to languages where the nouns do not admit of changes in the same number, declension is the expression of the different states a noun is in, and the different relations it has; which difference of relations is marked by particles, as of, to, from, by, &c.

DECLINATION, in astronomy, the distance of any celestial object from the equinoctial, either northward or southward. It is either true or apparent, according as the real or apparent place of the object is considered. See GLOBES, use of.

DECLINATION of the sea-compass, or needle, is its variation from the true meridian.

DECLINATOR, or DECLINATORY, an instrument contrived for taking the declinations, inclinations, and reclinations, of planes. It is constructed in the following manner: On a square wooden board, ABCD (Plate XLIII. Mis. fig. 33) describe a semicircle AED; and divide the two quadrants AE and ED into 90° each, beginning from E, as in the figure: then having fixed a pin in the centre F, fit a ruler HI upon the same, moveable thereon, with a box and needle K (fig. 34). In order to take the declination of a plane, apply the side AD to the plane proposed, as MN (fig. 35.); and move the ruler FG, with the compass G, about the centre F, till the needle rest upon the line of the magnetical meridian of the place: if the ruler cut the quadrant in E, the plane is either directly northern or southern: but if it cut between D and E, the plane declines to the west, and if between A and E, to the east, by the quantity of the angle GFE.

Would you take the inclinations and reclinations of planes with this instrument, instead of the ruler and needle, a thread with a plummet is fitted on a pin in the centre F; then the side B C of the declinator A B C D (fig. 36.) being applied to the proposed plane, as I L, if the plum line F G cut the semicircle A E D in the point E, the plane is horizontal; or if it cut the quadrant E D, in any point at G, then will E F G be the angle of inclination: lastly, if applying the side A B to the plane, the plummet cut E, the plane is vertical. Hence if the quantity of the angle of inclination be compared with the elevation of the pole and equator, it is easily known whether the plane be inclined or reclined. See INCLINATION and RECLINATION.

DECOCTION, in pharmacy, the boiling simples or other drugs, in order to extract their virtues for some medicinal purpose. See PHARMACY.

DECOMPOSITION, in chemistry. Caloric not only increases the bulk of bodies, and changes their state from solids to liquids, and from liquids to elastic fluids, but its action decomposes a number of bodies. Thus when ammonia is heated to redness, it is resolved into azotic and hydrogen gases. Alcohol, by the same heat, is converted into carbureted hydrogen and water.

1. This decomposition is in many cases owing to the difference between the volatility of the ingredients of a compound. Thus when weak spirits, or a combination of alcohol and water, are heated, the alcohol separates, because it is more volatile than the water.

2. In general, the compounds which are but little or not at all affected by heat, are those bodies which have been formed by combustion. Thus water is not decomposed by any heat which can be applied to it; neither are sulphuric, phosphoric, or carbonic acids.

3. Almost all the combinations into which oxygen enters without having occasioned combustion, are decomposable by heat. This is the case with nitric acid, hyperoxymuriatic acid, and many of the metallic oxides.

4. All bodies that contain combustibles as componen

parts are decomposed by heat. Perhaps the metallic alloys are exceptions to this rule; at least it is not in our power to apply a temperature high enough to produce their decomposition, except in a few cases.

5. When two combustible ingredients and likewise oxygen occur together in bodies, they are always very easily decomposed by heat. This is the case with the greater number of animal and vegetable substances. But it is unnecessary to enlarge any farther on this subject, as no satisfactory theory can be given.

DECOUPLE', in heraldry, the same as uncoupled: thus a chevron decouple, is a chevron wanting so much of it towards the point, that the two ends stand at a distance from one another, being parted and uncoupled.

DECREE, in civil law, is a determination that the emperor pronounces upon hearing a particular cause between plaintiff and defendant.

Decrees of councils, are the laws made by them, to regulate the doctrine and policy of the church.

Decree is a sentence pronounced by the lord chancellor in the court of chancery, and it is equally binding upon the parties as a judgment in a court of law.

By the laws of England, a decree (notwithstanding any contempts thereof) shall not bind the goods or moveables, but only charge the persons. Chan. Rep. 193.

If a decree is obtained and inrolled, so that the cause cannot be reheard, then there is no remedy but by bill of review; which must be on error appearing on the face of the decree, or on matters subsequent thereto, as a release or a receipt discovered since. 3 M'm's. Rep. 371.

DECOY, in naval affairs, a stratagem employed by a ship of war to betray a vessel of inferior force into an incautious pursuit, till she has drawn her within the range of her cannon, or what is called within gunshot. It is usually performed by painting the stern and sides in such a manner as to disguise the ship, and represent her either much smaller and of inferior force, or as a friend to the hostile vessel, which she endeavours to ensnare, by assuming the emblems and ornaments of the nation to which the stranger is supposed to belong. When she has provoked the adversary to chase, in hopes of acquiring a prize, she continues the decoy, by spreading a great sail, as endeavouring to escape; at the same time that her course is considerably retarded by an artful alteration of her trim till the enemy approaches. Decoying is also performed to elude the chase of a ship of a superior force in a dark night, by throwing out a lighted cask of pitch into the sea, which will burn for a considerable time and misguide the enemy. Immediately after the cask is thrown out, the ship changes her course, and may easily escape, if at any tolerable distance from the foe.

Decoy, in military affairs, a stratagem to carry off the enemy's horses in a foraging party, or from the pasture; to execute which, you must be disguised, and mix on horseback in the pasture, or amongst the foragers on that side on which you propose to fly: you must then begin by firing a few shots, which are to be answered by such of your party as are appointed to drive up the rear, and are posted at the opposite extremity of the pasture or foraging-ground; after which they are to gallop from their different stations towards the side fixed for the flight, shouting and firing all the way: the horses, being thus alarmed and provoked by the example of others, will break loose from their pickets, throw down their riders and the trusses, and setting up a gallop, will naturally direct their course to the same side; insomuch, that if the number of them was ever so great, you might lead them in that manner for several leagues together; when you are got into some road, bordered by a hedge or ditch, you must stop as gently as possible, and without making any noise; the horses will then suffer themselves to be taken without any opposition. It is called in French haraux, and count Saxe is the only author that mentions it.

Decoy, among fowlers, a place made for catching wild-fowl. A decoy is generally made where there is a large pond surrounded with wood, and beyond that a marshy and uncultivated country: if the piece of water is not thus surrounded, it will be attended with noise and other accidents which may be expected to frighten the wild-fowl from a quiet haunt, where they mean to sleep, in the day-time, in security. If these noises or disturbances are wilful, it has been held that an action will lie against the disturber. As soon as the evening sets in, the decoy rises, and the wild-fowl feed during the night. If the evening is still, the noise of their wings during their flight is heard at a very great distance; and is a pleasing, though rather melancholy, sound. This rising of the decoy in the evening is, in Somersetshire, called *radding*.

The decoy-ducks are fed with hempseed, which is thrown over the screens in small quantities, to bring them forwards into the pipes or canals, and to allure the wild-fowl to follow, as this seed is so light as to float. There are several pipes, as they are called, which lead up a narrow ditch that closes at last with a funnel-net. Over these pipes (which grow narrow from their first entrance) is a continued arch of netting suspended on hoops. It is necessary to have a pipe or ditch for almost every wind that can blow, as upon this circumstance it depends which pipe the fowl will take to; and the decoy-man always keeps on the leeward side of the ducks, to prevent his scent reaching their sagacious nostrils. All along each pipe, at intervals, are placed screens made of reeds, which are so situated that it is impossible the wild-fowl should see the decoy-man before they have passed on towards the end of the pipe, where the purse-net is placed. The inducement to the wild-fowl to go up one of these pipes is, because the decoy-ducks trained to this lead the way, either after hearing the whistle of the decoy-man, or enticed by the hemp-seed; the latter will dive under water, whilst the wild-fowl fly on and are taken in the purse.

It often happens, however, that the wild-fowl are in such a state of sleepiness and dozing, that they will not follow the decoy-ducks. Use is then generally made of a dog that is taught his lesson: he passes backwards and forwards between the red-screens (in which are little holes, both for the decoy-man to see, and the little dog to pass through); this attracts the eye of the wild-fowl, who, not choosing to be interrupted, advance towards the small and contemptible animal, that they may drive him away. The dog all the time, by the direction of the decoy-man, plays among the screens of reeds, nearer and nearer the purse-net; till at last perhaps the decoy-man appears behind a screen, and the wild-fowl

not daring to pass by him in return, nor being able to escape upwards on account of the net-covering, rush on into the purse-net. Sometimes the dog will not attract their attention if a red handkerchief, or something very singular, is not put about him.

The general season for catching fowl in decoys is from the end of October till February; the taking of them earlier is prohibited by an act 10 Geo. II. c. 32. which forbids it from June 1st to October 1st, under the penalty of five shillings for each bird destroyed within that space.

The Lincolnshire decoys are commonly let at a certain annual rent, from five to twenty pounds a year; and there is one in Somersetshire that pays thirty pounds. The former contribute principally to supply the markets in London. Amazing numbers of ducks, wigeons, and teal, are taken: by an account of the number caught a few winters past, in one season, and in only ten decoys, in the neighbourhood of Wainfleet, it appeared to amount to 31,200, in which are included several other species of ducks. It is also to be observed, that in the above particular a couple of wigeon or teal are reckoned but as one, and consequently sell but at half-price of the ducks.

It was customary formerly to have in the fens an annual driving of the young ducks before they took wing. Numbers of people assembled, who beat a vast tract, and forced the birds into a net placed at the spot where the sport was to terminate. Thus a hundred and fifty dozens have been taken at once; but this practice, being supposed detrimental, has been abolished by act of parliament.

DECRETE, in the law of Scotland, a final decree or judgment of the lords of session, from which an appeal lies only to parliament, where we find them but two often reversed, a circumstance surely not much to the honour of the august bench whence the appeal lies.

DECREMENT, in heraldry, signifies the wane of the moon from the full to the new.

DECREPITATION. See CHEMISTRY.

DECRETAL, in the canon-law, a letter of a pope determining some point or question in the ecclesiastical law. The decretals composed the second part of the canon-law. The first genuine one acknowledged by all the learned as such, is a letter of pope Siricius, written in the year 385, to Himerus bishop of Tarragona in Spain, concerning some disorders which had crept into the churches of Spain. Gratian published a collection of decretals, containing all the ordinances made by the popes till the year 1150. Gregory IX. in 1227, following the example of Theodosius and Justinian, formed a constitution of his own; collecting into one body all the decisions, and all the canons, which served to advance the papal power: which collection of decretals was called the Pentateuch, because it contained five books.

[DECUMARIA, in botany, a genus of the monogynia order, in the dodecandria class of plants. The calyx is from eight to ten phyllous; the corolla eight or ten petalled, frutescent; capsule seven celled, polyspermous. There are two species, natives of Carolina and Pennsylvania: 1. the D. harbara, or climbing; 2. D. sarmentosa, or running decumaria. (*a*)

DECURIO, in Roman antiquity, a commander of ten men in the army, or the chief of a decury.

DECUSSORIUM, a surgeon's instrument, which, by pressing gently on the dura mater, causes an evacuation of the pus collected between the cranium and the before-mentioned membrane, through the perforation made by the trepan.

DEDIMUS, POTESTATEM, in law, a commission granted to one or more persons, for the forwarding and despatching some act appertaining to a judge, or some court; as to take answers in chancery, depositions of witnesses in a cause depending in that court, and levy a fine in the common pleas, &c. where persons live in the country, or cannot travel.

DEED, is a written contract sealed and delivered. It must be written before the sealing and delivery, otherwise it is no deed; and after it is once formally executed by the parties, nothing can be added or interlined; and therefore, if a deed is sealed and delivered with a blank left for the sum, which the obligee fills up after sealing and delivery, this will make the deed void.

A deed must be made by parties capable of contracting, and upon a good consideration; and the subject must be legally and formally set out.

The formal parts of a deed are:

The premises, containing the number, names, additions, and titles, of the parties.

The habendum, which determines the estate and interest intended to be granted by the deed.

The reddendum, or reservation, whereby the grantor reserves to himself something out of the thing granted.

A condition, which is a clause of contingency, on the happening of which the estate granted may be defeated.

The warranty, whereby the grantor, for himself and heirs, warrants or secures to the grantee the estate so granted.

The covenants, which are clauses of agreement contained in the deed, whereby the contracting parties stipulate for the truth of certain facts, or bind themselves to the performance of some specific acts.

The conclusion, which mentions the execution and date of the deed, or the time of its being given or executed, either expressly, or with reference to some day and year before mentioned.

A deed may be either an indenture or a deed-poll. The former derives its name from being indented or cut in an uneven manner, so as to tally with the counterparts, of which there ought to be as many as there are parties; the latter, or deed-poll, of which there is one part only, is so called from its being polled or shaved quite even.

A deed is the most solemn act of law which a man can perform with respect to the disposition of his property, and therefore no person shall be permitted to aver or prove any thing against his own deed.

All the parts of a deed indented, constitute in law but one entire deed; but every part has the same operative force as all the parts taken together; and they are deemed the mutual or reciprocal acts of either of the parties; who may be bound by either part of the same, and the words of the indenture may be considered as the words of either party.

If the name of baptism or surname of a party to a deed be mistaken, as John for Thomas, &c. this has been held to be dangerous. 2 Bulst. 70.

But any mistake as spelling, &c. not deviating from the substance of the deed, will not render it void.

If a man gets another name in common esteem than his right name, any deed made to him under such name will be vallid.

Every deed must be founded upon good and sufficient consideration; not upon an usurious contract, nor upon fraud or collusion, either to deceive bona fide purchasers, or just and lawful creditors; any of which considerations will vacate the deed, and subject the parties to forfeiture, and in some cases to imprisonment.

A deed also without any consideration is void, and is construed to enure only to the benefit of the party making it.

Considerations may be express or implied. An express consideration, is where a man contracts to do a certain act for a certain sum of money, or other equivalent act; and an implied consideration is, when it may be enforced by law; thus if a person does any work, or receives any goods from another, the law implies a consideration, which it will enforce although there was no specific agreement for remuneration.

The written matter of a deed must be set forth in a legal and orderly manner, so that there are words sufficient to explain the meaning of the parties, and at the same time to bind them to the execution of their contract; and of this sufficiency the courts of law are to determine. Although it is not indeed absolutely necessary in law, to have all the formal words which are usually drawn out in deeds, provided there are sufficient words legally and clearly to explain the meaning of the parties; yet as these formal or orderly parts are calculated to convey the meaning of the parties in the most clear, distinct, and effectual manner, and have been well considered and sanctioned by the wisdom of successive ages, it is prudent not to depart from them without good reason, and the most urgent necessity.

The force and effect which the law gives to a deed under seal, cannot exist, unless such deed is executed by the party himself, or by another for him, in his presence, or with his direction; or in his absence by an agent authorised so to do, by another deed also under seal, and in every such case the deed must be made and executed in the name of the principal.

A deed takes effect only from the day of delivery: and therefore if it has no date, or a date impossible, the delivery will in all cases ascertain the date of it; and if another party seals the deed, yet if the party delivers it himself he adopts the sealing and signing, and by such delivery makes them both his own.

The delivery of a deed may be alleged at any time after the date; but unless it is sealed, and regularly delivered, it is no deed.

Another requisite of a deed is, that it be properly witnessed or attested; the attestation is, however, necessary rather for preserving the evidence, than as intrinsically essential to the validity of the instrument.

There are four principles adopted by the courts of law for the exposition of deeds, viz.

That they be beneficial to the grantee, or person in whose favour they are intended to operate.

That where the words may be employed to some interest, they shall not be void.

That the words be construed according to the meaning of the parties, and not otherwise; and the intent of the parties shall be carried into effect, provided such intent can possibly stand at law.

That they are to be consonant to the rules of law; and deeds shall be expounded reasonably without injury to the grantor, and to the greatest advantage of the grantee. Deeds are further expounded upon the whole; and if the second part contradicts the first, such second part shall be void; but if the latter expounds or explains the former, which it may, both parts may stand.

In construction of law the first deed and the last will stand in force; and where a deed is by indenture between parties, none can have an action upon such deed, but the person who is a party to it. In a deed-poll however, one person may covenant with another who is not a party, to do certain acts, for the non-performance of which he may bring his action.

Where a man justifies title under any deed, he ought to produce that deed; if it be alledged in pleading, it must be produced to the court, that it may determine whether the deed contains sufficient words to make a valid contract.

DEED-POLL, is a deed polled, or shaved, quite even; in contradistinction from an indenture, which is cut unevenly, and answerable to another writing that comprehends the same words. A deed-poll is properly single, or of one part, and is intended for the use of feoffee, grantee, or lessee; an indenture always consists of two or more parts and parties. Every deed that is pleaded, shall be intended to be a deed-poll, unless it is alleged to be indented.

DEEMSTERS, or *demsters*. All controversies in the Isle of Man are decided without process, writings, or any charges, by certain judges chosen yearly from among themselves, called deemsters; there being two of them for each division of the Island: they sit as judges in all courts, either for life or property; and with the advice of the twenty-four keys, declare what is law in uncommon emergencies.

DEEP SEA-LINE, or *dip sea-line*, in the sea-language, a small line to sound with: some a hundred and fifty fathoms long, with a hollow plummet at the head, and tallow put into it, to bring up stones, gravel, sand, shells, and the like, from the bottom, in order to know the differences of the ground; which being entered from time to time in their books, by comparing of observations, they guess by their soundings, &c. what coasts they are on, though they cannot see land.

DEER. See CERVUS.

DEER-STEALERS, in England, are punishable by various laws and statutes, made from time to time. Any offender convicted of deer-stealing, before a judge of gaol-delivery, may be transported, by 5 Geo. I. c. 28. And it is felony for persons to appear armed and disguised in a forest or park, and hunt or kill the deer, by 6 Geo. I. c. 22.

DE ESSENDO QUIETEM DE TOLONIO, in law, a writ which lies for those who, by privilege, are free from the payment of toll.

DE EXPENSIS MILITUM, in law, an ancient writ, commanding the sheriff to levy the expenses of a knight of the shire, for his attendance in parliament, being four

shillings a day. There is also another writ of the like nature, *de expensis civium et burgensium*, for levying two shillings a day for the expenses of every citizen and burgess of parliament.

DE FACTO, something actually in fact, or existing; in contradistinction to de jure, where a thing is only so in justice, but not in fact: as a king de facto is a person that is in actual possession of a crown, but has no legal right to the same; and a king de jure is the person who has just right to the crown, though he is out of possession of it.

DEFAMATION, the offence of speaking slanderous words of another; and where any person circulates any report injurious to the credit or character of another, the party injured may bring an action to recover damages proportioned to the injury he has sustained; but it is incumbent upon the party to prove he sustained an injury, to entitle him to damages. In some cases however, as for words spoken which by law are in themselves actionable, as calling a tradesman a bankrupt, cheat, or swindler, &c. there is no occasion to prove any particular damage; but the plaintiff must be particularly attentive to state words precisely as they were spoken, otherwise he will be nonsuited.

DEFAULT, is commonly taken for non-appearance in court at a day assigned. If a plaintiff make default in appearance in a trial at law, he will be nonsuited; and where defendant makes a default, judgment shall be had against him by default.

Default in criminal cases. If an offender, being indicted, appears at the capias, and pleads to issue, and is let to bail to attend his trial, and then make default; here the inquest, in case of felony, shall never be taken by default; but a capias ad audiendum juratum shall issue, and if the party is not taken, an exigent; and if he appear on that writ, and then makes default, an exigi facias de novo may be granted: but where, upon the capias on exigent, the sheriff returns cepi corpus, and at the day has not his body, the sheriff shall be punished; but no new exigent awarded, because in custody of record. 2 H. H. 202.

Default of jurors. If jurors make default in their appearance for trying of causes, they shall forfeit their issues, unless they have any reasonable excuse proved by witness, in which case the justices may discharge the issues for default. Stat. 35 H. VIII. c. 6.

DEFEASANCE, a condition relating to a deed; as to a recognizance or statute, which being performed by the recognizor, the deed is defeated, and made void, as if it had never been done. The difference between a proviso or a condition in a deed, and a defeasance, is, that the condition is annexed to, or inserted in, the deed or grant; and a defeasance is a deed by itself concluded and agreed on between the parties, and having relation to another deed.

DEFENCE, in fortification, all sorts of works that cover and defend the opposite posts; as flanks, casemates, parapets, and faussebrays. It is almost impossible to fix the miner to the face of a bastion, till the defences of the opposite one are ruined, that is, till the parapet of its flank is beaten down, and the cannon, in all parts that can fire upon that face which is attacked, are dismounted.

Defence, *line of*, a supposed line drawn from the angle of the curtin, or from any other part in the curtin, to the flanked angle of the opposite bastion. A line of defence represents the flight of a musquet-ball from the place where the musqueteers stand, to scour the face of the bastion, and ought never to exceed the reach of a musquet. It is either fichant or rasant: the first is when it is drawn from the angle of the curtin to the flanked angle; the last when it is drawn from a point in the curtin, raising the face of the bastion.

Defence, in law, signifies a plea, or what the defendant ought to make after the plaintiff's count, or declaration, viz. that he defends all the wrong, force, and damages, where and when he ought, &c. If the defendant would plead to the jurisdiction, he must omit the words "where and when he ought;" and if he would show any disability in the plaintiff, and demand judgment if the plaintiff shall be answered, then he ought to omit the defence of the damage. There is a full defence usually in personal actions.

DEFERENTIA VASA. See Anatomy.

DEFICIENT NUMBERS, those whose parts or multiples added together fall short of the integer, of which they are the parts: such is 8, its parts, 1, 2, 4, making only 7. See the article Number.

DEFILE, in fortification, a straight narrow passage, through which a company of horse or foot can pass only in file, by making a small front; so that the enemy may take an opportunity to stop their march, and to charge them with so much the more advantage, as those in the front and rear cannot reciprocally come to the relief of one another.

To Defile, is to reduce an army to a small front, in order to march through a defile.

DEFINITION, in rhetoric, is described by Cicero, a short comprehensive explanation.

The special rules for a good definition are these: 1. A definition must be universal, or adequate, that is, it must agree to all the particular species or individuals that are included under the same idea. 2. It must be proper, and peculiar to the thing defined, and agree to that alone. These two rules being observed will always render a definition reciprocal with the thing defined, that is, the definition may be used in the place of the thing defined: or they may be mutually affirmed concerning each other. 3. A definition should be clear and plain; and indeed it is a general rule concerning the definition both of names and things, that no word should be used in either of them which has any difficulty in it, unless it has been before defined. 4. A definition should be short, so that it must have no tautology in it, nor any words superfluous. 5. Neither the thing defined, nor a mere synonymous name should make any part of the definition.

DEFLAGRATION. See Chemistry.

DEFOLIATION (from *de*, and *folium* a leaf), the fall of the leaves; a term opposed to frondescentia, the annual renovation of the leaves, produced by the unfolding of the buds in spring. Most plants in cold and temperate climates shed their leaves every year: this happens in autumn, and is generally announced by the flowering of the common meadow-saffron. The term is

only applied to trees and shrubs; for herbs perish down to the root every year, losing stem, leaves, and all.

All plants do not drop their leaves at the same time. Among large trees, the ash and the walnut, although latest in unfolding are soonest divested of them: the latter seldom carries its leaves above five months. On the oak and hornbeam the leaves die and wither as soon as the cold commences; but remain attached to the branches till they are pushed off by the new ones, which unfold themselves in the following spring. These trees are doubtless a kind of half evergreens: the leaves are probably destroyed only by cold; and perhaps would continue longer on the plant but for the force of the spring-sap, joined to the moisture.

In mild and dry seasons the lilac, privet, yellow jessamine of the woods, and maple of Crete, preserve their leaves green until spring, and do not drop them till the new leaves are beginning to appear. The fig-tree, and many other trees that grow between the tropics, are of this particular class of ever-greens. The trees in Egypt, says doctor Hasselquist, cast their leaves in the end of December and the beginning of January, having young leaves ready before all the old ones are fallen off; and to forward this operation of nature few of the trees have buds: the scycamore and willow, indeed, have some, but with few and quite loose stipulæ or scales. Nature did not imagine buds so necessary in the southern as in the northern countries: this occasions a great difference between them.

Lastly, some trees and shrubs preserve their leaves constantly through the whole year, and are not in the least influenced by clemency or inclemency of seasons. Such are the firs, juniper, yew, cedar, cypress, and many other tress, hence denominated evergreens. These preserve their old leaves a long time after the formation of the new, and do not drop them at any determinate time. In general, the leaves of evergreens are harder, and less succulent, than those which are renewed annually. These trees are generally natives of warm climates; as the alaternuses of France and Italy, the evergreen oak of Portugal and Suabia.

The following table, respecting the mean times in which different trees shed their leaves, is founded upon observation:

	Generally shed their leaves about
Gooseberry-tree and blad-der-sena,	Oct. 1.
Walnut and ash, - - -	—— 15.
Almond-tree, horse-chesnut, and lime-tree, - - - - -	—— 20.
Maple, hazel-nut, black poplar, and aspen-tree. - - - - -	—— 25.
Birch, plane-tree, mountain osier, false acacia, pear, and apple-tree,	Nov. 1.
Vine, mulberry, fig, sumac, and angelica-tree, - - - - -	——10.
Elm-tree and willow, - -	——15.
Apricot and elder-trees, - -	——20.

It deserves to be remarked, that an evergreen tree grafted upon a deciduous, determines the latter to retain its leaves. This observation is confirmed by repeated experiments, particularly by grafting the laurel, or cherry-bay, an evergreen, on the common cherry; and the ilex, or evergreen oak, on the oak.

DEFORCEMENT, in law, the casting any one out of his land, or a withholding of lands and tenements by force from the right owner.

DEFORCEMENT, in the law of Scotland, is used for resisting, or offering violence to the officers of the law, while they are actually employed in the exercise of their functions, by putting its orders and sentences in execution. The punishment of this crime is confiscation of moveables, joined with some arbitrary punishment, as fine, imprisonment, banishment, or corporal pains, according to the degree of violence, and other circumstances which aggravate the crime.

DEFORCEOR, in law, is a person that overcomes and casts forth another from his lands and tenements by force, and differs from a disseisor on this account: 1. That a man may be disseised without force. 2. A man may deforce another that never was in possession; as where many have a right to lands, as common heirs, and one of them enters and keeps out the rest. A deforceor likewise differs from an intruder, who is made by a wrongful entry only into land, &c. void of a possessor, whilst a deforceor is he that holds out against the right heir.

DEFTERDAR, or *deftardar*, in the Turkish and Persian polity, an officer of state, answering to our lord treasurer, who appoints deputies in every province.

DEGLUTITION, in medicine, the act of swallowing the food: performed by means of the tongue driving the aliment into the œsophagus, which, by the contraction of the sphincter, protrudes the contents downwards.

DEGRADATION, a punishment of delinquent ecclesiastics. The canon-law distinguishes it into two sorts: the one summary, by word only; the other solemn, by stripping the person degraded of those ornaments and rights which are the ensigns of his order or degree. The canonists likewise distinguish degradation from deposition; understanding by the latter the depriving a man of his clerical orders, but by the former only the removing him from his rank or degree. In the ancient primitive church, degrading a clergyman was reducing him to the state and communion of laymen. The full import of the phrase, however, is the depriving him of his orders, and reducing him to the simple condition of a layman; a punishment inflicted for several offences, as adultery, theft, or fraud: and clergymen thus reduced were seldom allowed to recover their ancient station, except upon some great necessity, or very pressing reason. Degradation in the Romish church is attended with a great deal of ceremony. The offender is stripped of his pontifical vestments, and at the same time the person who degrades him scrapes his fingers with a knife, or a little piece of glass, declaring to him that the power of consecrating, blessing, and sanctifying, is taken from him: he erases the marks of the tonsure in the same manner, which a barber completes by shaving his head all over.

DEGRADATION, in painting, expresses the lessening the appearance of distant objects in a landscape, in the same manner as they would appear to an eye placed at that distance from them. See the articles PERSPECTIVE and PAINTING.

DEGRADED CROSS, in heraldry, a cross divided

into steps at each end, diminishing as they ascend towards the centre, called by the French peronne'e.

DEGREE, in geometry, a division of a circle, including a three hundred and sixtieth part of its circumference.

Every circle is supposed to be divided into three hundred and sixty parts, called degrees, and each degree divided into sixty other parts, called minutes; each of these minutes being again divided into sixty seconds, each second into thirds, and each third into fourths, and so on. See the articles MINUTE, SECOND, &c.

By this means no more degrees or parts are reckoned in the greatest circle than in the least that is; and therefore if the same angle at the centre be subtended by two concentrical arches, as many degrees are counted in the one as in the other; for these two arches have the same proportion to their whole peripheries.

A degree of the meridian on the surface of the globe is variously determined by various observers.

Ptolemy fixes the degree at 68¾ Arabic miles, counting 7½ stadia to a mile. The Arabs themselves, who made a computation of the diameter of the earth, by measuring the distance of two places under the same meridian, in the plains of Senaar, by order of Almamon, make it only 56 miles. Kepler, determining the diameter of the earth by the distance of two mountains, makes a degree 13 German miles; but his method is far from being accurate. Snell, seeking the diameter of the earth from the distance between two parallels of the equator, finds the quantity of a degree by one method 57,064 Paris toises, or 342,384 feet; by another method 57,057 Paris toises, or 342,342 feet. The mean between which two numbers M. Picard found by mensuration, in 1669, from Amiens to Malvoisin, the most certain; and he makes the quantity of a degree 57,060 toises, or 342,360 feet. However, M. Cassini, at the king's command, in the year 1700, repeated the same labour; and measuring the space of 6° 18′, from the observatory at Paris, along the meridian, to the city of Collioure in Roussillon, that the greatness of the interval might diminish the error, found the length of the degree equal to 57,292 toises, or 343,742 Paris feet, amounting to 365,184 English feet.

And with this account nearly agrees that of Norwood, of England, who, about the year 1635, measured the distance between London and York, and found that distance 905,761 English feet; the difference of latitude being 2° 28′, hence he determined the quantity of one degree at 367,196 English feet, or 57,300 Paris toises, or 69 miles, 288 yards.

M. Cassini, the son, completed the work of measuring the whole arc of the meridian through France, in 1718. For this purpose he divided the meridian of France into two arcs, which he measured separately. The one from Paris to Collioure gave him 57,097 toises; the other, from Paris to Dunkirk, 56,960; and the whole arc from Dunkirk to Collioure 57,060; the same as M. Picard's.

M. Muschenbroek, in 1700, resolving to correct the errors of Snell, found by particular observations, that the degree between Alcmaer and Bergen-op-zoon contained 57,033 toises.

Messieurs Maupertuis, Clairaut, Camus, Monnier, and Outhier, of France, were sent on a northern expedition; and began their operations, assisted by M. Celsius, an eminent astronomer of Sweden, in Swedish Lapland, in July 1736, and finished them by the end of May following. They obtained the measure of that degree, whose middle point was in lat. 66° 20′ north, and found it 57,439 toises, when reduced to the level of the sea. About the same time another company of philosophers was sent to South America, viz. messieurs Godin, Bouguer, and Condamine, of France, to whom were joined don Jorge Juan, and don Antonio de Ulloa, of Spain. They left Europe in 1735, and began their operations in the province of Quito, in Peru, about October 1736, and finished them, after many interruptions, about eight years after. The Spanish gentlemen published a separate account, and assigned for the measure of a degree of the meridian at the equator 56,768 toises. M. Bouguer makes it 56,753 toises, when reduced to the level of the sea; and M. Condamine states it at 56,749 toises.

M. La Caille, being at the Cape of Good Hope in 1752, found the length of a degree of the meridian in lat. 33° 18′ 30″ south, to be 57,037 toises. In 1755 father Boscovich found the length of a degree in lat. 43° north to be about 56,972 toises, as measured between Rome and Rimini, in Italy. In the year 1740 messrs. Cassini and La Caille again examined the former measures in France; and after making all the necessary corrections, found the measure of a degree, whose middle point is in lat. of 49° 22′ north, to be 57,074 toises; and in the lat. of 45° it was 57,050 toises.

In 1764 F. Beccaria completed the measurement of a portion of the meridian near Turin; from which it is deduced that the length of a degree, whose middle lat. is 44° 44′ north, is 57,024 Paris toises.

At Vienna three degrees of the meridian were measured; and the medium for the latitude of 47° 40′ north may be taken at 57,091 Paris toises. See an account of this measurement in the Phil. Trans. 1768.

Finally, in the same volume is an account of the measurement of a part of the meridian in Maryland and Pennsylvania, 1766, by messieurs Mason and Dixon; from which it follows that the length of a degree whose middle point is 39° 12′ north, was 363,763 English feet, or 56.904½ Paris toises.

Hence from the whole we may collect the following table of the principal measures of a degree in different parts of the earth, as measured by different persons, viz.

Mean Latitude			Length of a Degree in Paris toises	Names of the Measurers.	Years of Measurement.
66°	20′	N	57422	Maupertuis, &c.	1736 and 1737
49	23	N	57074	Maupertuis, &c. and Cassini	1739 and 1740
47	40	N	57091	Liesganig	1766
45	0	N	57028	Cassini	1739 and 1740
44	44	N	57069	Beccaria	1760 to 1764
43	0	N	56979	Boscovich and Le Maire	1752
39	12	N	56888	Mason & Dixon	1764 to 1768
0	0	N	56750	Bouguer and Condamine	1736 to 1744
33	18	S	57037	La Caille	1752

The method of obtaining the length of a degree of the terrestrial meridian, is to measure a certain distance upon it by a series of triangles, whose angles may be found by actual observation, connected with a base whose length may be taken by an actual survey or otherwise; and then to observe the different altitudes of some star at the two extremities of that distance, which gives the difference of latitude between them: then, by proportion, as this difference of latitude is to one degree, so is the measured length to the length of one degree of the meridian sought. This method was first practised by Erastothenes, in Egypt.

DEGREE *of longitude*, is the space between two meridians that make an angle of 1° with each other at the poles; the quantity or length of which is variable, according to the latitude, being every where as the cosine of the latitude; viz. as the cosine of one lat. is to the cosine of another, so is the length of a degree in the former lat. to that in the latter; and from this theorem is computed the following table of the length of a degree of long. in different latitudes, supposing the earth to be a globe.

Note. This table is computed on the supposition, that the degrees of the equator are equal to those of the meridian at the medium latitude of 45°, which length is $69\frac{1}{17}$ English miles.

The expressions latitude and longitude are borrowed from the ancients, who happened to be acquainted with a much larger extent of earth in the direction east and west than in that of north and south; the former of which therefore passed, with them, for the length of the earth, or longitude; and the latter for the breadth, or shorter dimension, viz. the lititude.

Deg. lat.	Eng. miles.	Deg. lat.	Eng. miles.	Deg. lat.	Eng. miles.
0	69.07	31	59.13	61	33.45
1	69.06	32	58.51	62	32.40
2	69.03	33	57.87	63	31.33

Our theory of navigation being founded upon an hypothesis of the degrees of latitude being all equal, must of consequence be very erroneous, wherefore we here insert a table of the degrees in the quadrantal arch of the meridian, both in the sphere and spheriod, with their differences, as calculated by the Rev. Mr. Murdoch.

A TABLE of Arches of the Meridian to the Spheriod and Sphere, in minutes of the Equator.

Degr.	Spheroid.	Sphere.	Diff.
1	58.7	60.0	1.3
2	117.3	120.0	2.7

DEGREE, in the civil and canon law, denotes an interval in kinship by which proximity and remoteness of blood are computed. In computing degrees of consanguinity, the rule of the civil law is universal, either in the direct or collateral, otherwise called the oblique line; for as many generations as there are, so many degrees there are likewise. But in the canon law, the rule is different for the oblique line. And here a distinction is made between the equal and the unequal oblique line. In the first case the rule is, as many degrees as the persons allied are distant from the common stock, so many they are distant from one another. In the other case the rule is, as many degrees as the most remote is distant from the common stock, so many the persons are distant from one another. Hence the sister of a person's grand-father by the civil law is distant from that person in the fourth degree; whereas, by the canon law, she is only in the third degree.

DEGREE, *theoretical*, in music, the difference of position or elevation between any two notes. There are conjunct and disjunct degrees. When two notes are situated so as to form the interval of a second, the degree is said to be conjunct; and when they form a third, or any greater interval, the degree is called disjunct.

DEGREE, in universities, denotes a kind of rank or distinction conferred on the students or members as a testimony of their proficiency in the arts or sciences, and entitling them to certain privileges. The degrees are much the same in all universities, but the laws and the previous discipline or exercise differ. The degrees are batchelor, master, and doctor; instead of which last, in some foreign universities, they have licentiate.

With regard to obtaining degrees at Oxford and Cambridge, matters are nearly on the same footing.

To pass bachelor of divinity, the candidate must have been seven years master of arts: he must have opposed a bachelor of divinity act, and preached before the university once in Latin and once in English.

DELEGATES, court of, is so called, because by stat. 26 H. VIII. c. 19, the judges are delegated by the king's commission under the great seal, to hear and determine appeals in the three following cases: 1. Where a sentence is given in any ecclesiastical cause by the archbishop or his official. 2. When a sentence is given in any ecclesiastical cause in the places exempt. 3. When a sentence is given in the admiral's court, in suits civil and marine, by order of the civil law. This commission is usually filled with lords spiritual and temporal, judges of the courts at Westminster, and doctors of the civil law. 4 Inst. 339.

DELEGATION, in the civil law, is a kind of nomination, by which a debtor appoints one that is debtor to him, to answer a creditor in his place. This delegation differs from transferring, or translation, in this; that three persons intervene in a delegation, viz. the creditor, the debtor, and a third indebted to the debtor; whereas in a transfer, it is enough that the transferer and the transferee be present.

DELF, from to delve, or dig, denotes a quarry or mine, where either stone or coal is dug; but is more particularly used for the veins of coal lying under ground, before it is dug up. A delf, or delve of coals, also denotes a certain quantity when dug.

DELF, in heraldry, is by some supposed to represent a square rod or turf, and to be so called from delving, or digging.

DELFT *ware*, a kind of pottery of baked earth, covered with an enamel or white glazing, which gives it the appearance and neatness of porcelain. Some kinds of this enamelled pottery differ much from others, either

in their sustaining sudden heat without breaking, or in the beauty and regularity of their forms, of their enamel, and of the painting with which they are ornamented. In general, the fine and beautiful enamelled ware, which approaches the nearest to porcelain in external appearance, is at the same time that which least resists a brisk fire. Again, those which sustain a sudden heat are coarse, and resemble common pottery.

The basis of this pottery is clay, which is mixed, when too fat, with such a quantity of sand, that the earth shall preserve enough of its ductility to be worked, moulded, and turned easily; and yet that its fatness shall be sufficiently taken from it, that it may not crack or shrink too much in drying or in baking. Vessels formed of this earth must be dried very gently, to avoid cracking. They are then to be placed in a furnace, to receive a slight baking, which is only meant to give them a certain consistence or hardness. And lastly, they are to be covered with an enamel or glazing, which is done by putting upon the vessel thus prepared the enamel, which has been ground very fine, and diluted with water.

As vessels on which the enamel is applied, are but slightly baked, they readily imbibe the water in which the enamel is suspended, and a layer of this enamel adheres to their surface. These vessels may then be painted with colours composed of metallic calces, mixed and ground with fusible glass. When they are become perfectly dry, they are to be placed in the furnace, included in cases of baked earth called seggars, and exposed to a heat capable of fusing uniformly the enamel which covers them. The heat given to fuse the enamel being much stronger than that which was applied at first to give some consistence to the ware, is also the heat necessary to complete the baking of it. The furnace and colours used for painting this ware, are the same as those employed for porcelain. Delft-ware is not so much used in England as formerly.

DELIAC, or DELIAN PROBLEM, a problem much celebrated in the writings of the ancients, concerning the duplication of the cube. See CUBE.

DELIMA, in botany, a genus of plants belonging to the polyandria monogynia class, with an elongated style: it has no flower-petals; the cup consists of five leaves; the fruit is a bivalve capsule, and contains two seeds. There is one species.

DELIRIUM. See MEDICINE.

DELIVERY. See MIDWIFERY.

DELPHINIUM, DOLPHIN-FLOWER, or LARKSPUR, a genus of the trigynia order, in the polyandria class of plants, and in the natural method ranking under the 26th order, multisiliquæ. There is no calyx; the petals are five; the nectarium bifid, and horned behind; the siliquæ three or one. There are 11 species; four are cultivated in gardens. Two of these are annual, and two perennial: they are herbaceous plants of upright growth, rising from 18 inches to 4 feet in height, garnished with finely divided leaves, and terminated by long spikes of pentapetalous flowers, of blue, red, white, or violet colours. One annual species, the consolida, is found wild in several parts of Britain, and grows in corn-fields. According to Dr. Withering, the expressed juice of the petals, with a little alum, makes a good blue ink. The seeds are acrid and poisonous. When cultivated, the blossoms often become double. Sheep and goats eat this plant; horses are not fond of it; cows and swine refuse it.

DELPHINUS, or DOLPHIN, a genus of fishes belonging to the order of cete. There are three species:

1. The delphinus, delphis, or dolphin. Historians and philosophers seem to have contended who should invent most fables concerning this fish. It was consecrated to the gods, was celebrated in the earliest time for its fondness of the human race, was honoured with the title of the sacred fish, and distinguished by that of philanthropist. At present the appearance of this fish, and the porpesse, are far from being esteemed favourable omens by the seamen; for their boundings, springs, and frolics, in the water, are held to be certain signs of an approaching gale. It is from their leaps out of that element that they assume a temporary form that is not natural to them; but which the old painters and sculptors have almost always given them. A dolphin is scarcely ever exhibited by the ancients in a straight shape, but almost always incurvated: such are those on the coin of Alexander the Great, which is preserved by Belon, as well as on several other pieces of antiquity; and the poets describe them much in the same manner. The natural shape of the dolphin, however, is almost straight, the back being very slightly incurvated, and the body slender; the nose is long, narrow, and pointed, not much unlike the beak of some birds, for which reason the French call it l'oie-de-mer. It has in all 40 teeth, 21 in the upper jaw and 19 in the lower; a little above an inch long, conic at their upper end, sharp-pointed, bending a little in. They are placed at small distances from each other; so that when the mouth is shut, the teeth of both jaws lock into one another; the spout-hole is placed in the middle of the head; the tail is semilunar; the skin is smooth, the colour of the back and sides dusky, the belly whitish; it swims with great swiftness, and its prey is fish. It was formerly reckoned a great delicacy. This species of dolphin, however, must not be confounded with that to which seamen give the name; the latter being quite another kind of fish, the coryphæna hippuris of Linnæus, and the dorado of the Portuguese.

2. The phocæna, or porpesse. This species is found in vast multitudes in all parts of the British seas; but in greatest numbers at the time when fish of passage appear, such as mackarel, herrings, and salmon, which they pursue up the bays with the same eagerness as a dog does a hare. In some places they almost darken the sea, as they rise above water to take breath: but porpesses not only seek for prey near the surface, but often descend to the bottom in search of sand-eels and sea-worms, which they root out of the sand with their noses. Their bodies are very thick towards the head, but grow slender towards the tail. The nose projects a little, is much shorter than that of the dolphin, and is furnished with very strong muscles, which enable it the readier to turn up the sand. The colour of the porpesse is generally black, and the belly whitish; but they sometimes vary. In the river St. Lawrence there is a white kind; and Dr. Borlase, in his voyage to the Scilly isles, observed a small species of cetaceous fish, which he calls thornbacks, from their broad and sharp fin on the back. Some of these were brown, some quite white, others spotted: but whether they were only a variety of this fish, or whether

they were small grampuses, which are also spotted, we cannot determine. The porpesse is remarkable for the vast quantity of fat that surrounds the body, which yields a great quantity of excellent oil. From this, or from their rooting like swine, they are called in many places sea-hogs. This was once a royal dish, even so late as the reign of Henry VIII. and from its magnitude must have held a very respectable station at the table; for in a household-book of that prince, extracts of which are published in the third volume of the Archæologia, it is ordered, that if a porpesse should be too big for a horse-load, allowance should be made to the purveyor. This fish continued in vogue even in the reign of Elizabeth.

3. The orca, or grampus, is found from the length of 15 feet to that of 25. It is remarkably thick in proportion to its length; one of 18 feet being in the thickest place 10 feet diameter. With reason then did Pliny call this "an immense heap of flesh armed with dreadful teeth." It is extremely voracious; and will not even spare the porpesse, a congenerous fish. It is said to be a great enemy to the whale, and that it will fasten on it like a dog on a bull, till the animal roars with pain. The nose is flat, and turns up at the end. There are 30 teeth in each jaw; those before are blunt, round, and slender; the farthest sharp and thick: between each is a space adapted to receive the teeth of the opposite jaw when the mouth is closed. The spout-hole is in the top of the neck. The colour of the back is black, but on each shoulder is a large white spot; the sides marbled with black and white; the belly of a snowy whiteness. These fishes sometimes appear on our coasts, but are found in much greater numbers off the North Cape in Norway, whence they are called the north-capers. These and all other whales are observed to swim against the wind; and to be much disturbed, and tumble about with unusual violence, at the approach of a storm.

4. The leucas, a species called by the Germans and Russians "white fish." The body is oblong, and rather slender, tapering from the back (which is a little elevated) to the tail. It is quite destitute of the dorsal fin. Its length is from 12 to 18 feet. It makes great use of its tail in swimming; for it bends that part under it, as a lobster does its tail, and works it with such force as to dart along with the rapidity of an arrow. It is common in all the Arctic seas, and forms an article of commerce, being taken on account of its blubber. They are numerous in the Gulph of St. Lawrence, and go with the tide as high as Quebec. There are fisheries for them and the common porpesse in that river. A considerable quantity of oil is extracted, and of their skin is made a sort of morocco leather, thin, yet strong enough to resist a musket-ball. They are frequent in the Dwina and the Oby, go in small families from five to ten, and advance pretty far up the rivers in pursuit of fish. They are usually caught in nets, but are sometimes harpooned. They bring only one young at a time, which is dusky; but they grow white as they advance in age, the change first commencing on the belly. They are apt to follow boats, as if they were tamed, and appear extremely beautiful by their resplendent whiteness.

DELPHINUS, in astronomy, a constellation of the northern hemisphere, whose stars in Ptolemy's and Tycho's catalogues are ten, and in Mr. Flamsteed's eighteen.

DEMAIN, or DEMESNE, in England signifies the king's lands appertaining to him in property. No common person has any demains simply understood, for they have no land (that of the crown only excepted) which is not holden of a superior, as all depends either mediately, or immediately, on the crown: thus, when a man in pleading would signify his land to be his own, he says that he is or was seized thereof in his demain as of fee; whereby he means, that although his land is to him and his heirs for ever; yet it is not true demain, but depending upon a superior lord, and holden by service, or rent in lieu of service, or by both service and rent.

DEMAND, calling upon a man for any sum or sums of money, or any other thing due. By the several statutes of limitation, debts, claims, &c. are to be demanded and made in time, or they will be lost in law. There are two manners of demands, the one in deed, the other in law: in deed, as in every precipe there is an express demand; in law, as in every entry in land, distress for rent, taking or seizing of goods, and such like acts, which may be done without any words, are demands in law. Where there is a duty which the law makes payable on demand, no demand need be made; but if there is no duty till demand, in such case there must be a demand to make the duty. 1 Lit. 432. Upon a penalty the party need not make a demand; as if a man be bound to pay 20*l.* on such a day, and in default thereof to pay 40*l.* the 40*l.* must be paid without demand. If a person release to another all demands, this is the best release the releasee can have, as he is thereby excluded from all actions, duties, and seizures.

[DEMATIUM, in botany, a genus of the class cryptogamia, order fungi; there are three species. (*b*)

DEMI-CADENCE, in music, a term used in church-music. When the last or final sound of a verse in a chant is on the key-note, it is called a full or complete cadence; but if it fall on any other than the key-note, as the fifth or third, it takes the name of an imperfect or demi-cadence.

DEMI-CULVERIN, a piece of ordnance usually $4\frac{1}{2}$ inches bore, 2700 pound weight, 10 feet long, and carrying point-blank 175 paces.

DEMI-CULVERIN *of the least size*, is $4\frac{1}{4}$ inches bore, 10 feet long, and 2000 pounds weight. It carries a ball of four inches diameter, and of nine pounds weight, and its level range is 174 paces.

DEMI-CULVERIN *of the largest sort*, is $4\frac{3}{4}$ inches bore, $10\frac{3}{4}$ feet long, and weighs 3000 pounds. It carries a ball $4\frac{1}{2}$ inches diameter, weighing 12 pounds 11 ounces, point-blank 178 paces.

DEMI-DITONE, a minor third.

DEMI-GORGE, in fortification, is that part of the polygon which remains after the flank is raised, and goes from the curtin to the angle of the polygon. It is half of the vacant space or entrance into a bastion.

DEMI-LUNE, *half-moon*, in fortification, an outwork consisting of two faces and two little flanks, frequently built before the angle of a bastion, and sometimes also before the curtin, though now much disused.

DEMI-TONE, an interval of half a tone. See SEMI-TONE.

DEMISEMIQUAVER, a note of the ninth degree of length, reckoning from the large, or of the sixth degree of length, reckoning from the semibreve, or longest note now in common use, of which it is a thirty-second part.

DEMISE, is applied to an estate in fee simple, fee tail, or for term of life, and so it is commonly taken in many writs, 2 Inst. 483. The king's death is in law termed the demise of the king to his successor.

DEMONSTRATION, in logic, a series of syllogisms, all the premises of which are either definitions, self-evident truths, or propositions already established.

DEMURRAGE, is an allowance made to the master of a ship by the merchants, for being detained in port longer than the time appointed and agreed for his departure. The rate of this allowance is generally settled in the charterparty. It is now firmly established, that the claim of demurrage ceases as soon as the ship is cleared out, and ready for sailing. Jameson *v.* Lawrie, house of lords, Nov. 10, 1796.

DEMURRER, is a kind of pause or stop, put to the proceedings of an action upon a point of difficulty, which must be determined by the court before any farther proceedings can be had therein. He that demurs in law confesses the facts to be true, as stated by the opposite party; but denies that by the law arising upon those facts, any injury is done to the plaintiff, or that the defendant has made out a lawful excuse. As if the matter of the plaintiff's declaration be insufficient in law, then the defendant demurs to the declaration: if, on the other hand, the defendant's excuse or plea be invalid, the plaintiff demurs in law to the plea; and so on in every other part of the proceedings, where either side perceives any material objection in point of law, upon which he may rest his case. 3 Black. 314. General demurrer being entered, it cannot be afterwards waved, without leave of the court; but a special demurrer generally may, unless the plaintiff has lost a term, or the assizes, by the defendant's demurring. Impey, i. K. B. And upon either a general or special demurrer, the opposite party avers it to be sufficient, which is called a rejoinder in demurrer, and then the parties are at issue in point of law; which issue in law, or demurrer, is argued by counsel on both sides; and if the points are difficult, then it is argued openly by the judges of the court, and if they, or the majority of them, concur in opinion, accordingly judgment is given; but in case of great difficulty, they may adjourn into the exchequer-chamber, where it shall be argued by all the judges. 1 Inst. 71.

Demurrer *to evidence*, is where a question of law arises thereon; and because juries, by direction of the court, usually find a doubtful matter specially, demurrers upon evidence are now seldom used. 5 Rep. 104.

Demurrer *to indictments*. If a criminal joins issue upon a point of law in an indictment or appeal, allowing the fact to be true as laid therein, this is a demurrer in law, by which he insists that the fact as stated is no felony or treason, or whatever the crime is alleged to be. But demurrer to indictments are seldom used, since the same advantages may be taken upon a plea of not guilty; or afterwards in arrest of judgment, where the verdict has established the fact. 4 Black. 333.

DEN, a syllable which added to the names of places shows them to be situated in valleys, or near woods; as Tenterden, in Kent.

DENARIUS, in Roman antiquity, the chief silver-coin among the Romans, worth in our money about sevenpence three farthings. As a weight, it was the seventh part of a Roman ounce.

Denarius *tertius comitatus*, a third part of the profits of county-courts. When these courts had superior jurisdictions, before others were erected, two parts of the profits went to the king, and a third part to the earl of the county.

DENDRITES, or Arborizations. This appellation is given to figures of vegetables which are frequently observed in fossil substances. They are of two kinds; the one superficial, the other internal.

The first are chiefly found on the surface of stones, and between the strata and in the fissures of those of a calcareous nature. Stones of a similar kind, when very compact, sometimes also exhibit internal arborizations; such are the marbles of Hesse, of Angersburg in Prussia, and of Baden-Dourlach on the left bank of the Rhine. Several of these dendrites bear a striking resemblance to the poplar; while others exhibit the straight stem, pyramidal form, and pendant branches, of the fir. Some specimens of dendrites found in Switzerland, represent, in a very surprising manner, plantations of willows; and many of them are so beautiful, as really to appear the work of art.

The superficial dendrites are mostly of a brown, changing gradually to a reddish yellow. The internal dendrites are of a deep black. The most esteemed dendrites are those found in agates; and more particularly in the sardonyx, cornelian, and other precious stones, brought from the East, and which are commonly denominated Moka stones. The Oriental agates display the most varied and beautiful forms. Sometimes they exhibit the appearance of terraces covered with different species of moss, interspersed with plants of the fern-tribe, having large leaves, and the outlines exquisitely finished: the colours are likewise extremely brilliant.

These colours are supposed to be owing to metallic oxides; others are of a different, and perhaps of a bituminous nature. The first are dissolved, and wholly disappear, on immersing the stone in any of the mineral acids; while the others resist their action in a greater or less degree. Some naturalists suppose that dendrites are owing to metallic solutions, or other colouring matters, finding their way through the pores of the stone, and being afterwards forced into the smallest fissures by a mechanism similar to that by which fluids ascend in capillary tubes. But a careful examination of the structure and disposition of dendrites, must evince this opinion to be merely hypothetical; as the principal branches, in diverging from the common stem, observe a great regularity; they are nearly parallel to one another on each side, and always proceed in one direction, like the stems and branches of a real tree; a circumstance inconsistent with the supposition of capillary attraction, which extends equally in all directions.

The same observation is equally applicable to micaceous dendrites, which are frequently found in the granite of the Pyrenees. These dendrites, which greatly

resemble bunches of ostrich feathers, are certainly neither the effect of chance, nor of capillary attraction, but of a principle much more active than that by which simple crystallization is produced.

A species of metallic dendrites is sometimes formed by means of fire. For example, some kinds of copper ore, on being subjected to the action of heat, and afterwards withdrawn from the furnace, appear covered with brilliant yellow spots, some inches in diameter, exactly resembling in form lichens growing on rocks. These arborizations, which are of pure copper, are very singular; being composed of vertical threads, of about a line in height, united in fasciculi, like so many small sheaves standing upright by the side of each other. The finest specimens of this kind of metallic dendrites are produced at a foundry on the Oural mountains. The ore with which this foundry is supplied, is brought from the mines of Touria, where the most beautiful native copper in a state of vegetation yet known, is to be found. In whatever manner we may be inclined to account for this wonderful phenomenon, it should seem, from the above fact, that the same cause which produces these arborizations in the mine, must likewise produce the same effect after the ore has been subjected to the action of fire. See Plate XLII. Nat. Hist. figs. 160 and 161.

DENEB, an Arabic term, signifying tail, used by astronomers to denote several fixed stars. Thus deneb elecet, signifies the bright star in the lion's tail; deneb adigege, that in the swan's tail; &c.

DENDROMETER, from δενδρον, a tree, and μετρεω, I measure, an instrument invented by Messrs. Duncombe and Whittel, for which they obtained a patent, so called from its use in measuring trees. It consists of a semicircle A, plate XLIII. Miscel. fig. 37 and 38, divided into two quadrants, and graduated from the middle; upon the diameter B there hangs a plummet L for fixing the instrument in a vertical position; there are also a chord D parallel to the diameter, and a radius E passing at right angles through the diameter and chord. From a point on the radius hangs an altimeter C, between the chord and diameter, to which are fixed a small semicircle G, and a screw, to confine it in any position. The altimeter, which is contrived to form the same angle with the radius of the instrument as the tree forms with the horizon, is divided from its centre both ways into forty equal parts; and these parts are again divided into halves and quarters. Upon the small semicircle G, on which is accounted the quantity of the angle made by the altimeter and radius, are expressed degrees from 60 to 120, being 30 on each quadrant. The radius is numbered with the same scale of divisions as the altimeter. There is also a nonius to the small semicircle, which shows the quantity of an angle to every five minutes. On the back of the instrument the stock M (fig. 38) of the sliding piece is confined to the axis N, which moves concentrically parallel to the elevation index F on the opposite side, to which it is fixed. This index is numbered by a scale of equal divisions with the altimeter and radius. At the end of the index is a nonius, by which the angles of elevation above, or of depression below, the horizon, measured upon the semicircle of the instrument, are determined to every five minutes. There is also a groove in the radius, that slides across the axis by means of a screw I, working between the chord and semicircle of the instrument; and this screw is turned by the key O. Upon the stock M is a sliding piece P, that always acts at right angles with the altimeter, by means of a groove in the latter. To the shank of the sliding piece is affixed a moveable limb Q, which forms the same angle with the altimeter as the bough forms with the body or trunk of the tree. This limb may be of any convenient length, divided into equal parts of the same scale with all the foregoing divisions. At the extremity of the fixed axis, on a centre, an index R, with telescopic sights, works horizontally upon the moveable limb of the sliding piece. Upon this horizontal index R may be fixed a small quadrant T, described with any convenient radius from the centre on which the index moves, and divided into 90 degrees, beginning at a right line drawn from the centre at right angles with the fiducial edge of the said index; and upon the extremity of the axis is a nonius, whereby to determine the quantity of an angle upon the quadrant every five minutes. There are also two small semicircular arches S, S, serving to keep the sights in a parallel position, each containing an equal number of degrees. Upon these arches is measured the angle subtending a side equal to the difference of the altitudes of the observed objects above the plane of the horizon, and whose base is the nearest distance between the perpendiculars in which these objects are situated. The dendrometer is fitted to a theodolite; and may be used either with or without it, as occasion requires.

The principal use of this instrument is for measuring the length and diameter of any tree, perpendicular or oblique to an horizontal plane, or in any situation of the plane on which it rests, or of any figure, whether regular or irregular, and also the length and diameter of the boughs, by mere inspection; and the inventors of it have calculated tables, annexed to their account of the instrument itself, by the help of which the quantity of timber in a tree is obtained without calculation, or the use of the sliding rule. The instrument is rectified by setting it in a perpendicular position, by means of the plummet, and screwing it to the staff; then the altimeter is placed in the exact position of the tree, whether perpendicular, reclining, or inclining, and screwed fast. If the tree stands on level ground, the horizontal distance from the tree to the axis of the instrument is measured with a tape-line, and the radius is moved with the key till that distance be cut upon it by the inside of the diameter; but if the ground be slanting, the distance from the tree to the instrument is measured, and the elevation index is moved till the point of the tree from which the distance was measured is seen through the sights, and there screwed fast; and the radius is moved backwards or forwards with the key, till this distance is cut upon the elevation index by the perpendicular line of the altimeter; and the horizontal line will be marked upon the radius by the inside of the diameter. In order to obtain the length of the tree, the elevation index is first moved downwards, till the bottom of the tree cut by the horizontal wires is observed through the sights, and the feet and inches marked by the index upon the altimeter below the point of sight or horizontal line are noted down; then the index is moved upwards till the part to which you

would measure, cut by the horizontal wires, is seen, and the feet and inches marked on the altimeter above the point of sight are noted: these two quantities added together give the exact length of the tree, which is inserted in a field-book. For the girth of the tree, the circumference in that part where the horizontal distance was taken, is measured with the tape-line; and a sixth part of this circumference is added to the distance on the radius, which was before cut by the inside of the diameter, because the tape-line, in taking the distance, cannot be applied to the centre of the body of the tree; then the elevation index is lowered to that part of the tree of which the diameter is to be taken, and screwed fast. Set the moveable limb of the sliding piece quite straight, and the edge of the horizontal index upon the first division of it. Turn the whole instrument about to the left hand, till you see through the sights the left side of the tree cut exactly by the perpendicular wires; then, the instrument being fixed, move the sights only upon the sliding piece, till you see the right side of the tree cut also by the perpendicular wires; and you will find the true diameter marked by the horizontal index upon the sliding piece, which is to be entered in a distinct column of the field-book.

For the boughs. Let the distance on the radius be now reduced to its former quantity, and the elevation index moved upwards till the bough is seen through the sights, and screwed fast. Set the moveable part of the sliding piece in a position parallel to the bough, and the edge of the horizontal index on the first division of it. Turn the whole instrument about till you see through the sights the shoot of the bough close to the trunk cut by the perpendicular wires; then move the sights till you see the other end of the bough cut by the said wires, and note the feet and inches marked by the horizontal index on the moveable limb of the sliding piece, which will give the true length of the bough to be inserted in the field-book. And the girth of the bough may be obtained by directing the sight to that part of it whose girth is desired; then by moving the elevation index downwards till you see the under side of the bough cut by the horizontal wires, and there noting the feet and inches marked by the said index on the altimeter; after which, let the elevation index be moved upwards, till the upper side of the bough cut by the horizontal wires is seen; the feet and inches marked upon the altimeter are to be noted as before. The former quantity subtracted from the latter will give the true diameter of the bough, which is entered in the field-book. The true solidity both of the body of the tree and of the boughs may be found from the diameter and lengths in tables calculated for this purpose.

The dendrometer, fitted to a theodolite, may be applied to measuring the heights and distances of objects, accessible or inaccessible, whether situated in planes parallel or oblique to the plane in which the instrument is placed. It may be also used for taking all angles, whether vertical, horizontal, or oblique, in any position of the planes in which they are formed; and thus for facilitating the practical operations of engineering, land-surveying, levelling, mining, &c. and for performing the various cases of plane trigonometry without calculation, of which the inventors have subjoined to their account of this instrument many examples.

DENIER, a small French copper coin, of which 12 make a sol. There were two kinds of deniers, the one tournoise, the other parisis, whereof the latter was worth a fourth part more than the former.

DENIZEN. A denizen is an alien-born, who has obtained letters patent whereby he is constituted an English subject. A denizen is in a middle state, between an alien and a natural-born or naturalized subject, partaking of the nature of both. He may take lands by purchase; or derive a title by descent through his parents or any ancestor, though they be aliens. By stat. 25 Geo. II. c. 39, no natural-born subject shall derive a title through an alien parent or ancestor, unless he be born at the time of the death of the ancestor, who dies seized of the estate which he claims by descent; with this exception, that if a descent shall be cast upon a daughter of an alien, it shall be divested in favour of an after-born son, and in case of an after-born daughter or daughter only, all the sisters shall be coparceners. The children born previous to the denization of their parent cannot inherit by descent, whilst those of a foreigner naturalized are in every respect entitled to the same privileges as British subjects. See ALIEN.

DENOMINATOR, in arithmetic, a term used in speaking of fractions. The denominator of a fraction is the number below the line, showing into how many parts the integer is supposed to be divided. Thus in the fraction $\frac{3}{4}$, the number 4 shows that the integer is divided into four parts. So in the fraction $\frac{a}{b}$, b is the denominator.

DENSITY *of bodies*, is that property directly opposite to rarity, whereby they contain such a quantity of matter under such a bulk. Accordingly, a body is said to have double or triple the density of another body, when their bulk being equal, the quantity of matter in the one is double or triple the quantity of the matter in the other. See GRAVITY.

DENSITY *of the planets*. In homogeneous, unequal, spherical bodies, the gravities on their surfaces are as their diameters when the densities are equal, or the gravities are as the densities when the bulks are equal; therefore, in spheres of unequal magnitude and density, the gravity is in the compound ratio of the diameters and densities, or the densities are as the gravities divided by the diameters. Knowing therefore the diameters of the planets by observation and comparison, and the gravities at their surface by means of the revolution of the satellites, the relation of their densities becomes known. And as the mean density of the earth is found to be about $4\frac{1}{2}$ times that of water (Philos. Trans. 1778), hence the densities of the planets, with respect to water become known, and are as follow.

	Densities.
Water	1
The Sun	$1\frac{2}{13}$
Mercury	$9\frac{1}{6}$
Venus	$5\frac{11}{15}$
The Earth	$4\frac{1}{2}$
Mars	$3\frac{2}{7}$
The Moon	$3\frac{1}{11}$
Jupiter	$1\frac{1}{4}$
Saturn	$0\frac{13}{32}$
Herschel	$0\frac{29}{100}$

As it is not likely that any of these bodies are homogeneal, the densities here determined are supposed to be the mean densities.

DENTALIUM, in natural history, a genus of the vermes testacea order. The shell has no hinge, and is formed only of one piece. The figure approaches to cylindric or conic; and is sometimes crooked, sometimes straight, sometimes close at one end, sometime open at both; its inhabitant is called nereis. There are eight species. The name dentalium has been given this shell, from the great resemblance it has to the dentes canini of quadrupeds. Several species of it frequent the shores of Italy, Portugal, &c. In England they are found fossil in clay-pits, some smooth, some striated, but in much greater abundance in the mountains of France and Italy.

DENTARIA, *toothwort* or *tooth-violet*, a genus of the siliquosa order, in the tetradynamia class of plants, and in the natural method ranking under the 39th order, siliquosæ. The siliqua parts with a spring, and the valvules roll spirally backwards; the stigma is emarginated, the calyx closing longitudinally. There are four species, hardy perennials; producing annual stalks 12 or 18 inches high, adorned with many-lobed leaves, and spikes of quadrupetalous cruciform flowers of a red or purple colour. They delight in shady places, and are propagated either by seeds or parting the roots.

DENTELIA, a genus of the monogynia order, in the pentandria class of plants. The calyx is a five-parted perianthium, with small subulated leaves; the stamina five short subulated filaments; the antheræ small; the pericarpium a globular bilocular capsule; the seeds egg-shaped, and very numerous. There is one species, a native of New Caledonia.

DENTILES, or DENTILS. See ARCHITECTURE.

DENTITION, the breeding, or cutting, the teeth in children. Among all the disorders which afflict children, there are none that generates such grievous symptoms as difficult dentition. About five or six months after birth, the teeth generally begin to make their appearance: first, the incisores, or fore-teeth; next, the canini, or dog-teeth; and lastly, the molares, or grinders. About the seventh year there come a new set; and at twenty-one the two inner grinders, called dentes sapientæ, or teeth of wisdom. See ANATOMY, and MEDICINE.

DENUNCIATION, a solemn publication or promulgation of any thing. All vessels of enemies are lawful prize, after denunciation or proclamation of war. The design of the denunciation of excommunicated persons is, that the sentence may be the more fully executed by the person's being more known.

DEODAND, is where any moveable thing inanimate, or beast animate, moves or causes the death of any reasonable creature, by mischance, without the will or fault of himself, or of any person. 3 Inst. 57. Formerly wherever the thing which was the occasion of a man's death was in motion at the time, not only that part thereof which immediately wounded him, but all things which moved together with it, and helped to make the wound more dangerous, were forfeited also. 1 Haw. 66. But juries have lately determined very differently. As these forfeitures seem to have been originally founded in the superstition of an age of ignorance, they are now discountenanced in Westminster-hall. Fost. 266.

DE ONERANDA PRO RATA PORTIONIS, is a writ that lies where one is distrained for a rent, that ought to be paid by others proportionably with him.

DEPARTURE from a plea or matter, is where a man pleads a plea in bar of an action, which being replied to, he in his rejoinder shows another matter contrary to this first plea: this is called a departure from his bar. It may also be applied to a plaintiff, who in his replication shows new matter from his declaration. Plow. Com. 7, 8. Co. 2. par. fo. 147.

DEPARTURE, in navigation, is the easting or westing of a ship in respect of the meridian it departed or sailed from; or it is the difference of longitude, either east or west, between the present meridian the ship is under, and that where the last reckoning or observation was made. This departure, any where but under the equator, must be counted according to the number of miles in a degree proper to the parallel the ship is under. The departure, in plane and Mercator's sailing, is always represented by the base of a right-angled plane triangle, where the course is the angle opposite to it, and the distance sailed is the hypothenuse; the perpendicular or other leg being the difference of latitude. And then the theorem for finding it, is always this: as radius, is to the sine of the course, so is the distance sailed, to the departure sought.

DEPORTATION, a sort of banishment used by the Romans, whereby some island or other place was allotted to a criminal for the place of his abode, with a prohibition not to stir out of the same on pain of death.

DEPOSIT, among civilians, something that is committed to the custody of a person, to be kept without any reward, and to be returned again on demand. Deposit is distinguished into simple and judiciary.

DEPOSITION. Proof in the high court of chancery is by the depositions of witnesses; and the copies of such, regularly taken and published, are read as evidence at the hearing. For the purpose of examining witnesses in or near London, there is an examiner's office appointed; but for such as live in the country, a commission to examine witnesses is usually granted to four commissioners, two named on each side, or any three or two of them, to take the depositions there. And if the witnesses reside beyond sea, a commission may be had to examine them there, upon their own oaths; and if foreigners, upon the oaths of two skilful interpreters. The commissioners are sworn to take the examinations truly, and without partiality, and not to divulge them till published in the court of chancery; and their clerks are also sworn to secresy. The witness are compellable by process of subpœna, as in the courts of common law, to appear and submit to examination; and when their depositions are taken, they are transmitted to the court with the same care that the answer of a defendant is sent. 3 Black. 445.

DEPOT, any particular place in which military stores are deposited for the use of an army. In a more extensive sense, it means several magazines collected together for that purpose. It also signifies an appropriated fort, or place, for the reception of recruits, or detached parties, belonging to different regiments. The barracks near Maid stone are depots for the British cavalry, and Chatham is allotted to the infantry. During hostilities, the greatest attention should be given to preserve the seve-

ral depots which belong to the fighting army. Hence the line of operation should be invariable connected with them; or rather no advance should be made upon that line, without the strictest regard being paid to the one of communication.

DEPOT is also used to denote a particular place at the tail of the trenches, out of the reach of the cannon of the place; where the troops generally assemble who are ordered to attack the outworks, or support the troops in the trenches, when there is reason to imagine the besieged intend making a vigorous sally.

DEPOT likewise means a temporary magazine for forage, for fascines, gabions, tools, and every other thing necessary for the support of an army, or for carrying on a siege.

DEPRESSION *of the pole*. When a person sails or travels towards the equator, he is said to depress the pole; because as many degrees as he approaches nearer the equator, so many degrees will the pole be nearer the horizon. This phenomenon arises from the spherical figure of the earth. When a star is under the horizon, it is termed the depression of that star under the horizon. The altitude or depression of any star is an arch of the vertical intercepted between the horizon and that star.

DEPRESSION *of the visible horizon*, or *dip of the horizon*, denotes its sinking or dipping below the true horizontal plane, by the observer's eye being raised above the surface of the sea; in consequence of which the observed altitude of an object is by so much too great.

Thus, the eye being at E, the height AE above the surface of the earth, whose centre is C, then EH is the real horizon, and E*h* the visible one, below the former by the angle HE*h*, by reason of the elevation AE of the eye.

To compute the depression or dip of the horizon.—In the right-angled triangle CE*h* (Pl. XLIII. Miscel. fig. 39), are given C*h*, the earth's radius = 21000000 feet, and the hypothenuse CE = the radius increased by the height AE of the eye; to find the angle C, which is = the angle HE*h*, or depression sought;

As C*h* : CE : : radius : sec. ∠C,

or As CE : C*h* : : radius : cosin. ∠C.

By either of these theorems are computed the numbers in the following table; which shows the depression or dip of the horizon of the sea for different heights of the eye, from 1 foot to 100 feet.

Height of the eye.	Dip of the horizon.	Height of the eye.	Dip of the horizon.	Height of the eye.	Dip of the horizon.
Feet.	′ ″	Feet.	′ ″	Feet.	′ ″
1	0 57	13	3 26	26	4 52

12	3 18	24	4 40	100	9 33

DEPRESSOR. See ANATOMY.

DEPRIVATION, in the canon law, is an ecclesiastical censure, by which a clergyman is deprived of his personage, vicarage, or other spiritual promotion of dignity. Degg's Parson's Councellor, c. 9.

Causes of deprivation. If a clerk obtains preferment in the church by simonical contract; if he is an excommunicate, a drunkard, fornicator, adulterer, infidel, or heretic; or guilty of murder, manslaughter, perjury, forgery, &c.; if a clerk is illiterate, and not able to perform the duty of his church; if he is a scandalous person in life and conversation, or bastardy is objected against him: if he is under age, viz. the age of twenty-three years; is disobedient and incorrigible to his ordinary, or a nonconformist to the canons; if he refuses to use the common-prayer, or preaches in derogation of it; does not administer the sacrament, or read the articles of religion, &c.; if any parson, vicar, &c. has one benefice with cure of souls, and takes plurality without a faculty or dispensation; or if he commits waste in the houses and lands of the church, called dilapidations: all these have been held good causes for deprivation of priests. Deg. Par. Coun. 98, 99.

DEPTH, in geometry, the same with altitude; though, strictly speaking, we only use the term depth to denote how much one body, or part of a body, is below another. See HEIGHT, &c.

DEPTH *of a battalion, squadron, &c.* the number of men in a file, or who stand before each other in a straight line. In the ancient armies this was very great.

DEPUTY, is one that exercises an office in another's right; and the forfeiture or misdemeanour of such deputy shall cause the person, whom he represents, to lose his office.

There is a great difference between a deputy and assignee of an office; for an assignee has an interest in the office itself, and does all things in his own name, for which his grantor shall not answer unless in special cases; but a deputy has not any interest in the office, but is only the shadow of an officer, in whose name he does all things. 9 Rep. 49.

A superior officer must answer for his deputy in civil actions if he is not sufficient; but in criminal cases it is otherwise, where deputies are to answer for themselves. 2 Inst. 191.

DERMESTES, in zoology, a genus of insects belonging to the order of coleoptera. The antennæ are clavated, with three of the joints thicker than the rest; the breast is convex; and the head is inflected below the breast. There are thirty species, of which the following deserve notice:

1. The lardarius is of an oblong form, and of a dim-black colour, easily distinguishable by a light-brown stripe, that occupies transversely almost the anterior half of the elytra. That colour depends on small grey hairs situated on that part. The stripe is irregular at its edges; and is intersected through the middle by a small transversed streak of black spots, three in number on each of the elytra, the middlemost of which is somewhat lower than the rest, which gives the black streak a serpentine form. Its larva, that is oblong, somewhat hairy, and divided into segments alternately dark and light-coloured, gnaws and destroys preparations of animals pre-

served in collections, and even feeds upon the insects. See Plate XLII. Nat. Hist. fig. 162.

2. The domesticus varies greatly in size and colour; some being found of a dark-brown, others of a much lighter hue. The form of it is oblong, almost cylindrical. The elytra are striated; the thorax is thick, and rather gibbous. This little animal, when touched, draws in its head under its thorax, and its feet beneath its abdomen; remaining so motionless, that one would suppose it dead. This is the same insect which makes in wooden furniture those little round holes that reduce it to powder.

3. The violaceus is a beautiful little insect; its elytra are of a deep violet-blue. The thorax is covered with greenish hairs; the legs are black. The whole animal being of a glittering brilliancy renders it a pleasing object. The larva, as well as the perfect insect, inhabits the bodies of dead animals.

4. The fumatus is of a light-brown colour, except the eyes, which are black. It is, however, sometimes more or less deep. The thorax is marginated, and the insect has the whole carriage of a scarabæus; but its antennæ have the character of those of the dermestæ. This little creature is found in dung. It also frequently finds its way into houses.

5. The ferrugineus is the largest of the genus; its colour is a rusty iron, having many oblong, velvety, black spots upon the elytra, which give the insect a gloomy, yet elegant, appearance. The antennæ differ from the preceding species, the last three articulations being considerably longer, thicker, and not perfoliated.

The twenty-five other species are distinguished by their colour. Many varieties of this genus, as well as the larvæ, are to be met with in dried skins, bark of trees, wood, carcases of dead animals, &c.

DERVIS, a name given to all Mahommedan monks, though of various orders. The most noted among them are the bektashi, the mevelevi, the kadri, and the seyah. The bektashi, who are allowed to marry and live in cities and towns, are obliged, by the rules of their order, to visit remote lands, and to salute every one they meet with gazel, or love-songs; and with esma, or the invocation of the names of God, and humbly to wish him prosperity, which they do by repeating the word civallah, a solemn exclamation of the wrestlers, by which the conquered yields the palm to the conqueror. The mevelevi, so called from Mevelava their founder, are used to turn round for two or three hours together with such swiftness, that you cannot see their faces; they are great lovers of music: in their monasteries they profess great humility and poverty, and when visited make no distinction of persons; they first bring their guests coffee to drink; and, if the ways have been dirty, they wash their feet and sandals. The kadri, with a peculiar superstition, emaciate their bodies; they go quite naked, except their thighs, and often join hands and dance, sometimes a whole day, repeating, with great vehemence, "Hu! hu! hu!" (one of the names of God) till, like mad men, they fall on the ground, foaming at the mouth, and running down with sweat: the prime vizir Kuprili Achmed Pasha, thinking this sect unbecoming the Mahommedan religion, ordered it to be suppressed; but, after his death, it revived, and is at present more numerous than ever, especially at Constantinople. The seyah are wanderers, and though they have monasteries, yet they often spend their whole life in travelling; when they are sent out, their superiors impose upon them such a quantity of money or provisions, forbidding them to come back till they have procured it, and sent it to the monastery; wherefore when a seyah comes into a town, he cries aloud in the market-place, "Ya allah senden," &c. "O God! give me, I pray, five thousand crowns, or a thousand measures of rice." Many of these dervises travel over the whole Mahommedan world, entertaining the people wherever they come with agreeable relations of all the curiosities they have met with. There are dervises in Egypt, who lives with their families, and exercise their trades, of which kind are the dancing dervises at Damascus. They are all distinguished among themselves by the different forms and colours of their habits; those of Persia wear blue; the solitaries and wanderers wear only rags of different colours; others carry on their heads a plume made of the feathers of a cock; and those of Egypt wear an octagonal badge of a greenish-white alabaster at their girdles, and a high stiff cap, without any thing round it.

DESCANT, in the old music, the art of composing in several parts. Descant is threefold, viz. plain, figurative, and double.

DESCENSION, in astronomy, is either right or oblique. Right descension is an arch of the equinoctial, intercepted between the next equinoctial point and the intersection of the meridian, passing through the centre of the object, at its setting, in a right sphere. Oblique descension is an arch of the equinoctial intercepted between the next equinoctial point and the horizon, passing through the centre of the object, at its setting, in an oblique sphere.

DESCENT, in general, is the tendency of a body from a higher to a lower place. Heavy bodies, meeting with no resistance, descend with an uniformly accelerated motion, for the laws of which see MECHANICS.

Laws of descent of bodies. 1st. Heavy bodies, in an unresisting medium, fall with an uniformly accelerated motion. For it is the nature of all constant and uniform forces, such as that of gravity, at the same distance from the centre of the earth, to generate or produce equal additions of velocity in equal times. So that if in one second of time there is produced one degree of velocity, in two seconds there will be two degrees of velocity, in three seconds three degrees, and so on; the degree or quantity of velocity being always proportional to the length of the time.

2d. The space descended by an uniform gravity, in any time, is just the half of the space that might be uniformly described in the same time by the last velocity acquired at the end of that time, if uniformly continued. For as the velocity increases uniformly in an arithmetical progression, the whole space descended by the variable velocity will be equal to the space that would be described with the middle velocity uniformly continued for the same time; and this again will be only the space that would be with the half of the last velocity, also uniformly continued for the same time, because the last velocity is double of the middle velocity, being produced in a double time.

3d. The spaces descended by an uniform gravity, in

different times, are proportional to the squares of the times, or to the squares of the velocities. For the whole space descended in any number of particles of time, consists of the sums of all the particular spaces or velocities, which are in arithmetical progression; but the sum of such an arithmetical progression, beginning at 0, and having the last term and the number of terms the same in quantity, is equal to half the square of the last term, or of the number of terms; therefore the whole sums are as the squares of the times, or of the velocities.

This theory of the descents by gravity was first discovered and taught by Galileo, who afterwards confirmed the same by experiments; which have often been repeated in various ways by many other persons since his time, as Grimaldi, Riccioli, Huygens, Newton, and others, all confirming the same laws.

The experiments of Grimaldi and Riccioli were made by dropping a number of balls, of half a pound weight, from the top of several towers, and measuring the times of falling by a pendulum. An abstract of their experiments is exhibited here below:

Vibrations of the pendulum.	The time.		Space at the end of the time.	Space descended each time.

12	2	0	60	45
18	3	0	135	75
24	4	0	240	105

The space descended by a heavy body in any given time, being determined by experiment, is sufficient, in connection with the preceding theorems, for determining every inquiry concerning the times, velocities, and spaces descended, depending on an uniform force of gravity. From many accurate experiments made in England, it has been found that a heavy body descends freely through 16 feet 1 inch, or $16\frac{1}{12}$ feet; in the first second of time; and consequently, by theorem 2, the velocity gained at the end of 1 second, is $32\frac{1}{6}$ feet per second. Hence, by the same, and theorem 3, the velocity gained in any other time t is $32\frac{1}{6}t$, and the space descended is $16\frac{1}{12}t^2$. So that, if v denotes the velocity, and s the space due to the time t, and there be put $g = 16\frac{1}{12}$; then is

$$v = 2gt = 2\sqrt{gs} = \frac{2s}{t}.$$

$$s = gt^2 = \frac{v^2}{4g} = \tfrac{1}{2}tv.$$

$$t = \frac{v}{2g} = \sqrt{\frac{s}{g}} = \frac{2s}{v}.$$

The experiments with pendulums give also the same space for the descent of a heavy body in a second of time. Thus, in the latitude of London, it is found by experiment, that the length of a pendulum vibrating seconds, is just $39\frac{1}{8}$ inches; and it being known that the circumference of a circle is to its diameter, as the time of one vibration of any pendulum is to the time in which a heavy body will fall through half the length of the pendulum; therefore, as $3.1416 : 1 :: 1 : \frac{1}{3.1416}$, which is the time of descending through $19\frac{9}{16}$ inches, or half the length of the pendulum; then, spaces being as the squares of the times, as $\frac{1}{3.1416^2} : 1^2 :: 19\frac{9}{16} : 193$ inches, or 16 feet 1 inch, which therefore is the space a heavy body will descend through in one second; the very same as before.

4th, For any other constant force, instead of the perpendicular free descent by gravity, find by experiment, or otherwise, the space descended in one second by that force, and substitute that instead of $16\frac{1}{12}$ for the value of g in these formulæ: or, if the proportion of the force to the force of gravity be known, let the value of g be altered in the same proportion, and the same formulæ will still hold good. So, if the descent be on an inclined plane, making, for instance, an angle of 30° with the horizon; then, the force of descent upon the plane being always as the sine of the angle it makes with the horizon, in the present case it will be as the sine of 30°, that is, as $\frac{1}{2}$ the radius; therefore, in this case, the value of g will be but half the former, $8\frac{1}{24}$, in all the foregoing formulæ.

Or, if one body descending perpendicularly draw another after it, by means of a cord sliding over a pulley; then it will be, as the sum of the two bodies is to the descending body, so is $16\frac{1}{12}$ to the value of g in this case; which value of it being used in the said formulæ, they will still hold good. And in like manner for any other constant forces whatever.

5th, The time of the oblique descent down any chord of a circle, drawn either from the uppermost or lowermost point of the circle, is equal to the perpendicular descent through the diameter of the circle.

6th, The descent, or vibration, through all arcs of the same cycloid, are equal, whether great or small.

7th, But the descent, or vibration, through unequal arcs of a circle, are unequal; the times being greater in the greater arcs, and less in the less.

Descent, *line of swiftest*, is that which a body, falling by the action of gravity, describes in the shortest time possible, from one given point to another. And this line, it is proved by philosophers, is the arc of a cycloid, when the one point is not perpendicularly over the other. See **Cycloid**.

Descent, in law, or hereditary succession, is the title by which a man on the death of his ancestor acquires his estate by right of representation as his heir at law; and an estate so descending to the heir is in law called inheritance. 2 Black. 201.

Descent is of three kinds; by common law, by custom, or by statute. By common law, as where one has land of inheritance in fee-simple, and dies without disposing of it in his life-time, and the land goes to the eldest son and heir of course, being cast upon him by the law. Descent of fee-simple by custom, is sometimes to all the sons or to all the brothers (where one brother dies without issue), as in gavelkind; sometimes to the youngest son, as borough-English; and sometimes to the eldest daughter, or the youngest, according to the customs of particular places. Descent by statute is of fee-tail, as directed by the statute of Westminster 2, de donis.

Descent at common law is either lineal or collateral. Lineal consanguinity is that which subsists between persons, of whom one is descended in a direct line from the other, as between a man and his father, grandfather, and great-grandfather, and so upwards in a direct ascending line; or between a man and his son, grandson, great-grandson, and so downwards in the direct descending line. Every generation, in this lineal direct consanguinity, constitutes a different degree, reckoned either upwards or downwards; the father is related in the first degree, and so likewise are the son, grandsire, and grandson, in the second; great-grandsire, and great-grandson, in the third. This is the only natural way of reckoning the degrees in the direct line, and therefore universally obtains, as well in the civil and canon as in common law. Collateral kindred answers to the same description; collateral relations agreeing with the lineal in this, that they descend from the same stock or ancestor; but differing in this, that they do not descend one from the other. Collateral kinsmen are therefore such as lineally spring from one and the same ancestor, who is the stirps or root, stipes, trunk or common stock, whence these relations are branched out. As if a man has two sons, who have each a different issue, both these issues are lineally descended from him as their common ancestor: and they are collateral kinsmen to each other, because they are all descended from this common ancestor; and all have a portion of his blood in their veins, which denominates them consanguineors. Inheritances shall lineally descend to the issue of the person last actually seized, in infinitum, but shall never lineally ascend. 3 Black. 208.

The male issue shall be admitted before the female; and where there are two or more males in equal degree, the eldest only shall inherit (except where there are particular local customs to the contrary); but the females shall inherit all together, except in case of succession to the crown, which is indivisible; and of succession to dignities and titles of honour: yet where a man holds an earldom to him and the heirs of his body, and dies, his eldest daughter shall not succeed of course to the title of countess, but the dignity is in suspense or abeyance till the king shall declare which of the daughters shall have that title. 2 Black. 216.

Descent of crown lands. All the lands whereof the king is seized in jure coronæ, shall attend upon and follow the crown: so that to whomsoever the crown descends, those lands and possessions descend also. Plowd. 247.

Descent of dignities. The dignity of peerage is personal, annexed to the blood, and so inseparable, that it cannot be transferred to any person, or surrendered even to the crown: it can move neither backward nor forward, but only downward to posterity; and nothing but corruption of blood, as if the ancestor be attainted of treason or felony, can hinder the descent to the right heir. Lex Const. 85.

Descent, in heraldry, is used to express the coming down of any thing from above; as, a lion en descent, is a lion with his head towards the base point and his heels towards one of the corners of the chief, as if he were leaping down from some high place.

Descents, in fortification, are the holes, vaults, and hollow places, made by undermining the ground. The descent into the moat or ditch is a deep passage made through the esplanade and covert-way, in form of a trench, whereof the upper part is covered with madriers and clays, to secure the besiegers from the enemy's fire. In wet ditches this trench is on a level with the surface of the water, but in dry ones it is sunk as deep as the bottom of the ditch.

DESCRIPTION, in law. In deeds and grants there must be a certain description of the lands granted, the places where they lie, and the person to whom granted, &c. to make them good. But wills are more favoured than grants as to those descriptions; and a wrong description of the person will not make a devise void, if there be otherwise a sufficient certainty what person was intended by the testator. 1 Nels. Abr. 467.

Where a first description of land, &c. is false, though the second be true, a deed will be void: contra, if the first be true, and the second false. 3 Rep. 2, 3, 8, and 10.

DESERTER, in a military sense, a soldier who, by running away from his regiment or company, abandons the service.

A deserter is, by the articles of war, punishable by death, and, after conviction, is hanged at the head of the regiment he formerly belonged to, with his crime written on his breast, and suffered to hang till the army leave that camp, for a terror to others.

DESACHE', in heraldry, is where a beast has its limbs separated from its body, so that they still remain on the escutcheon, with only a small separation from their natural places.

DESIGN, in a general sense, the plan, order, representation or construction of a building, book, painting, &c.

In building the term ichnography may be used, when by design is only meant the plan of a building, or a flat figure drawn on paper: when some side or face of the building is raised from the ground, we may use the term orthography; and when both front and sides are seen, in perspective, we may call it scenography.

Design, in manufactories, expresses the figures with which the workman enriches his stuff, or silk, and which he copies after some painter, or eminent draughtsman, as in diaper, damask, flowered silk, tapestry, and the like.

In undertaking of such kinds of figured stuffs, it is necessary, says M. Savary, that before the first stroke of the shuttle, the whole design be represented on the threads of the warp; we do not mean in colours, but with an infinite number of little packthreads, which, being disposed so as to raise the threads of the warp, let the workmen see, from time to time, what kind of silk is to be put in the eye of the shuttle, for woof. This method of preparing the work is called reading the design and reading the figure, which is performed in the following manner: A paper is provided, considerably broader than the stuff, and of a length proportionate to what is intended to be represented on it. This they divide lengthwise by as many black lines as there are intended threads in the warp; and cross these lines, by others drawn breadthwise, which, with the former, make little equal squares; on the paper thus squared, the draughtsman designs his figures, and heightens them with colours as he sees fit. When the design is finished, a workman reads it, while another lays it on the simblot.

To read the design, is to tell the person who manages the loom, the number of squares, or threads, comprised in any space, intimating at the same time whether it is ground or figure. To put what is read on the simblot, is to fasten little strings to the several packthreads, which are to raise the threads, named; and thus they continue to do till the whole design is read. Every piece being composed of several repetitions of the same design, when the whole design is drawn, the drawer, to begin the design afresh, has nothing to do but raise the little strings, with slip-knots, to the top of the simblot, which he had let down to the bottom: this he is to repeat as often as is necessary till the whole is manufactured. The ribbon-weavers have likewise a design, but far more simple than that now described. It is drawn on paper, with lines and squares representing the threads of the warp and woof. But instead of lines of which the figures of the former consist, these are constituted of points only, or dots, placed in certain of the little squares, formed by the intersection of the lines. These points mark the threads of the warp that are to be raised and the spaces left blank denote the threads that are to keep their situation: the rest is managed as in the former.

DESIGN is also used, in painting, for the first idea of a large work, drawn roughly, and in little, with an intention to be executed and finished in large. The art of painting has been by some of the greatest masters divided into the design or draught, the proportion, the expression, the claro-obscuro, the ordonnance, the colouring, and the perspective.

Design, in painting, is the simple contour or outlines of the figures intended to be represented, or the lines that terminate and circumscribe them: such design is sometimes drawn in crayons, or ink without any shadows at all. Sometimes it is etched; that is, the shadows are expressed by sensible outlines, usually drawn across each other with the pen, crayon, or graver. Sometimes, again, the shadows are done with the crayon rubbed so as that there do not appear any lines: at other times, the grains or strokes of the crayon appear, as not being rubbed: sometimes the design is washed, that is, the shadows are done with a pencil in Indian ink, or some other liquor; and sometimes the design is coloured, that is, colours are laid on much like those intended for the grand work.

The essential requisites of a design are correctness, good taste, elegance, character, diversity, expression, and perspective. Correctness depends on the justness of the proportions, and knowledge of anatomy. Taste is a certain manner of correctness peculiar to the artist, derived either from nature, masters, or studies, or all of them united. Elegance gives a delicacy that not only strikes persons of judgment, but communicates an agreeableness that pleases universally. The character is what is peculiar to each thing, in which there must be diversity, insomuch that every thing has its peculiar character to distinguish it. The expression is the representation of an object, according to the circumstances it is supposed to be in. Perspective is the representation of the parts of a painting, or a figure, according to the situation they are in with regard to the point of sight.

The design or draught, is a part of the greatest import and extent in painting. It is acquired chiefly by genius and application, rules being of less avail here than in any other branches of the art, as colouring, &c. The principal rules that regard design are, that novices accustom themselves to copy good originals at first sight; not to use squares in drawing, lest they stint and confine their judgment; to design well from life, before they practise perspective; to learn to adjust the size of their figures to the visual angle, and the distance of the eye from the model or object; to mark out all the parts of their design before they begin to shade; to make their contours in great pieces, without taking notice of the little muscles, and other breaks; to make themselves masters of the rules of perspective; to observe the perpendicular, parallel, and distance, of every stroke; to compare and oppose the parts that meet and traverse the perpendicular, so as to form a kind of square in the mind, which is the great and almost the only rule of designing justly; to have regard not only to the model, but to the parts already designed, there being no such thing as designing with strict justness, but by comparing and proportioning every part to the first. All the other rules relate to perspective. See PAINTING, and PERSPECTIVE.

DESON TORT DEMESN, in law, a formula used in action of trespass, by way of reply to the defendant's plea; signifying that the trespass was his own voluntary and free act.

DETACHED PIECES, in fortification, are such outworks as are detached or at a distance from the body of the place; as demilunes, ravelins, bastions, &c. In painting the figures are said to be well detached, when they stand free and disengaged from each other.

DETACHMENT, in military affairs, a certain number of soldiers drawn out from several regiments or companies equally, to be employed as the general thinks proper; whether on an attack, at a siege, or in parties to scour the country. A detachment of two or three thousand men, is a command for a brigadier; eight hundred, for a colonel; four or five hundred, for a lieutenant-colonel. A captain never marches on a detachment with less than fifty men, a lieutenant, an ensign, and two serjeants. A lieutenant is allowed thirty, and a serjeant; and a serjeant ten or twelve men. Detachments are sometimes made of entire squadrons and battalions.

DETENTS, in clock-work, are those stops, which by being lifted up or let down, lock or unlock the clock in striking. See CLOCK-WORK.

DETENT-WHEEL, or *hoop-wheel*, in a clock, that wheel which has a hoop almost round it, in which there is a vacancy at which the clock locks.

DETERGENTS, in pharmacy, such medicines as are not only softening and adhesive, but also, by a peculiar activity, conjoined with a suitable configuration of parts, are apt to abrade, and carry along with them, such particles as they lay hold on in their passage. See PHARMACY.

DETERMINATE PROBLEM, in geometry, that which has but one, or at least, a limited number of answers.

DETINUE is a writ which lies where any man comes to goods or chattels either by delivery or by finding, and refuses to re-deliver them; and it lies for the detaining, when the detaining was unlawful. 1 Inst. 286.

In this writ the plaintiff shall recover the thing detained; and therefore it must be so certain, as that it may be specifically known. Therefore it cannot be brought for money, corn, or the like, for that cannot be known from other money or corn, unless it is in a bag or sack, for then it may be distinguishably marked. Ibid.

But detinue may be brought for a piece of gold of the price of 21*s.* though not for 21*s.* in money; for there is a demand of a particular piece. Buller, N. P. 30.

In order therefore to ground an action of detinue, which is only for the detaining, these points are necessary: 1. That the defendant came lawfully by the goods, as either by delivery to him, or finding them. 2. That the plaintiff has a property. 3. That the goods themselves are of value. And 4. that they be ascertained in point of identity. Upon this, the jury, if they find for the plaintiff, assess the respective values of the several parcels detained, and also damages for the detention; and the judgment is conditional, that the plaintiff recover the said goods, or (if they cannot be had) their respective values, and also the damages for detaining them. Ib.

DETINUE OF CHARTERS. An action of detinue lies for charters which make the title of lands; and the heir may have detinue of charters, although he have not the land. But if they concern the freehold, the action must be in the common-pleas, and no other court.

DETONATION, in chemistry, the noise and explosion which any substance makes upon the application of fire to it. It is also called fulmination; such are the explosions of gunpowder, of fulminating silver, gold, &c.

DETRANCHE', in heraldry, a line bendwise, proceeding always from the dexter side but not from the very angle, diagonally athwart the shield.

DEVASTAVIT, or *devastarunt bona testatoris*, in law, is a writ which lies against executors, for paying debts for simple contract, before debts or bonds, and specialities, or the like; for in this place the executors are as liable to action, as if they had wasted the goods of the testator riotously, or converted them to their own use; and are compellable to pay such debts by speciality out of their own goods, to the value of what they so paid illegally. Cowel.

By the 30 C. II. c. 7. if an executor de son tort waste the goods and die, his executors shall be liable in the same manner as their testator would have been, if he had been living. And it has since been adjudged, that a rightful executor, who wastes the goods of the testator, is in effect an executor de son tort, for abusing his trust. 5 Mod. 113. And his executor or administrator is made liable to a devastavit by 4 and 5 W. and M. c. 24.

DEVENERUNT, in law, a writ directed to the escheator, when any tenant of the king holding in capite, died: and when his son and heir, within age, and in the king's custody, died; then this writ issued, commanding the eschentor, that he, by the oath of good and lawful men, inquire what lands and tenements, by the death of the tenant, came to the king. Dyer, 360. pl. 4.

DEVESTING, in old law-books, the reverse of investing or investiture. See the article INVESTITURE.

DEVISE, or *device*, in heraldry, painting, and sculpture, any emblem used to represent a certain family, person, action, or quality; with a suitable motto, applied in a figurative sense.

DEVISE, in law, the act whereby a person bequeaths his lands or tenements to another, by his last will and testament. The person who makes this act, is called the devisor, and he in whose favour the act is made, is termed in law the devisee.

DEVOTION, *devotio*, a sincere and ardent worship of the deity.

DEVOURING, in heraldry, is when fishes are borne in an escutcheon in a feeding posture, for they swallow all the meat whole.

DEW, a dense moist vapour, falling on the earth in form of a misling rain. See METEOROLOGY.

DEXTANS, in Roman antiquity, ten ounces, or $\frac{10}{12}$ of their libra.

DEXTER, in heraldry, an appellation given to whatever belongs to the right side of the shield, or coat of arms: thus we say, bend-dexter, dexter point, &c.

DIABETES, in physic, an excesssive discharge of urine, which comes away crude, and exceeds the quantity of liquids drunk. See MEDICINE.

DIACAUSTIC CURVE, a species of the caustic curves formed by refraction. Thus if you imagine an infinite number of rays BA, BM, BD, &c. (Pl. XLIII. Miscel. fig. 40) issuing from the same luminous point B to be refracted to or from the perpendicular MC by the given curve AMD, and so that CE, the sines of the angles of incidence CME, be always to CG, the sines of the refracted angles CMG, in a given ratio; then the curve HFN, which touches all the refracted rays, is called the diacaustic, or caustic refraction. See CAUSTIC CURVE.

DIACHYLON, in pharmacy, an emollient digestive plaster. See PHARMACY.

DIADELPHIA, in the Linnæan system of botany, a class of plants, the seventeenth in order; comprehending all those with papilionaceous and hermaphrodite flowers, and leguminous seed-vessels. See BOTANY.

DIADEM, in antiquity, a head-band, or allet, worn by kings, as a badge of their royalty. It was made of silk, thread, or wool, and tied round the temples and forehead, the ends being tied behind, and let fall on the neck. It was usually white, and quite plain, though sometimes embroidered with gold, and set with pearls and precious stones. In latter times, it came to be twisted round crowns, laurels, &c. and even appears to have been worn on divers parts of the body.

DIADEM, in heraldry, is applied to certain circles or rims, serving to inclose the crowns of sovereigns and to bear the globe and cross, or the flower-de-luces for their crest.

DIÆRESIS, in surgery, an operation serving to divide and separate the part when the continuity is a hindrance to cure. See SURGERY.

DIÆRESIS, in medicine, is the consuming of the vessels of an animal body. See MEDICINE.

DIÆRESIS, in grammar, the division of one syllable into two, which is usually noted by two points over a letter, as aulai instead of aulæ, dissoluenda for dissolvenda.

DIÆTETÆ, in Grecian antiquity, a kind of judges, of which there were two sorts, the cleroti and diallac-

tæii. The former were public arbitrators, chosen by lot to determine all causes exceeding ten drachms, within their own tribe, and from their sentence an appeal lay to the superior courts.

DIAGNOSTIC, in medicine, a term given to those signs which indicate the present state of a disease, its nature and cause. See MEDICINE.

DIAGONAL, in geometry, a right line drawn across a quadrilateral figure, from one angle to another, by some called the diameter. Thus *ab* in plate Miscel. fig. 41. is called a diagonal. It is demonstrable, 1. That every diagonal divides a parallelogram into two equal parts. 2. That two diagonals drawn in any parallelogram bisect each other. 3. A line *f g*, passing through the middle point of the diagonal of a parallelogram, divides the figure into two equal parts. 4. That the diagonal of a square is incommensurable with one of its sides. 5. That the sum of the squares of the diagonals of every parallelogram is equal to the sum of the squares of the four sides.

DIAGRAM, in geometry, a scheme for explaining and demonstrating the properties of any figure, whether triangle, square, circle, &c.

DIAGRAM, among musicians (from the Greek), the name given by the ancients to the table, or model, representing all the sounds of their system.

DIAL, or sun-dial, is a plane, upon which lines are described in such a manner, that the shadow of a wire, or of the upper edge of a plate stile, erected perpendicularly on the plane of the dial, may show the true time of the day. The edge of the plate by which the time of the day is found, is called the stile of the dial, which must be parallel to the earth's axis; and the line on which the said plate is erected, is called the substile. The angle included between the substile and stile, is called the elevation, or height of the stile.

Those dials whose planes are parallel to the plane of the horizon, are called horizontal dials; and those dials whose planes are perpendicular to the plane of the horizon, are called vertical or erect dials.

Those erect dials, whose planes directly front the north or south, are called direct north or south dials; and all other erect dials are called decliners, because their planes are turned away from the north or south.

Those dials, whose planes are neither parallel nor perpendicular to the plane of their horizon, are called inclining or reclining dials, according as their planes make acute or obtuse angles with the horizon; and if their planes are also turned aside from facing the south or north, they are called declining-inclining or declining-reclining dials.

The intersection of the plane of the dial, with that of the meridian, passing through the stile, is called the meridian of the dial, or the hour-line of XII.

Those meridians, whose planes pass through the stile, and make angles of 15, 30, 45, 60, 75, and 90 degrees with the meridian of the place (which marks the hour-line of 12), are called hour-circles; and their intersections with the plane of the dial, are called hour-lines.

In all declining dials, the substile makes an angle with the hour-line of XII; and this angle is called the distance of the substile from the meridian.

The declining plane's difference of longitude, is the angle formed at the intersection of the stile and plane of the dial, by two meridians; one of which passes through the hour-line of XII, and the other through the substile.

We shall now proceed to explain the different principles of their construction.

The universal principle on which dialing depends.—If the whole earth *a P c p* (Plate XLI. fig. 1.) were transparent and hollow, like a sphere of glass, and had its equator divided into twenty-four equal parts by so many meridian semicircles, *a*, *b*, *c*, *d*, *e*, *f*, *g*, &c. one of which is the geographical meridian of any given place, as London (which is supposed to be at the point *a*); and if the hours of XII were marked at the equator, both upon that meridian and the opposite one, and all the rest of the hours in order on the rest of the meridians; those meridians would be the hour-circles of London: then, if the sphere had an opake axis, as P E *p*, terminating in the poles P and *p*, the shadow of the axis would fall upon every particular meridian and hour, when the sun came to the plane of the opposite meridian, and would consequently show the time at London, and at all other places on the meridian of London.

Horizontal dial.—If this sphere was cut through the middle by a solid plane AB CD, in the rational horizon of London, one half of the axis EP would be above the plane, and the other half below it; and if straight lines were drawn from the centre of the plane, to those points where its circumference is cut by the hour-circles of the sphere, those lines would be the hour-lines of a horizontal dial for London: for the shadow of the axis would fall upon each particular hour-line of the dial, when it fell upon the like hour-circle of the sphere.

Vertical dials.—If the plane which cuts the sphere be upright, as A F C G (fig. 2), touching the given place (London) at F, and directly facing the meridian of London, it will then become the plane of an erect direct south dial; and if right lines be drawn from its centre E, to those points of its circumference where the hour-circles of the sphere cut it, these will be the hour-lines of a vertical or direct south dial for London, to which the hours are to be set as in the figure (contrary to those on a horizontal dial); and the lower half E *p* of the axis will cast a shadow on the hour of the day in this dial, at the same time that it would fall upon the like hour-circle of the sphere, if the dial-plane was not in the way.

Inclining and reclining dials.—If the plane (still facing the meridian) be made to incline, or recline, by any given number of degrees, the hour-circles of the sphere will still cut the edge of the plane in those points to which the hour-lines must be drawn straight from the centre; and the axis of the sphere will cast a shadow on these lines at the respective hours. The like will still hold, if the plane be made to decline by any given number of degrees from the meridian, towards the east or west: provided the declination be less than ninety degrees, or the reclination be less than the co-latitude of the place; and the axis of the sphere will be a gnomon, or stile, for the dial. But it cannot be a gnomon, when the declination is quite 90 degrees, nor when the reclination is equal to the co-latitude; because, in these two cases, the axis has no elevation above the plane of the dial.

And thus it appears, that the plane of every dial re-

presents the plane of some great circle upon the earth; and the gnomon the earth's axis; whether it be a small wire, as in the above figures, or the edge of a thin plate, as in the common horizontal dials.

The whole earth, as to its bulk, is but a point, if compared to its distance from the sun: and therefore, if a small sphere of glass be placed upon any part of the earth's surface, so that its axis be parallel to the axis of the earth; and the sphere have such lines upon it, and such planes within it, as above described; it will show the hours of the day as truly as if it were placed at the earth's centre, and the shell of the earth were as transparent as glass. See figs. 1 and 2.

But because it is impossible to have a hollow sphere of glass perfectly true, blown round a solid plane; or if it was, we could not get at the plane within the glass to set it in any given position; we make use of a wire sphere to explain the principles of dialing, by joining twenty-four semicircles together at the poles, and putting a thin flat plate of brass within it.

Dialing by the common terrestrial globe.—A common globe, of twelve inches diameter, has generally twenty-four meridian semicircles drawn upon it. If such a globe be elevated to the latitude of a given place, and turned about until any of these meridians cuts the horizon in the north point, where the hour of XII is supposed to be marked; the rest of the meridians will cut the horizon at the respective distances of all the other hours from XII. Then, if these points of distance be marked on the horizon; and the globe be taken out of the horizon, and a flat board or plate be put into its place, even with the surface of the horizon; and if straight lines be drawn from the centre of the board, to those points of distance on the horizon which were cut by the twenty-four meridian semicircles; these lines will be the hour-lines of a horizontal dial for that latitude, the edge of whose gnomon must be in the very same situation that the axis of the globe was, before it was taken out of the horizon: that is, the gnomon must make an angle with the plane of the dial, equal to the latitude of the place for which the dial is made.

If the pole of the globe be elevated to the co-latitude* of the given place, and any meridian be brought to the north point of the horizon, the rest of the meridians will cut the horizon in the respective distances of all the hours from XII, for a direct south dial, whose gnomon must make an angle with the plane of the dial, equal to the co-latitude of the place; and the hours must be set the contrary way on this dial, to what they are on the horizontal.

But if your globe have more than twenty-four meridian semicircles upon it, you must take the following method for making horizontal and south dials by it.

To construct a horizontal dial.—Elevate the pole to the latitude of your place, and turn the globe until any particular meridian (suppose the first) comes to the north point of the horizon, and the opposite meridian will cut the horizon in the south. Then, set the hour-index to the uppermost XII on its circle; which done, turn the globe westward until fifteen degrees of the equator pass under the brasen meridian, and then the hour-index will be at I (for the sun moves fifteen degrees every hour); and the first meridian will cut the horizon in the number of degrees from the north point, that I is distant from XII. Turn on, until fifteen more degrees of the equator pass under the brazen meridian, and the hour-index will be then at II, and the first meridian will cut the horizon in the number of degrees that II is distant from XII: and so, by making fifteen degrees of the equator pass under the brazen meridian for every hour, the first meridian of the globe will cut the horizon in the distances of all the hours from XII to VI, which is just ninety degrees; and then you need go no farther; for the distances of XI, X, IX, VIII, VII, and VI, in the forenoon, are the same from XII, as the distances of I, II, III, IV, V, and VI, in the afternoon: and these hour-lines continued through the centre, will give the opposite hour-lines on the other half of the dial: but no more of these lines need be drawn, than what answer to the sun's continuance above the horizon of your place on the longest day, which may be easily found.

Thus, to make an horizontal dial for the latitude of London, which is about $51\frac{1}{2}$ degrees north, elevate the north pole of the globe $51\frac{1}{2}$ degrees above the north point of the horizon, and then turn the globe, until the first meridian (which is that of London on the English terrestrial globe) cuts the north point of the horizon, and set the hour-index to XII at noon.

Then, turning the globe westward until the index points successively to I, II, III, IV, V, and VI, in the afternoon; or until 15, 30, 45, 60, 75, and 90 degrees of the equator pass under the brazen meridian, you will find that the first meridian of the globe cuts the horizon in the following numbers of degrees from the north towards the east, viz. $11\frac{3}{4}$, $24\frac{1}{4}$, $38\frac{1}{12}$, $53\frac{1}{2}$, $71\frac{1}{12}$, and 90; which are the respective distances of the above hours from XII upon the plane of the horizon.

To transfer these, and the rest of the hours to a horizontal plane, draw the parallel right lines *a c* and *b d* (fig. 3) upon that plane, as far from each other as is equal to the intended thickness of the gnomon or stile of the dial, and the space included between them will be the meridian or twelve-o'clock line on the dial. Cross this meridian at right angles with the six-o'clock line *g h*, and setting one foot of your compasses in the intersection *a*, as a centre, describe the quadrant *g e* with any convenient radius or opening of the compasses; then setting one foot in the intersection *b* as a centre, with the same radius describe the quadrant *f h*, and divide each quadrant into ninety equal parts or degrees, as in the figure.

Because the hour-lines are less distant from each other about noon, than in any other part of the dial, it is best to have the centres of these quadrants at a little distance from the centre of the dial-plane, on the side opposite to XII, in order to enlarge the hour-distances thereabout under the same angles on the plane. Thus, the centre of the plane is at C, but the centres of the quadrants at *a* and *b*.

Lay a ruler over the point *b*; and keeping it there for the centre of all the afternoon hours in the quadrant *f h*; draw the hour-line of I, through $11\frac{3}{4}$ degrees in the quadrant; the hour-line of II, through $24\frac{1}{4}$ degrees; of III,

* If the latitude be subtracted from 90 degrees, the remainder is called the co-latitude, or complement of the latitude. See GEOGRAPHY.

through $38\frac{1}{12}$ degrees; IV through $53\frac{1}{2}$, and V through $71\frac{1}{15}$: and because the sun rises about four in the morning on the longest days at London, continue the hour-lines of IV and V, in the afternoon, through the centre *b* to the opposite side of the dial. This done, lay the ruler to the centre *a* of the quadrant *e g*, and through the like divisions or degrees of that quadrant, viz. $11\frac{2}{3}$, $24\frac{1}{4}$, $38\frac{1}{12}$, $53\frac{1}{2}$, and $71\frac{1}{15}$, draw the forenoon hour-lines of XI, X, IX, VIII, and VII; and because the sun sets not before eight in the evening on the longest days, continue the hour-lines of VII and VIII in the forenoon, through the centre *a*, to VII and VIII in the afternoon; and all the hour-lines will be finished on this dial; to which the hours may be set, as in the figure.

Lastly, through $51\frac{1}{2}$ degrees of either quadrant, and from its centre, draw the right line *a g* for the hypothenuse or axis of the gnomon, *a g i*; and from *g*, let fall the perpendicular *g i*, upon the meridian line *a i*, and there will be a triangle made, whose sides are *a g*, *g i*, and *i a*. If a plate similar to this triangle be made as thick as the distance between the lines *a c* and *b d*, and set upright between them, touching at *a* and *b*; its hypothenuse *a g* will be parallel to the axis of the world, when the dial is truly set, and will cast a shadow on the hour of the day.

The trouble of dividing the two quadrants may be saved, by means of a scale with a line of chords upon it: for if we extend the compasses from 0 to 60 degrees of the line of chords; and with that extent, as a radius, describe the two quadrants upon their respective centres, the above distances may be taken with the compasses upon the line, and set off upon the quadrants. See INSTRUMENTS MATHEMATICAL.

To make an erect direct south dial.—Elevate the pole to the co-latitude of your place, and proceed in all respects as above taught for the horizontal dial, from VI in the morning to VI in the afternoon; only the hours must be reversed as in figure 4, and the hypothenuse *a g*, of the gnomon *a g f*, must make an angle with the dial-plane equal to the co-latitude of the place. As the sun can shine no longer on this dial, than from six in the morning until six in the evening, there is no occasion for having any more than twelve hours upon it.

To make an erect dial, declining from the south towards the east or west.—Elevate the pole to the latitude of your place, and screw the quadrant of altitude to the zenith. Then if the dial declines towards the east (which we will suppose it to do at present), count in the horizon the degrees of declination, from the east point towards the north, and bring the lower end of the quadrant to that degree of declination at which the reckoning ends. This done, bring any particular meridian of your globe (as suppose the first meridian) directly under the graduated edge of the upper part of the brazen meridian, and set the hour-index to XII at noon. Then, keeping the quadrant of altitude at the degree of declination in the horizon, turn the globe eastward on its axis, and observe the degrees cut by the first meridian in the quadrant of altitude (counted from the zenith) as the hour-index comes to XI, X, IX, &c. in the forenoon, or as 15, 30, 45, &c. degrees of the equator pass under the brazen meridian at these hours respectively; and the degrees then cut in the quadrant by the first meridian, are the respective distances of the forenoon hours from XII on the plane of the dial. For the afternoon hours, turn the quadrant of altitude round the zenith until it comes to the degree in the horizon opposite to that where it was placed before; namely, as far from the west point of the horizon towards the south, as it was set at first from the east point towards the north; and turn the globe westward on its axis, until the first meridian comes to the brazen meridian again, and the hour-index to XII: then, continue to turn the globe westward, and as the index points to the afternoon hours I, II, III, &c. or as 15, 30, 45, &c. degrees of the equator pass under the brazen meridian, the first meridian will cut the quadrant of altitude in the respective number of degrees from the zenith, that each of these hours is from XII on the dial. And note, that when the first meridian goes off the quadrant at the horizon, in the forenoon, the hour-index shows the time when the sun will come upon this dial: and when it goes off the quadrant in the afternoon, the index will point to the time when the sun goes off the dial.

Having thus found all the hour-distances from XII, lay them down upon your dial-plate, either by dividing a semicircle into two quadrants of ninety degrees each beginning at the hour-line of XII, or by the line of chords.

In all declining dials, the line on which the stile or gnomon stands, commonly called the substile-line, makes an angle with the twelve-o'clock line, and falls among the forenoon hour-lines, if the dial declines toward the east; and among the afternoon hour-lines, when the dial declines towards the west; that is, to the left hand from the twelve-o'clock line in the former case, and to the right hand from it in the latter.

To find the distance of the substile from the twelve-o'clock line.—If your dial declines from the south towards the east, count the degrees of that declination in the horizon from the east point towards the north, and bring the lower end of the quadrant of altitude to that degree of declination where the reckoning ends: then, turn the globe until the first meridian cuts the horizon in the like number of degrees, counted from the south point toward the east; and the quadrant and first meridian will then cross one another at right angles; and the number of degrees of the quadrant which are intercepted between the first meridian and the zenith, is equal to the distance of the substile line from the twelve-o'clock line; and the number of degrees of the first meridian, which are intercepted between the quadrant and the north pole, is equal to the elevation of the stile above the plane of the dial.

If the dial declines westward from the south, count that declination from the east point of the horizon towards the south, and bring the quadrant of altitude to the degree in the horizon at which the reckoning ends; both for finding the forenoon hours, and the distance of the substile from the meridian; and for the afternoon hours, bring the quadrant to the opposite degree in the horizon, namely, as far from the west towards the north, and then proceed in all respects as above.

Thus we have finished our declining dial: and in so doing, we made four dials, viz.

1. A north dial, declining eastward by the same num-

ber of degrees; 2. a north dial, declining the same number west; 3. a south dial, declining east; and, 4. a south dial, declining west: only, placing the proper number of hours, and the stile or gnomon respectively, upon each plane. For, in the south-west plane, the substilar line falls among the afternoon hours: and in the south-east of the same declination, among the forenoon hours, at equal distances from XII. And so all the morning hours on the west decliner will be like the afternoon hours on the east decliner: the south-east decliner will produce the north-west decliner; and the south-west decliner, the north-east decliner; by only extending the hour-lines, stile, and substile, quite through the centre: the axis of the stile, or edge that casts the shadow on the hour of the day, being in all dials whatever parallel to the axis of the world, and consequently pointing towards the north pole of the heavens in north latitudes, and towards the south pole in south latitudes.

An easy method for constructing of dials.—But because every one who would like to make a dial, may perhaps not be provided with a globe to assist him, and may probably not understand the method of doing it by logarithmic calculation: we shall show how to perform it by the plain dialing-lines, or scale of latitudes and hours (see fig. 5). Scales of this kind are sold by all mathematical instrument-makers.

This is the easiest of all mechanical methods, and by much the best, when the lines are truly divided: not only the half hours and quarters may be laid down by all of them, by every fifth minute by most, and every single minute by those where the line of hours is a foot in length.

Having drawn a double meridian line *a b*, *c d* (fig. 6), on the plane intended for an horizontal dial, and crossed it at right angles by the six-o'clock line *f e* (as in fig. 3), take the latitude of your place with the compasses, in the scale of latitudes, and set that extent from *c* to *e*, and from *a* to *f*, on the six-o'clock line; then, taking the whole six hours between the points of the compasses in the scale of hours, with that extent set one foot in the point *e*, and let the other foot fall where it will upon the meridian line *c d*, as at *d*. Do the same from *f* to *b*, and draw the right lines *e d* and *f b*, each of which will be equal in length to the whole scale of hours. This done, setting one foot of the compasses in the beginning of the scale at XII, and extending the other to each hour on the scale, lay off these extents from *d* to *e* for the afternoon hours, and from *b* to *f* for those of the forenoon; this will divide the lines *d e* and *b f* in the same manner as the hour-scale is divided, at 1, 2, 3, 4, 5, and 6; on which the quarters may also be laid down, if required. Then laying a ruler on the point *c*, draw the first five hours in the afternoon, from that point, through the dots at the numeral figures 1, 2, 3, 4, 5, on the line *d e*; and continue the lines of IV and V through the centre *c* to the other side of the dial, for the like hours of the morning; which done, lay the ruler on the point *a*, and draw the last five hours in the forenoon through the dots 5, 4, 3, 2, 1, on the line *f b*: continuing the hour-lines of VII and VIII through the centre *a* to the other side of the dial, for the like hours of the evening; and set the hours to their respective lines as in the figure. Lastly, make the gnomon the same way as taught above for the horizontal dial, and the whole will be finished.

To make an erect south dial.—Take the co-latitude of the place from this scale of latitudes, and then proceed in all respects for the hour-lines as in the horizontal dial; only reversing the hours, as in fig. 2; and making the angle of the stile's height equal to the co-latitude.

The dialing-lines (fig. 5) are large enough for making a dial of nine inches or more in diameter, and they are drawn sufficiently exact for common practice, to every quarter of an hour. This scale may be cut off from the plate and pasted upon the wood or pasteboard, which will render it somewhat more exact than it is on the plate: for being rightly divided upon the copper-plate, and printed off on wet paper, it shrinks as the paper dries; but when it is wetted again, it stretches to the same size as when newly printed; and if pasted on while wet, it will remain of that size afterwards.

We shall now show how to make a dial without these helps. Divide a quadrant into 90 equal parts or degrees for taking the proper angle of the stile's elevation, which is easily done.

To describe an horizontal dial.—With any opening of the compasses, as Z L (fig. 7), describe the two semicircles L F *k* and L Q *k*, upon the centres Z and *z*, where the six-o'clock line crosses the double meridian line, and divide each semicircle into twelve equal parts, beginning at L; then connect the divisions which are equidistant from L, by the parallel lines K M, J N, H O, G P, and F Q. Draw V Z for the hypothenuse of the stile, making the angle V Z E equal to the latitude of your place; and continue the line V Z to R. Draw the line R *r* parallel to the six-o'clock line, and set off the distance *a* K from Z to Y, the distance *b* I from Z to X, *c* H from Z to W, + *d g* from Z to T, and *e* F from Z to S. Then draw the lines S *s*, T *t*, W *w*, X *x*, and Y *y*, each parallel to R *r*. Set off the distance Y *y* from *a* to 11, and from *f* to 1; the distance *x* X from *b* to 10, and from *g* to 2; *w* W from *c* to 9, and from *h* to 3; *t* T from *d* to 8, and from *i* to 4; *s* S from *e* to 7, and from *n* to 5. Then laying a ruler to the centre Z, draw the forenoon hour-lines through the points 11, 10, 9, 8, 7; and laying it to the centre *z*, draw the afternoon lines through the points 1, 2, 3, 4, 5; continuing the fore-noon lines of VII and VIII through the centre Z, to the opposite side of the dial, for the like afternoon hours; and the afternoon lines IV and V through the centre *z*, to the opposite side, for the like morning hours. Set the hours to these lines as in the figure, and then erect the stile or gnomon; and the horizontal dial will be finished.

To construct a south dial, draw the line V Z, making an angle with the meridian Z L equal to the co-latitude of your place; and proceed in all respects as in the above horizontal dial for the same latitude, reversing the hours, and making the elevation of the gnomon equal to the co-latitude.

We shall now, to render this article complete, explain the method of constructing the dialing-lines, and some others.

With any opening of the compasses, as E A (fig. 8), according to the intended length of the scale, describe the circle A D C B, and cross it at right angles by the diameters C E A and D E B. Divide the quadrant A B first into nine equal parts, and then each part into ten; so shall the quadrant be divided into ninety equal parts or degrees. Draw the right line A F B for the chord

of this quadrant, and setting one foot of the compasses in the point A, extend the other to the several divisions of the quadrant, and transfer these divisions to the line A F B by the arcs 10 10, 20 20, &c. and this will be a line of chords, divided into 90 uneqal parts; which, if transferred from the line back again to the quadrant, will divide it equally. It is plain by the figure, that the distance from A to 60 in the line of chords, is just equal to A E, the radius of the circle from which that line is made.

And therefore, in laying down any number of degrees on a circle by the line of chords, you must first open the compasses, so as to take in just 60 degrees upon that line, as from A to 60: and then, with that extent as a radius, describe a circle which will be of the same size with that from which the line was divided: which done, set one foot of the compasses in the beginning of the chord line, as at A, and extend the other to the number of degrees you want upon the line, which extent, applied to the circle, will include the like number of degrees upon it.

Divide the quadrant C D into 90 equal parts, and from each point of division draw right lines as *i*, *k*, *l*, &c. perpendicular to the line E C, which will divide it into a line of sines; and although these are seldom put among the dialing-lines on a scale, yet they assist in drawing the line of latitudes. For, if a ruler be laid upon the point D, and over each division in the line of sines, it will divide the quadrant C B into 90 unequal parts, as B *a*, *a b*, &c. shown by the right lines 10 *a*, 20, *b*, 30 *c*, &c. drawn along the edge of the ruler. If the right line B C be drawn, subtending this quadrant, and the nearest distances B *a*, B *b*, B *c*, &c. be taken in the compasses from B, and set upon this line in the same manner as directed for the line of chords, it will make a line of latitudes B C, equal in length to the line of chords A B, and of an equal number of divisions, but unequal as to their lengths.

Draw the right line D G A, subtending the quadrant D A; and parallel to it, draw the right line *r s*, touching the quadrant D A at the numeral figure 3. Divide this quadrant into six equal parts, as 1, 2, 3, &c. and through these points of division draw right lines from the centre E to the line *r s*, which will divide it at the points where the six hours are to be placed, as in the figure. If every sixth part of the quadrant be subdivided into four equal parts; right lines drawn from the centre though these points of division, and continued to the line *r s*, will divide each hour upon it into quarters.

A dial on a Card.—In fig. 9, we have the representation of a portable dial, which may be easily drawn on a card, and carried in a pocket-book. The lines *a d*, *a b*, and *b c*, of the gnomon, must be cut quite through the card; and as the end *a b* of the gnomon is raised occasionally above the plane of the dial, it turns upon the uncut line *c d* as on a hinge. The dotted line A B must be slit quite through the card; and the thread must be put through the slit, and have a knot tied behind, to keep it from being easily drawn out. On the other end of this thread is a small plummet D, and on the middle of it a small bead for showing the time of the day.

To rectify this dial, set the thread in the slit right against the day of the month, and stretch the thread from the day of the month over the angular point where the curve-lines meet at XII; then shift the bead to that point on the thread, and the dial will be rectified.

To find the hour of the day, raise the gnomon (no matter how much or how little), and hold the edge of the dial next the gnomon towards the sun, so that the uppermost edge of the shadow of the gnomon may just cover the shadow-line; and the bead then playing freely on the face of the dial, by the weight of the plummet, will show the time of the day among the hour-lines, as it is forenoon or afternoon.

To find the time of sun-rising and setting, move the thread among the hour-lines, until it either covers some one of them, or lies parallel betwixt any two; and then it will cut the time of sun-rising among the forenoon hours, and of sun-setting among the afternoon hours, on that day of the year for which the thread is set in the scale of months.

To find the sun's declination, stretch the thread from the day of the month over the angular point at XII, and it will cut the sun's declination, as it is north or south, for that day, in the arched scale of north and south declination.

To find on what days the sun enters the signs; when the bead, as above rectified, moves along any of the curve lines which have the signs of the zodiac marked upon them, the sun enters those signs on the days pointed out by the thread in the scale of months.

The construction of this dial is very easy, especially if the reader compares it all along with fig. 10, as he reads the following explanation of that figure.

Draw the occult line A B (fig. 10), parallel to the top of the card, and cross it at right angles with the six-o'clock line E C D; then upon C, as a centre, with the radius C A, describe the semicircle A E L, and divide it into twelve equal parts (beginning at A), as A *r*, A *s*, &c. and from these points of division, draw the hour-lines *r*, *s*, *t*, *u*, *v*, E, *w*, and *x*, all parallel to the six-o'clock line E C. If each part of the semicircle be subdivided into four equal parts, they will give the half-hour lines and quarters, as in fig. 9. Draw the right line A S D *o*, making the angle S A B equal to the latitude of your place. Upon the centre A describe the arch R S T, and set off upon it the arcs S R and S T, each equal to $23\frac{1}{2}$ degrees, for the sun's greatest declination; and divide them into $23\frac{1}{2}$ equal parts, as in fig. 9. Through the intersection D of the lines E C D and A D *o*, draw the right line F D G at right angles to A D *o*. Lay a ruler to the points A and R, and draw the line A R F through $23\frac{1}{2}$ degrees of south declination in the arc S R; and then laying the ruler to the points A and T, draw the line A T G through $23\frac{1}{2}$ degrees of north declination in the arc S T: so shall the lines A R F and A T G cut the line F D G in the proper length for the scale of months. Upon the centre D, with the radius D F, describe the semicircle F *o* G; and divide it into six equal parts, F *m*, *m n*, *n o*, &c. and from these points of division draw the right lines *m h*, *n i*, *p k*, and *q l*, each parallel to *o* D. Then setting one foot of the compasses in the point F, extend the

other to A, and describe the arc A Z H for the tropic of ♑; with the same extent, setting one foot in G, describe the arc A E O for the tropic of ♋. Next setting one foot in the point *h*, and extending the other to A, describe the arc A C I for the beginnings of the signs ♒ and ♌; and with the same extent, setting one foot in the point *l*, describe the arc A N for the beginnings of the signs ♊ and ♎. Set one foot in the point *i*, and having extended the other to A, describe the arc A K for the beginnings of the signs ♓ and ♍; and with the same extent, set one foot in *k*, and describe the arc A M for the beginnings of the signs ♉ and ♏. Then, setting one foot in the point D, and extending the other to A, describe the curve A L for the beginnings of ♈ and ♎; and the signs will be finished. This done, lay a ruler from the point A over the sun's declination in the arch R S T (found by the following table) for every fifth day of the year; and where the ruler cuts the line F D G, make marks; and place the days of the months right against these marks, in the manner shown by fig. 9. Lastly, draw the shadow-line P Q, parallel to the occult line A B; make the gnomon, and set the hours to their respective lines, as in fig. 9, and the dial will be finished.

The following table shows the sun's place and declination, in degrees and minutes, at the noon of every day of the second year after leap-year; which is a mean between those of leap-year itself, and the first and third years after. It is useful for inscribing the months and their days on sun-dials, and also for finding the latitudes of places.

TABLE,

Showing the Sun's Place, and Declination, and the Equation of Time for every Day of the Year, calculated for the Second Year after Leap Year.

JANUARY.				FEBRUARY.

24	3 53	19 18	12 26	24	5 14	9 36	13 37	24
25	4 54	19 4	12 40	25	6 14	9 14	13 28	25
26	5 55	18 49	12 53	26	7 14	8 52	13 18	26
27	6 56	18 34	13 6	27	8 14	8 29	13 8	27
28	7 57	18 18	13 18	28	9 15	8 7	12 57	28
29	8 58	18 2	13 29	29				
30	9 58	17 46	13 39	30				
31	10 59	17 30	13 49	31				

In these tables, N. signifies North, and S. South, Declination. The signs + and —, denotes that the equation of time must be added to, or substracted from, the time shewn by a sun dial, or apparent time, in order to obtain the mean time, or the time shewn by a well-regulated clock or watch.

TABLE,

Showing the Sun's Place and Declination, and the Equation of Time for every Day of the Year, calculated for the Second Year after Leap Year.

MARCH.

	31	9 11	23 9	3 13

To find the latitude of any place by observation.—The latitude of any place is equal to the elevation of the pole above the horizon of that place. Therefore it is plain, that if a star was fixed in the pole, there would be nothing required to find the latitude, but to take the altitude of that star with a good instrument. But although there is no star in the pole, yet the latitude may be found by taking the greatest and least altitude of any star that never sets: for if half the difference between these altitudes be added to the least altitude, or subtracted from the greatest, the sum or remainder will be equal to the altitude of the pole at the place of observation.

But because the length of the night must be more than 12 hours, in order to have two such observations; the sun's meridian altitude and declination are generally made use of for finding the latitude, by means of its complement, which is equal to the elevation of the equinoctial above the horizon; and if this complement be subtracted from 90 degrees, the remainder will be the latitude, concerning which the following rules seem to take in all the various cases.

1. If the sun has north declination, and is on the meridian, and to the south of your place, subtract the declination from the meridian altitude (taken by a good quadrant), and the remainder will be the height of the equinoctial or complement of the latitude north.

EXAMPLE.

Suppose the sun's meridian altitude	42°	20′	south
And his declination, subt.	10	15	north
Remains the complement of the latitude	32	5	
Which subtract from	90	0	
And the rem. is the latitude	57	55	north.

2. If the sun has south declination, and is southward of your place at noon, add the declination to the meridian altitude; the sum, if less than 90 degrees, is the complement of the latitude north: but if the sum exceeds 90 degrees, the latitude is south: and if 90 be taken from that sum, the remainder will be the latitude.

EXAMPLES.

The sun's meridian altitude	65°	10′	south
The sun's declination, add	15	30	south
Complement of the latitude	80	40	
Subtract from	90	0	
Remains the latitude	9	20	north
The sun's meridian altitude	80°	40′	south
The sun's declination, add	20	10	south
The sum is	100	50	
From which subtract	90	0	
Remains the latitude	10	50	south

3. If the sun has north declination, and is on the meridian north of your place, add the declination to the north meridian altitude; the sum, if less than 90 degrees, is the complement of the latitude south: but if the sum is more than 90 degrees, subtract 90 from it, and the remainder is the latitude north.

EXAMPLES.

Sun's meridian altitude.	60°	50′	north
Sun's declination, add	20	10	north
Complement of the latitude	80	40	
Subtract from	90	0	
Remains the latitude	9	20	south
Sun's meridian altitude	70°	20′	north
Sun's declination, add	23	20	north
The sum is	93	40	
From which subtract	90	0	
Remains the latitude	3	40	north

4. If the sun has south declination, and is north of your place at noon, subtract the declination from the

north meridian altitude, and the remainder is the complement of the latitude south.

EXAMPLE.

Sun's meridian altitude	52°	30′	north
Sun's declination, subtract	20	10	south
Complement of the latitude	32	20	
Subtract this from	90	0	
And the rem. is the latitude	57	40	south.

5. If the sun has no declination, and is south of your place at noon, the meridian altitude is the complement of the latitude north: but if the sun be then north of your place, his meridian altitude is the complement of the latitude south.

EXAMPLES.

Sun's meridian altitude	38°	30′	south
Subtract from	90	0	
Remains the latitude	51	30	north
Sun's meridian altitude	38°	30′	north
Subtract from	90	0	
Remains the latitude	51	30	south.

6. If you observe the sun beneath the pole, subtract his declination from 90 degrees, and add the remainder to his altitude; the sum is the latitude.

EXAMPLE.

Sun's declination	20°	30′	
Subtract from	90	0	
Remains	69	30	add
Sun's altitude below the pole	10	20	
The sum is the latitude	79	50.	

Which is north or south, according as the sun's declination is north or south: for when the sun has south declination, he is never seen below the north pole; nor is he ever seen below the south pole, when his declination is north.

7. If the sun be in the zenith at noon, and at the same time has no declination, you are then under the equinoctial, and so have no latitude.

8. If the sun be in the zenith at noon, and has declination, the declination is equal to the latitude, north or south. These two cases are so plain, that they require no examples.

DIALECTICS, dialectica, in the literary history of the ancients, that branch of logic which taught the rules and modes of reasoning.

DIALLAGE, in mineralogy, called also resplendent hornblende. This stone was called *smaragdite* by Saussure, from the resemblance it has to emerald. It is never crystallized. Its texture is foliated, and it is easily divided into plates. The laminæ are inflexible, and the specific gravity is 3. The colour in some cases is fine green; in others it has the grey colour, and metallic lustre, of mica: it assumes all the shades of colour between these two extremes. According to Vauquelin, it is composed of

50.0	silica
13.0	lime
11.0	alumina
7.5	oxide of chromium
6.0	magnesia
5.5	oxide of iron
1.6	oxide of copper.
94.2	

DIALLING, the art of constructing all manner of dials. See DIAL.

Having described the most useful dials under the word DIAL, we now proceed to explain the philosophical principles of the art of dialling. In order to this, therefore, we are to consider, that as the time which passes between any meridian's leaving the sun, and returning to it again, is divided into 24 hours, so if we conceive a sphere to be constructed with twenty-four of these meridians, the sun will orderly come upon one of them at the beginning of every hour. Such a sphere may be represented by the figure P D S B (fig. 11), where the several meridians are represented by P 1 S, P 2 S, P 3 S, and so on to twenty-four in all; since these meridians divide the equinoctial into twenty-four equal parts, each part will contain just 15°, because $15 \times 24 = 360$, the whole circle; and since all the meridians pass through the poles of the world, the planes of those meridians all intersect each other in one common line P S, which is the axis of the sphere, therefore the said axis P S is in the plane of each of the twelve meridians. Suppose Z to be the zenith of any place, and D W B E the plane of the horizon fixed within the sphere, constructed with the twelve meridians, 1, 1; 2, 2; 3, 3; 4, 4; &c. then will the axis of the sphere P S pass through the centre of the plane at N; so that one half N P will be above the plane, and the other half N S below it. Suppose now this dialling-sphere to be suspended by the point Z, and moved about so as to have the points D and B exactly in the south and north points of the horizon, and E and W in the east and west points, then will the sphere have a situation every way similar to that of the earth and heavens with respect to the given place, and the axis of the sphere to that of the earth. The sun, therefore, shining on such a sphere, will be attended with all the same incidents, and produce all the same effects, as would happen if the said sphere were at the centre of the earth, or the centre N of the sphere coincided with the centre of the earth, because the distance between the surface and centre of the earth is insensible at the distance of the sun. Now it is evident, as the sun revolves about such a sphere, it will every hour be upon one half or other of the twelve hour-circles, viz. from midnight to noon, it will be on those parts of the circles which are in the eastern hemisphere; and from noon to midnight, it will pass over all those in the western. It is also farther evident, that while the sun is in the eastern hemisphere, it will be first below and then above the plane of the horizon, and *vice versa* on the other side. Again, when the sun is upon any of these hour-circles, by shining upon the axis it causes it to cast a shadow on the contrary side, on the plane of the horizon, on the lower or upper surface, as it is below or above the said plane. This shadow of the axis will be

precisely in the line in which the plane of the hour-circle would intersect the plane of the horizon: if, therefore, lines were drawn through the centre N, joining the points on each side the plane where the hour-circles touch it, as 4N4, 5N5, 6N6, &c. the shadow of the axis would fall on those lines at the beginning of each respective hour, and thereby indicate the hour-circle the sun is in for every hour of the day. These lines are properly called hour-lines, and among the rest that which represents the hour of 12 at noon is NB, half the meridian line DB; whence it appears that the hour-lines N1, N2, N3, &c. which serve for the afternoon, lie on the east side of the plane, and are numbered from the north to the east; and on the contrary.

It also appears, that as the sun's altitude above the plane is greater or less, the number of hour-circles the sun will possess above the horizontal plane will be also greater or less. Thus when the sun is at S in the equinoctial, its diurnal path for that day being the equinoctial circle itself ÆEQW, it is plain, since the arch Æ = EQ, the sun will apply to six hour-circles below the horizon, and to six above it, in each half of the day; and consequently that on this day the shadow will occupy but 12 of the hour-lines on each surface of the plane, beginning and ending at six. But when the sun is in the tropic of Cancer, its diurnal path for that day being the tropic itself, TCRF, it is manifest the sun in the forenoon ascends above the plane in passing between the hour-circles of 3 and 4 in the morning, and descends below it in the afternoon between the hours of 8 and 9: therefore on the summer tropic the shadow will pass over 16 of those hour-lines. On the contrary, when the sun is in the winter tropic at O, its path being then OGIII, it rises above the plane between 8 and 9, and leaves it between 3 and 4.

From what has been said it is evident, that if the circles be supposed removed, and only the horizontal plane remains, with the half of the axis above it in the same position as before, then should we have constituted a horizontal dial, every way the same with those in common use; with only the addition of a substile to render the stile very firm. Hence appears the reason why the gnomon or stile in those dials in our latitude is always directed to the north pole, and always contains such an angle PNB, with the hour of 12 line NB, as is equal to the latitude of the place. Lastly, the reason appears why the number of hour-lines on these dials exceeds not 16, and they are all drawn from 6 to 12 and 6 again on the northern part, the rest on the southern; and why the hour-line of 6 lies directly east and west, as that of 12 does north and south.

Dialling-globe, an instrument of brass or wood, with a plane fitted to the horizon, and an index, so contrived as to give a clear illustration of the principles on which dials are made.

Dialling-lines or scales, are graduated lines placed on rulers or the edges of quadrants and other instruments, to expedite the construction of dials. These are, 1. A scale of six hours, which is only a double tangent, or two lines of tangents, each of 45°, set together in the middle, and equal to the whole line of sines, with the declination set against the meridian altitudes in the latitude of the place. 2. A line of latitudes, which is fitted to the hour-scale, and is made by this canon; As the radius: to the chord of 90°: : so are the tangents of each respective degree of the line of latitudes: to the tangents of other arcs. And then the natural sines of these arches are the numbers, which taken from a diagonal scale of equal parts, shall graduate the divisions of the line of latitudes to any radius. The lines of hours and latitudes are general, for pricking down all dials with centres.

The other scales are particular, and give the several requisites for all upright declining dials by inspection. They are, 1. A line of chords. 2. A line for the substile's distance from the meridian. 3. A line for the stile's height. 4. A line of the angle of 12 and 6. 5. A line of inclination of meridians. See Dial.

Dialling-sphere, an instrument made of brass, with several semicircles sliding over each other upon a moveable horizon, serving to demonstrate the nature of spherical triangles; as well as to give the true idea of drawing dials on all sorts of planes.

DIALIUM, a genus of the monogynia order, in the diandria class of plants. The corolla is pentapetalous; no calyx; the stamina at the upper side of the receptacle. There is one species, a tree of the East Indies.

DIALOGISM, in rhetoric, is used for the soliloquy of persons deliberating with themselves, as the following of Juno, in the first Æneid of Virgil:

> Mene incepto desistere victam,
> Nec posse Italia Teucrorum avertere regem,
> Quippe vetor fatis? &c.

In this sense it is distinguished from dialogue.

DIAMETER, in geometry, a right line passing through the centre of a circle, and terminated at each side by the circumference thereof. The chief property of the diameter is, that it divides the circumference of a circle into two equal parts: hence we have a method of describing a semicircle upon any line, assuming its middle point for the centre. The diameter is the greatest of all chords. For finding the ratio of the diameter to the circumference, see Circle.

How to find the diameter of shot or shells.—For an iron ball, whose diameter is given, supposing a nine-pounder, which is nearly four inches, say the cube root 2.08 (of nine pounds), is to four inches, as the cube root of the given weight, is to the diameter sought, Or, if 4 be divided by 2.08, the cube root of 9, the quotient 1.923, will be the diameter of a one-pound shot; which being continually multiplied by the cube root of the given weight, gives the diameter required. Or by logarithms much shorter, thus: If the logarithm of 1.923, which is .283979, be constantly added to the third part of the logarithm of the weight, the sum will be the logarithm of the diameter. Suppose a shot to weight 24 pounds: add the given logarithm .283979 to .460070 the third part of the logarithm 1.3802112 of 24, the sum .7440494 will be the logarithm of the diameter of a shot weighing 24 pounds, which is 5.5468 inches.

If the weight should be expressed by a fraction, the rule is still the same: for instance, the diameter of a $1\frac{1}{2}$ pound ball, or $\frac{3}{2}$, is found by adding the logarithm .2839793 found above, to .0586971 one-third of the logarithm of $\frac{2}{3}$; the sum .3426764 will be the logarithm of the diameter required, *i. e.* 2.2013 inches.

As the diameter of the bore, or the caliber of the piece,

is made 1-20th part larger than that of the shot, according to the present practice, the following table is computed.

Diameters of the shots and calibers of English guns.

lb	0	1	2	3	4	5	6	7	8	9	
0	0	1.923	2.423	2.775	3.053	3.288	3.498	3.679	3.841	4.000	Diameter
	0	2.019	2.544	2.913	3.204	3.568	3.668	3.861	4.038	4.200	Caliber
1	4.143	4.277	4.403	4.522	4.635	4.743	4.846	4.945	5.040	5.131	Diameter
	4.349	4.490	4.623	4.748	4.866	4.981	5.088	5.192	5.292	5.368	Caliber
2	5.220	5.305	5.388	5.409	5.547	5.623	5.697	5.769	5.839	5.908	Diameter
	5.480	5 570	5.661	5.742	5.824	5.895	5.982	6 057	6.129	6.203	Caliber
3	5.975	6.041	6.105	6.168	6 230	6.290	6.350	6.408	6 465	6.521	Diameter
	6.273	6.343	6.410	6.475	6.541	6.604	6.666	6.707	5.788	6.846	Caliber
4	6.576	6.631	6.684	6.737	6.789	6.640	6 890	6.940	6.989	7.037	Diameter
	6.904	6.962	7.018	7.076	7.123	7.182	7.234	7.287	7.338	7.388	Caliber

The numbers in the first horizontal line are units, and those in the first vertical column tens; the other numbers, under the one, and opposite to the others, are the respective diameters of shot and calibers. Thus, to find the diameter of the shot, and the caliber of a 24-pounder, look for the number 2 on the left hand side, and for 4 at top; then the number 5.547, under 4, and opposite 2, will be the diameter of the shot in inches and decimals, and the number 5.824, under the first, the caliber of a 24-pounder, &c.

Diameters of leaden bullets, from 1 *to* 29 *in the pound.*

	0	1	2	3	4	5	6	7	8	9
0	0	1.671	1.326	1.158	1.05	.977	.919	.873	.835	.803
1	.715	.51	.730	.711	.693	.677	.663	.650	.637	.626
2	.615	.605	.596	.587	.579	.571	.564	.557	.550	.544
3	.538	.536	.526	.521	.517	.511	.506	.501	.497	.493

The diameter of musket-bores differs about 1-50th part from that of the bullet. The government allows 11 bullets in the pound for the proof of muskets, and 14 in the pound, or 29 in two pounds, for service; 17 for the proof of carbines, and 20 for service; 28 in the pound for proof of pistols, and 34 for service.

DIAMETER *of a curve*, is a right line AC (Pl. XLIII. Miscel. fig. 42.) bisecting the right lines DE, DE, drawn parallel to one another; and either of a finite or infinite length. Though a right line, bisecting all parallel lines drawn from one point of a curve to another, is taken in a strict sense only for the diameter of a curve line, yet it may not be amiss more generally to define a diameter in saying that it is that line, whether right or curve, which bisects all parallels drawn from one point of a curve to another, so that, according to this, every curve will have a diameter: and then *sir* Isaac Newton's curves of the second order have all either a right-lined diameter, or else the curves of some one of the conic sections for diameters; and many geometrical curves of the higher orders may also have for diameters curves of more inferior ones, and that *ad infinitum*. See CURVE.

DIAMETER *of a sphere*, is the diameter of the semicircle, by whose rotation the sphere is generated; in which sense it is the same with axis. See AXIS.

DIAMETER *of gravity*, in any surface or solid, is that line in which the centre of gravity is placed. See CENTER OF GRAVITY.

DIAMETER, in astronomy. The diameters of the planets are either apparent or real: the apparent diameters are such as they appear to the eye; and being measured by a micrometer, are found different in different circumstances and parts of their orbit. See ASTRONOMY.

The mean apparent diameters of the planets, as seen from the sun, are as follows:

Merc.	Ven.	Ear.	Moon	Mars	Jup.	Sat	Her.
20″	30″	17″	6″	11″	37″	16″	4″

DIAMOND, is a precious stone, which has been known from the remotest ages. When pure, it is perfectly transparent like crystal, but much more brilliant. Its figure varies considerably; but most commonly it is crystallized in the form of a six-sided prism, terminated by a six-sided pyramid. It is the hardest of all bodies; the best-tempered steel makes no impression on it. Diamond-powder can only be obtained by grinding one diamond against another. Its specific gravity is rather more than 3.5. It is a nonconductor of electricity.

As the diamond is not affected by a considerable heat, it was for many ages considered as incombustible. Sir Isaac Newton, observing that combustibles refract light more powerfully than other bodies, and that the diamond possesses this property in great perfection, suspected it, from that circumstance, to be capable of combustion. This singular conjecture was verified in 1694 by the Florentine academicians, in the presence of Cosmo III. grand duke of Tuscany. By means of a burning-glass, they consumed several diamonds. Francis I. emperor of Germany, afterwards witnessed the destruction of several more in the heat of a furnace. These experiments were repeated by Rouelle, Macquer, and Darcet; who proved that the diamond was not merely evaporated, but actually burnt; and that if air was excluded, it underwent no change.

No attempt, however, was made to ascertain the product till 1772. Lavoisier, in a Memoir published that year, showed that when the diamond is burnt, carbonic acid gas is obtained, and that there is a striking analogy between it and charcoal. In 1785, Guyton-Morveau found that the diamond is combustible when dropped in-

to melted nitre; that it burns without leaving any residuum, and in a manner analogous to charcoal. This experiment was repeated with more precision by Mr. Tennant in 1797. The conclusion which he drew from it was, that when a diamond is burnt the whole of the product is carbonic acid gas; that a given weight of diamond yields just as much carbonic acid gas as the same weight of charcoal; and that diamond and charcoal are both composed of the very same substance. The conclusion that diamond is nothing else than charcoal, was directly contrary to what one would have expected from comparing the two substances together. Their colour, hardness, specific gravity, and electrical properties, are exceedingly different: nor do they resemble each other more nearly in their combustibility. Charcoal takes fire at a read heat; and when once kindled in oxygen gas continues to burn till it is wholly consumed. According to Morveau, the diamond, before it can be burnt, must be exposed to the sun's rays in the focus of a large burning glass, or to a heat not under 5000°. But sir George M'Kenzie found that diamonds will burn in a muffle, when heated no higher than 14° or 15° Wedgewood; which must be considerably lower than 5000° Fahrenheit. Its surface assumes a black colour like charcoal: this crust is soon wasted, and another is formed in its place. It was in this manner that a diamond weighing 3.089 grains troy, gradually wasted away completely when exposed by Morveau for one hour and 40 minutes in the focus of the celebrated burning glass of Tschirnhausen, while a thermometer exposed to the sun stood at 104°.

Morveau found that one part of diamond during its combustion combines with 4.592 parts of oxygen, and the carbonic acid gas formed amounts to 5.592 parts: consequently, carbonic acid gas is composed of one part of diamond and 4.592 of oxygen; or, which is the same thing, 100 parts of carbonic acid gas are composed of

17.88 diamond
82.12 oxygen

100.00

But Lavoisier ascertained that one part of charcoal, when burnt, combines with 2.5714 parts of oxygen, and forms 3.5714 parts of carbonic acid gas: consequently, 100 parts of carbonic acid gas are composed of

28 Charcoal,
72 oxygen.

100.

But 100 parts of carbonic acid gas are also composed of 17.88 diamond, and 82.12 oxygen. We have therefore this equation:

Diamond. Oxygen. Char. Oxygen.
17.88 + 82.12 = 28 + 72.

Consequently, subtracting 72 parts of oxygen from both sides of the equation, we have

Diamond. Oxygen.
17.88 + 10.12 = 28 charcoal.

That is to say, 28 parts of charcoal are composed of 17.88 diamond and 10.12 oxygen. Of course, 100 parts of charcoal are composed of

63.85 diamond,
36.15 oxygen.

100.00

Thus we see why diamond and charcoal possess different properties: the one is a simple substance; the other is a compound of the diamond and oxygen, or it is what the French chemists call an oxide of diamond. The diamond, then, is that substance in a state of purity to which Lavoisier and his associates gave the name of carbon, as they supposed, but the oxide of carbon.

Diamond-mines are found only in the East Indies, and in Brazil in South America; in the kingdoms of Golconda, Visapour, Bengal, and the island of Borneo. There are four mines, or rather two mines and two rivers, whence diamonds are drawn. 1. The mine of Raolconda, in the province of Carnatica, five days journey from Golconda, and eight from Visapour, which has been discovered about 200 years. 2. That of Gani, or Coolour, seven days journey from Golconda eastwardly. It was discovered 140 years ago by a peasant, who, digging in the ground, found a natural fragment of twenty-five carats. 3. That of Sonmelpour, a large town in the kingdom of Bengal, near the diamond-mine. This is the most ancient of all, and should rather be called that of Gonal, which is the name of the river, in the sand whereof these stones are found. Lastly, the fourth mine, or rather the second river, is that of Succudan, in the island of Borneo.

The diamond, we have already observed, is the hardest of all precious stones. It can only be cut and ground by itself and its own substance. To bring it to that perfection which augments its price so considerably, they begin by rubbing several against each other while rough, after having first glued them to the ends of two wooden blocks, thick enough to be held in the hand. It is this powder thus rubbed off the stones, and received in a little box for the purpose, that serves to grind and polish the stones. Diamonds are cut and polished by means of a mill, which turns a wheel of soft iron sprinkled over with diamond-dust mixed with oil of olives. The same dust well ground and diluted with water and vinegar, is used in the sawing of diamonds; which is performed with an iron or brass wire, as fine as a hair. Sometimes, in lieu of sawing the diamonds, they cleave them, especially if there are any large shivers in them. But the Europeans are not usually daring or expert enough to run the risk of cleaving, for fear of breaking.

The first water in diamonds, means the greatest purity and perfection of their complexion, which ought to be that of the purest water. When diamonds fall short of this perfection, they are said to be of the second or third water, &c. till the stone may be properly called a coloured one: for it would be an impropriety to speak of an imperfectly coloured diamond, or one that has other defects, as a stone of a bad water only.

Mr. Boyle has observed, from a person much conversant in diamonds, that some of these gems, in their rough state, were much heavier than others of the same size, especially if they were cloudy or foul. With regard to their specific gravities, Mr. Ellicot, who made many experiments, has drawn out a table of their several differences with great care and accuracy. This, taking in all the common varieties in diamonds, may indeed serve as a general rule for their mean gravity, and differences. From this the mean specific gravity of the Brasil dia-

monds appears to be 3513; of East India diamonds, 3519; the mean of both, 3517. Therefore, if any thing is to be concluded as to the specific gravity of the diamond, it is, that it is to water as 3517 to 1000.

For the valuation of diamonds of all weights Mr. Jefferies lays down the following rule. He first supposes the value of a rough diamond to be settled at 2*l.* per carat at a medium; then to find the value of diamonds of greater weights, multiply the square of their weight by 2, and the product is the value required: *e. g.* To find the value of a rough diamond of two carats: $2 \times 2 = 4$, the square of the weight; which, multiplied by 2, gives 8*l.* the true value of a rough diamond of two carats. For finding the value of manufactured diamonds, he supposes half their weight to be lost in manufacturing them; and therefore, to find their value, we must multiply the square of double their weight by 2, which will give their true value in pounds. Thus, to find the value of a wrought diamond weighing two carats; we first find the square of double the weight, viz. $4 \times 4 = 16$; then $16 \times 2 = 32$. So that the true value of a wrought diamond of two carats is 32*l.* On these principles Mr. Jefferies has constructed tables of the price of diamonds from 1 to 100 carats.

The largest diamond ever known in the world is one belonging to the king of Portugal, which was found in Brasil. It is still uncut: and Mr. Magellan informs us, that it was of a larger size; but a piece was cleaved or broken off by the ignorant countryman who chanced to find this great gem, and tried its hardness by the stroke of a large hammer upon the anvil. This prodigious diamond weighs 1680 carats: and though uncut, Mr. Rome de l'Isle says that it is valued at 224 millions sterling; which gives the estimation of 79.36 or about 80 pounds sterling for each carat, viz. for the multiplicand of the square of its whole weight. The famous diamond in the sceptre of the emperor of Russia, weighs 779 carats, and is worth at least 4,854,728 pounds sterling, although it hardly cost 135,417 guineas. This diamond originally was one of the eyes of a Malabarian idol named Scheringham; and a French grenadier, who had deserted from the Indian service, contrived to become one of the priests of that idol, and by that means to steal it. After passing through several hands, the late prince Orloff purchased it at Amsterdam in 1766, for his sovereign the empress of Russia. The diamond of the great Mogul is cut in rose, weighs $279\frac{9}{16}$ carats, and is worth 380,000 guineas, though it has a small flaw near the bottom: and Tavernier, who fully examined it, valued the carat at 150 French livres. Another diamond belonging to the king of Portugal weighs 215 carats, is extremely fine, and is worth at least 369,800 guineas. The diamond of the emperor of Germany weighs $139\frac{1}{2}$ carats, and is worth at least 109,520 guineas. It is said this diamond has a little hue of a citron colour. The diamond once the property of the late unfortunate king of France, called the *Pitt* or *Regent*, weighs $136\frac{3}{4}$ carats: this gem is worth at least 208,333 guineas, although it did not cost above half that sum. Another diamond of the same monarch, called the *Sancy*, weighs 55 carats, cost 25,000 guineas, and is said to be worth much more.

Diamond, *brilliant*, is that which is cut in faces both at top and bottom; and whose table, or principal face at top, is flat. To make a complete square brilliant, if the rough diamond is not found of a square figure, it must be made so: and if the work is perfectly executed, the length of the axis will be equal to the side of the square base of the pyramid. Jewellers then form the table and collet by dividing the block or length of the axis into 18 parts. To render a brilliant perfect, each corner of the table-diamond must be shortened by 1-20th of its original. The corner ribs of the upper sides must be flattened or run towards the centre of the table 1-6th less than the sides; the lower part, which terminates in the girdle, must be 1-8th of one side of the girdle; and each corner rib of the under side must be flattened at the top to answer the above flatt ning at the girdle, and at bottom must be 1-4th of each side of the collet. The parts of the small work which completes the brilliant or the star and skill facets, are of a triangular figure. Both of these partake equally of the depth of the upper sides from the table to the girdle, and meet in the middle of each side of the table and girdle, as also at the corners. Thus they produce regular lozenges on the four upper sides and corners of the stone. The triangular facets, on the under sides, joining to the girdle, must be half as deep again as the above facets, to answer to the collet part. The stone here described is said to be a full-substanced brilliant. If the stone is thicker than in the proportion here mentioned, it is said to be an over-weighted brilliant. If the thickness is less than in this proportion, it is called a spread brilliant. The beauty of brilliants is diminished from their being either over-weighted or spread. The true proportion of the axis or depth of the stone to its side is as 2 to 3. Brilliants are distinguished into square, round, oval, and drops, from the figure of their respective girdles.

Diamond, *Cornish*, a name given by many people to the crystals found in digging the mines of tin in Cornwall. These crystals are of the nature of the Kerry-stone of Ireland, but somewhat inferior to it. They are usually bright and clear, except towards the root, where they are coarse and foul, or whitish. They are usually found in the common form of a hexangular column, terminated at each end by an hexangular pyramid.

Diamond, *rose*, is one that is quite flat underneath, with its upper part cut in many little faces, usually triangles, the uppermost of which terminate in a point. In rose-diamonds the depth of the stone from the base to the point must be half the breadth of the diameter of the base of the stone. The diameter of the crown must be two-thirds of the diameter of the base. The perpendicular, from the base to the crown, must be three-fifths of the diameter of the stone. The lozenges which appear in all circular rose-diamonds, will be equally divided by the ribs that form the crown; and the upper angles or facets will terminate in the extreme point of the stone, and the lower in the base or girdle.

Diamond, *rough*, is the stone as nature produces it from the mine. It should be chosen uniform, of a good shape, transparent, not quite white, and free from flaws and shivers. Black, rugged, dirty, flawy, veiny stones, and all such as are not fit for cutting, are pounded in a steel mortar made for that purpose; and when pulverized, the dust serves to saw, cut, and polish the rest. Shivers are occasioned by the miners atttempting to get them more easily out of the vein, which winds be-

tween two rocks, by breaking the rocks with huge iron levers, which shake, and thus fill the stone with cracks and shivers. The ancients had two mistaken notions with regard to the diamond: the first, that it became soft by steeping it in hot goat's blood; and the second, that it is malleable, and bears the hammer.

Diamonds and precious stones may be imported duty-free, saving the duty granted to the East India company on diamonds imported from any place within the limits of their character. 6 Geo. II. c. 7. s. 1. 2.

Diamond, in the glass trade, an instrument used for squaring the large plates or pieces; and, among glaziers, for cutting their glass. These diamonds are differently managed. That used for large pieces, as looking-glasses, is set in an iron ferule, about two inches long, and a quarter of an inch in diameter; the cavity of the ferule being filled up with lead, to keep the diamond firm: there is also a handle of box or ebony fitted to the ferule, and by which it is held.

Diamond, in heraldry, a term used for expressing the black colour in the achievements of peerage. Guillim does not approve of blazoning the coats of peers by precious stones instead of metals and colours; but the English practice allows it. Morgan says the diamond is an emblem of fortitude.

DIANÆ arbor or Arbor Lunae, in chemistry, the beautiful crystallizations of silver dissolved in aqua-fortis, to which some quicksilver is added; and so called from their resembling the trunk, branches, leaves, &c. of a tree. See Argentum Arborescens.

DIANDRIA, the name of the second class in Linnæus's sexual system, consisting of hermaphrodite plants, which, as the name imports, have flowers with two stamina or male organs. The orders in this class are three, derived from the number of styles or female parts. Most plants with two stamina have one style; as jessamine, lilac, privet, veronica, and bastard alaternus: vernal grass has two styles; pepper, three.

DIANTHERA, in botany, a genus of the monogynia order, in the diandria class of plants, and in the natural method ranking under the 40th order, prsonatæ. The corolla is ringent; the capsule bilocular, parting with a spring at the heel; the stamina each furnished with two antheræ, placed alternately. There are 12 species.

DIANTHUS, clove-gilliflower, carnation, pink, sweet-william, &c. a genus of the digynia order, in the decandria class of plants, and in the natural method ranking under the 22d order, caryophyllei. The calyx is cylindrical and monophyllous, with four scales at the base. There are five petals, with narrow heels; the capsule is cylindrical and unilocular. There are 30 species; but not more than four that have any considerable beauty as garden-flowers, each of which furnishes some beautiful varieties.

1. The caryophyllus, or clove-gilliflower, including all the varieties of carnation. It rises with many short trailing shoots from the root, with long, very narrow, ever-green leaves; and amidst them upright slender flower-stalks, from one to three feet high, emitting many side-shoots; all of which, as well as the main stalk, are terminated by large solitary flowers, having short oval scales to the calyx, and crenated petals. The varieties of this are very numerous, and unlimited in the diversity of flowers.

2. The deltoides, or common pink, rises with numerous short leafy shoots crowning the root, in a tufted head close to the ground, with small narrow leaves; and from the ends of the shoots many erect flower-stalks, from about 6 to 15 inches high, terminated by solitary flowers of different colours, single and double, and sometimes finely variegated. This species is perennial, as all the varieties of it commonly cultivated also are.

3. The chinensis, Chinese, or Indian pink, is an annual plant, with upright firm flower-stalks, branching erect on every side, a foot or 15 inches high, having all the branches terminated by solitary flowers of different colours and variegations, appearing from July to November.

4. The barbatus, or bearded dianthus, commonly called sweet-william. This rises with many thick leafy shoots, crowning the root in a cluster close to the ground, with spear-shaped evergreen leaves, from half an inch to two inches broad. The stems are upright and firm, branching erect two or three feet high, having all the branches and main-stem crowned by numerous flowers in aggregate clusters of different colours and variegations. The culture of these is very generally known.

DIAPASON, in music. By this term the ancient Greeks expressed the interval of the octave: and certain musical instrument-makers have a kind of rule or scale, called the diapason, by which they determine the measures of the pipes, or other parts of their instruments. There is a diapason for trumpets and serpents: bell-founders have also a diapason for the regulation of the size, thickness, weight, &c. of their bells. Diapason is likewise the appellation given to certain stops in an organ. See Stop.

Diapason diapente (from the Greek), the interval compounded of an octave and a fifth conjoined; a twelfth.

Diapason diatessaron (from the Greek), the interval compounded of an octave and a fourth conjoined; an eleventh.

DIAPENSIA, in botany, a genus of the pentandria-monogynia class of plants, the flower of which consists of one saucer-like petal, the tube being cylindrical, and the limb divided into five obtuse and plane segments; the fruit is a trilocular roundish capsule, containing a great many roundish seeds. There is one species.

DIAPENTE, in the ancient music, an interval marking the second of the concords; and, with the diatessaron, an octave. This is what in the modern music is called a fifth.

DIAPERED, or Diapre', in heraldry, the dividing of a field in planes, like fretwork, and filling the same with variety of figures.

DIAPHRAGM, in anatomy, a large, robust, musculous membrane or skin, placed transversely in the trunk, and dividing the thorax from the abdomen, whence the Latin writers call it septum transversum. See Anatomy.

DIARRHŒA. See Medicine.

DIARTHROSIS. See Anatomy.

DIASCORDIUM, in pharmacy, a celebrated composition so called from scordium, one of its ingredients.

it is otherwise termed *confectio fracastorii*. See PHARMACY.

DIASTOLE, among physicians, signifies the dilatation of the heart, auricles, and arteries; and stands opposed to the systole, or contraction of the same parts. See PHYSIOLOGY.

DIASTOLE, in grammar, a figure of prosody, whereby a syllable naturally short is made long: such is the first syllable of Priamides, in the following verse of Virgil:

Atque hic Priamides: nihil ô tibi, amice, relictum.

DIASTYLE. See ARCHITECTURE.

DIATESSARON, in music (from the Greek), a term applied by the ancient Greeks to that interval which we call a fourth; consisting of a greater tone, a lesser tone, and one greater semitone. The word is now used for the four gospels, arranged after the manner of a harmony.

DIATESSARON, in pharmacy, the name of a composition so called from the four ingredients it comprehends. See PHARMACY.

DIATONIC (from the Greek), a term applied by the ancient Greeks to that of their three genera, which consisted, like the modern system of intervals, of major tones and semitones. The diatonic genus has long since been considered as more natural than either the chromatic or enharmonic. Aristoxenus asserts it to have been the first, and informs us that the other two were formed from the division of its intervals.

DIATONUM INTENSUM, or sharp diatonic, the name given by musical theorists to those famous proportions of the intervals proposed by Ptolemy, in his system of that name; a system which, long after the time of this ancient speculative musician, was received in our counterpoint, and is pronounced by Dr. Wallis, Dr. Smith, and the most learned writers on harmonics, to be the best division of the scale.

DIAZEUXIS (Greek), division, separation; the name given by the ancients to the tone which separated two disjunct tetrachords. The diazeuxis was placed between the mesis and paramesis, *i. e.* between the highest note of the second tetrachord, and the lowest of the third; or between the note synnemenon, and the paramesis hyperboleon.

DICE, among gamesters, cubical pieces of bone or ivory, marked with dots on each of their faces, from one to six, according to the number of faces. Sharpers have several ways of falsifying dice: 1. By sticking a hog's bristle in them so as to make them run high or low as they please. 2. By drilling and loading them with quicksilver; which cheat is found out by holding them gently by two diagonal corners; for if false, the heavy sides will turn always down. 3. By filing and rounding them. But all these ways fall far short of the art of the dice-makers; some of whom are so dextrous this way, that sharpers will repay them with any money.

DICERA, a genus of the polyandria monogynia class and order. The petals are four, ovate and trifid; nectarium four or five emarginate corpuscules; anthers two horned. There are two species, trees of New Zealand.

DICHONDRIA, a genus of the class and order pentandria digynia. The calyx is five-leaved; corolla rotate, inferior; capsule dicoccous. There is one species, an herb of New Zealand.

DICHORD (from the Greek), the name given to the two-stringed lyre, said to have been invented by the Egyptian Mercury. Apollodorus accounts for its invention in the following manner: "Mercury," says he, "walking on the banks of the river Nile, happened to strike his foot against the shell of a tortoise, the flesh of which had been dried away by the heat of the sun, and nothing left of its contents but the nerves and cartilages; he was so pleased with the sound it produced, that he thence conceived the idea of a lyre, which he afterwards constructed in the form of a tortoise, and strung it with the dried sinews of animals."

DICHOTOMY, a term used by astronomers for that phasis or appearance of the moon, wherein she is bisected, or shows just half her disk. In this situation the moon is said to be in a quadrate aspect, or to be in her quadrature.

DICHOTOMY. See BOTANY.

[DICHROMA, in botany, a genus of the triandria monogynia class and order. The calyx one-valved, corolla none; seed one. There are three species, natives of Carolina, Georgia and Florida. (*c*)

DICKSONIA, a genus of the class and order cryptogamia filices. There are two species, one of which is supposed to be the same with the barometz or Scythian lamb.

[DICRANUM, in botany, a genus of the class cryptogamia, order musci. There are 23 species. (*c*)

DICTAMNUS, white dittany, or fraxinella, a genus of the monogynia order, in the decandria class of plants, and in the natural method ranking under the 26th order, multisiliquæ. The calyx is pentaphyllous; the petals are five and patulous; the filaments sprinkled with glandulous points; the capsules five, coalited. There are two species.

The dalbus, or fraxinella, has thick, penetrating, perennial roots, collected into a head at top, sending up erect stalks annually, two or three feet high, garnished with pinnated alternate leaves, of three or four pair of oblong stiff lobes, terminated by an odd one; and the stalks crowned by long, pyramidal, loose spikes of flowers, of white, red, and purple colours. They are very ornamental plants, and succeed in any of the common borders.

DICTATOR, in the policy of the ancient Romans, a magistrate invested with sovereign and even arbitrary power. He had power of life and death; also to raise or disband troops, make war or peace, and that without the consent either of the senate or people, or being accountable for his proceedings. He was elected by one of the consuls in the night-time on the frontiers of the commonwealth, and no where else; and the ordinary duration of his office was only for six months, during which time all other magistracies ceased, the tribuneship excepted. Whenever he appeared in public, he was attended by 24 lictors, or double the number allowed a consul. However, notwithstanding all this power, he could not go out of Italy, nor even ride on horseback during a march, without leave from the people. This office was accounted the safeguard of the

commonwealth for 400 years together, till Sylla and Cæsar, by assuming the title of perpetual dictators, converted it into tyranny, and rendered the very name odious.

DIDELPHIS, *opossum*, a genus of quadrupeds of the order of feræ. The generic character is: front teeth small, rounded; superior ten, the two middle ones longer; inferior eight, the two middle ones broader and very short; canine teeth long; grinders denticulated; tongue ciliated with papillæ; abdominal pouch, in most species, containing the teats.

The animals of this highly singular genus first became known to naturalists on the discovery of the western continent, and most justly excited the admiration of the philosophic world; by the strange, and, till then, unheard-of, contrivance of nature for the protection and preservation of the young; which, instead of being exposed, like other animals, during their state of helpless imbecility, to the casualties incident to that period, were securely concealed in a pouch or receptacle situated under the body of the parent.

The opossums were long supposed to be peculiar to America; but later discoveries have evinced that several species, unknown to America, exist in other parts of the globe. The following are the most remarkable species:

1. Didelphis Virginiana, or Virginian opossum. This, which seems to have been the species first discovered in America, is not much inferior in size to a cat, but is of a thicker form, owing to the length and upright growth of the fur. The general measure seems to be about one foot four inches from the nose to the tail, which is commonly about a foot or thirteen inches long. It is an animal of an elegant aspect; having a long sharpened face, and very wide mouth, armed with very numerous sharp teeth: the tail is blackish at its origin, and covered with longish hair; but from that part to the end is naked, and covered with a scaly skin, the divisions of which are marked in such a manner as to give the tail very much the appearance of a whitish snake: it is strongly prehensile, or possessed of the power of coiling, like those of several monkeys, round any object from which the animal pleases to suspend itself. Its general colour is a dingy yellowish white; the legs blackish; the belly is white, and its lower part, in the female, is furnished with a large cavity or receptacle, which can be opened and closed at pleasure: in this are situated the teats; and in it the young, immediately after birth, are either placed by the parent animal, or introduce themselves; for this is one of those particulars in natural history which hitherto seem to have eluded investigation: it is, however, more than probable that the parent herself places them there; since, even long after their residence in it, they are void of hair, and resemble fœtuses or embryos, strongly adhearing to the teats. When they have attained sufficient growth and strength, they emerge, after which they occasionally take refuge in the same receptacle on the appearance of any danger, and are carried about by the parent. This is the practice with most of the opossum tribe: but there are two species which have no ventral pouch for the reception of their young, but a kind of depression or furrow in its stead.

When imported into Britain, the opossums have never been known to breed; the late Mr. John Hunter having frequently procured several for this purpose, but could by no means succeed in his endeavours to ascertain the particulars of their history in this respect. The kangaroo however, which is an example of a similar contrivance of nature, has afforded opportunities of illustrating the subject more satisfactorily.

The Virginian opossum, like all the other American species, is a carnivorous animal, and preys on poultry, small birds, &c. in the manner of the European polecat: it is also frugivorous, eating several kinds of roots, fruits, &c. It is of a gentle disposition, and may easily be tamed; but like some other species, it has a disagreeable smell: its voice is a sort of grunting squeak; its pace in running is not swift, but it is very expert in climbing trees, and readily passes, by means of its clinging tail, from bough to bough, in the manner of a monkey. The female produces four or five at a birth, and has the power of closing the pouch so strongly as to make it extremely difficult to open it by the hand; nor will any torture compel the animal to loosen it. This power of strongly closing the pouch is performed by certain bones and muscles which nature has provided for that purpose. These were observed and described by the celebrated Cowper, in the last century, as also by Dr. Tyson. The female, when ready to produce her young, is said to make herself a nest of dry grass, in some bush, near the root of a tree. See plate XLII. Nat. Hist. fig. 165.

3. Didelphis marsupialis, or Molucca opossum. This, which is a larger species than the former, is of a thinner or more slender habit than the Virginian opossum, with the snout longer, and the mouth wider in proportion. The count de Buffon, however, considers it as the same species, and accuses Seba of negligence or ignorance in representing it as a native of the East Indies, contending that all the animals of this genus are natives of the New World. Subsequent discoveries, however, have amply justified Seba's account of its residence, specimens having been frequently imported from the India islands, &c. Its colour is a moderately deep brown, paler beneath; the ears are moderately large, and somewhat longer in proportion than in the Virginian opossum, or not of so rounded a form; the tail nearly similar to that of the Virginian; but the superior size and thinner form both of body and limbs, together with its much darker colour, sufficiently distinguish it, even at first sight, from the former species. It is reckoned a delicate food, and is said to be often seen at the tables of the great in India, where it is reared with rabbits.

3. Didelphis brachyura, or short-tailed opossum. This is one of the smaller species, and is said seldom to exceed the length of five inches from nose to tail, and in general to be somewhat smaller than this; and the tail scarcely ever exceeds the length of two inches. Its colour is a reddish-brown on the upper parts, and whitish beneath; it is destitute of an abdominal pouch, the young fastening themselves to the teats. The fur of this animal is very soft and elegant; the tail is very thick at the base, and gradually tapers to the end. It is a native of S. America.

4. Didelphis orientalis, or phalanger. The phalanger is of the size of a very large rat, measuring about nine inches from nose to tail, and the tail measures ten inches. It is a native of the Molucca islands, and is supposed to be unknown in America, though the count de Buffon informs us that the specimens which he examined were transmitted to him under the name of rats of Surinam. The colour of the phalanger is rufous grey on the upper part, and yellowish white beneath, and along the top of the head and the back runs a blackish line: the tail is hairy for about two inches and a half from the base, and the remainder is naked. Its voice is said to resemble that of a squirrel, and it often assumes the attitude of a squirrel when feeding. The muzzle is rather thick; the ears short and covered with hair: in the upper jaw are eight cutting teeth, and two in the lower.

5. Didelphis philander. The philander is about the size of a large rat; the head is large, the snout thick, and the ears rounded and upright; the tail is longer than the body, and is hairy for some little distance from the base, the remainder being naked, and towards the end prehensile. The length of the body is nine inches, and of the tail thirteen. The philander is of a reddish brown above, and whitish beneath; the eyes are surrounded with a brownish border; the mouth on each side is beset with very long vibrissæ or whiskers; down the forehead runs a brownish stripe; the thumbs on the hind feet are rounded, as in most others of this genus. It has ten upper fore teeth, of which the middle ones are rather longer than the rest; and eight lower fore teeth, the middle ones rather longest, and standing distant. It is a native of Surinam, and, in all probability, of several other parts of South America.

6. Didelphis dorsigera, or Merian opossum. This species is so named from the celebrated madame Merian, who has introduced a figure of it into her splendid work on the insects of Surinam. Madame Merian's own account of the animal as follows; "By way of filling up a plate, I have represented a kind of wood-rat, which always carries her young ones (of which there are commonly five or six) upon her back: she is of a yellowish brown colour, and white beneath. When these rats come out of their hole, either to play or to seek their food, they run about with their mother; but when they are satisfied with food, or are apprehensive of danger, they climb up again on the back of their mother, and twist their tails round that of the parent, who runs with them into her hole again."

7. Didelphis lemurina, or lemurine opossum. This is a large species, being equal in size to a cat, but longer-bodied in proportion. Its colour is a fine brownish or iron-grey above, and pale yellowish-brown beneath, in some specimens nearly white: the sides of the neck and the feet have also a tinge of this colour; the fur on the whole animal is extremely thick, rich, and soft, scarcely yielding in elegance to that of the petaurius or great flying opossum: the muzzle is short and roundish; the whiskers large and black; the ears upright, large, and a little inclining to a pointed form at the tips; the eyes bright and reddish; the hind feet furnished with a rounded interior toe; the tail, which is thick, long, and very furry, is prehensile, and is of the same colour with the body for about a fourth of its length, the remainder being black; it is naked beneath to a great distance from the tip. The general length of the body is about 18 inches, of the tail about 12.

8. Murina. In this species the tail is hairy at the base, and a fold includes the teats. It inhabits South America, and eats fruit, grain, fish, &c. It is slow and stupid. See Plate LII. Nat. Hist. fig. 164.

9. Didelphis viverrina, or viverrine opossum. This animal is remarkable for its slender form; and this, together with its sharpened visage and long brushy tail, gives it, at first view, the appearance of one of the weasel tribe rather than that of an opossum. Its general size seems to be that of a stoat, measuring about ten inches from nose to tail, and the tail itself about eight inches. It is impossible to say critically what the various forms of the teeth are adapted for from the general principles of teeth. In the front we have what may divide and tear off; behind those there are holders and destroyers; behind the latter such as will assist in mashing, as the grinders of the lion and other carnivorous animals; and, last of all, grinders to divide parts into smaller portions, as in the graminivorous tribe: the articulation of the jaw in some degree admits of all those motions.

10. Didelphis petaurus, or petaurine opossum. The size, colour, and form, of the petaurine or great flying opossum of New Holland, conspire to render it one of the most beautiful of quadrupeds. It measures about 22 inches from the tip of the nose to the beginning of the tail, which is 20 inches in length. The body is about the size of a half-grown cat or a small rabbit, and the general appearance of the animal is similar to that of a flying squirrel; an expansile membrane, covered with fur, stretching from the fore legs to the hind on each side of the body, and thus enabling the animal to spring to a considerable distance at pleasure.

The general colour of this species is a very fine sable, or deep grey-brown above, varied with a cast of ferruginous: beneath it is nearly white; a stripe of darker or blacker brown than the rest runs along the back from head to tail; the fur near the edge of the flying membrane on its upper part has also a darker tinge than on the other parts, while the edge itself is white, thus forming a beautiful contrast of colour round the whole border of the membrane; a darker or blacker shade than on the rest of the fur prevails on the upper parts of the shoulders, extending over each side of the neck. The tail is at least equal to the whole length of the head and body, and is extremely full of long, soft fur, of a blacker cast than the rest, particularly towards the end, where it is longer or more floccy than towards the base: the whole is of a roundish or subcylindric form, but from the disposition of the long fur, has a slightly flattened appearance towards the extremity.

11. Didelphis sciurea, or squirrel opossum. This is perhaps the most beautiful quadruped, if we except the petaurus or great flying opossum, of all the Australasian species yet discovered. In its general aspect is has so much the appearance of a squirrel, that, on a cursory view, it might readily pass for such. A more exact inspection into its characters will, however, evince it to be a genuine opossum. Its size is nearly that of a common squirrel; but from the fulness and particular growth of

the fur, which, like that of the lemur, grows in a suberect manner, it appears somewhat larger. Its general colour is exactly like that of the sciurus cinereus, or American grey squirrel. A black stripe passes over each eye along the top of the head: under each ear is a black patch surrounded with white, the hair on the white part having a more soft or flocculent appearance than the black. The tail, which is prehensile, is of the same colour with the body for about half its length, the remainder being black. It is very full of hair, and tapers a little towards the extremity, but without any acute termination. The eyes are black, rounded, and full: the ears round, shortish, and very thin; the whole under side of the animal is milk-white; the upper parts of the feet are also white, and the edge of the lateral or flying membrane, which extends from the fore feet to the hind, is edged with a blackish border, as in the flying squirrels. The abdominal pouch is of considerable size, and is situated, as in other opossums, on the lower part of the abdomen: the hind feet are furnished with a rounded, unarmed, or mutic thumb. Nothing can exceed the softness and delicacy of this animal's fur, which is, if possible, still finer than that of the petaurus, to which indeed, though very greatly inferior in size, as well as widely different in colour, it yet bears a striking affinity. It is a nocturnal animal, and continues torpid the greatest part of the day, but during the night is full of activity. In this, as well as in other Australian opossums, the two toes on the hind feet nearest the thumb or rounded one, are connate, or both conjoined under one common skin.

12. Didelphis pygmæa, or pygmy opossum. This is by far the most minute of all the opossums, and, from its diminutive size, not exceeding that of a common mouse, has been named the pygmy opossum. It is furnished on each side the body with an expansile membrane, exactly in the manner of the flying squirrel, by the assistance of which it is enabled to spring to a considerable distance. The fur on the whole animal is extremely fine; the colour is a soft or palish brown above, and almost white beneath; the edges of the flying membrane are also white; the nose, feet, and ears, internally are of a light pink or flesh-colour; the tail is of a flattened form, and is beautifully edged on each side with soft silky hairs. The opening of the abdominal pouch in this species is of a semilunar form: on opening this receptacle in the specimen described in the New Holland Zoology, was discovered on each side a young one, large in proportion to the parent animal, and totally destitute of hair: they had, therefore, not approached to the period of their second birth. In such specimens as were not in a pregnant state, the mammæ or teats were extremely small, and only four in number. The tongue in this animal is remarkably large and long, and of a flattened form; the hind feet have rounded and unarmed thumbs, and the two interior toes are united under a common skin.

13. Macrotarsus: tail slender, naked, hairy at the tip, heels of the hind-feet long, naked, thumb-nail flat. See Plate XLII. Nat. Hist. fig. 163, and also the article KANGAROO.

DIDELTA, a genus of the class and order syngenesia polygamia frustranea. The lyx is expanding; receptacle honey-combed into parts, which retain the seeds; down chaffy, many-leaved. There are two species, annuals of the Cape.

DIDUS, or DODO, in ornithology, a genus belonging to the order of gallinæ. The bill is contracted in the middle by two transverse rugæ; each mandible is inflected at the point; and the face is bare behind the eyes. Only one species, the ineptus, is mentioned by Linnæus. Other naturalists have added two more.

1. The dronte, or hooded dodo (ineptus, Lin.), is somewhat larger than a swan, and near three feet in length. The bill is strong, large, and hooked at the end; the gape stretches beyond the eyes: the colour is a very pale blue, except the end of the upper mandible, which is yellowish, and has a red spot on the bend of it; the end of the lower is blackish; the irides are white. The general colour of the plumage is cinereous: it is soft to the touch; the belly and thighs are whitish. The head is large, and seems covered with a black hood or cowl. The wings are very short, and of a yellowish ash-colour; the tail feathers are curled, stand up on the rump, and incline to yellow. The legs have four toes, three before and one beyind; are very stout, short, and yellowish; the claws are black. It inhabits the islands of Mauritius and Bourbon in the Indian Ocean. See Plate L. Nat. Hist. fig. 169.

2. The solitaire, or solitary dodo, is a large bird, and the male is said to weigh sometimes 45 pounds. The neck is of a proportionable length, and the eye black and lively; the head is not crested, and the general colour of the plumage is grey and brown mixed: it has scarcely any tail, and the bastard wing swells out into a round knob; the wings are too short for flight; and the hind parts are rounded like a horse's rump, being clothed with feathers, which may be termed coverts. The females are covered with sometimes brown and sometimes light-yellow feathers, and appear very beautiful. The feathers on each side of the breast enlarge into two white tufts, somewhat resembling the bosom of a woman. Those of the thighs are rounded at the end like shells; and, according to Leguat, the bird has altogether a noble and elegant gait. This is an inhabitant of the isle of Rodrigue, where it is not uncommon; but not met with in flocks, scarcely more than two being found together. It makes its nest in by-places, of leaves of the palm, a foot and a half in thickness, and lays one egg, bigger than that of a goose. The male sits in his turn, and does not suffer any bird to approach within 200 yards of the spot while the hen is sitting, which is seven weeks. The young is some months before it can shift for itself; the old ones, in the mean time, are affectionate to it, and faithful to each other afterwards, though they occasionally may mix with others of their kind. The young birds, though timid, are stupid enough to suffer the approach of any one: but when grown up, are more shy, and will not be tamed. They are chased in the winter season, viz. from March to September, being then fat, and the young birds are much esteemed for the table.

3. The Nazarene dodo is larger than a swan. The bill is a little bent downwards, and large; instead of feathers, the whole is covered over with a black down; but the wings are feathered, and it has some frizzled ones upon the rump, which serve instead of a tail; the

legs are long and scaly, and there are three toes on each foot. This was met with in the Isle of France, and described as above by Fr. Cauche; who adds, that the female lays only one egg, which is white, and as big as a penny-loaf, and that there is always found with it a white stone of the size of a hen's egg; that it makes a nest of leaves and dry herbs in the forests on the ground; and that there is likewise found a grey stone in the gizzard of the young bird.

[DIDYMODON, in botany, a genus of the class cryptogamia, order musci. (c)

DIDYNAMIA, the name of the 14th class in Linnæus's sexual method, consisting of plants with hermaphrodite flowers, which have four stamina or male organs, two of which are long and two short. See Botany.

[DIERVILLA, in botany, a genus of the class pentandria, order monogynia. The calyx is five-leaved; the corolla is five-leaved, luted, frutescent; the capsule inferior, four-celled, many seeded. There is but one species known, the D. canadensis, or yellow-flowered diervilla. (c)

DIES, in common law, are of two kinds, dies juridici, and non juridici. Dies juridici, or fasti, are all days wherein justice is administered in court. Dies non juridici, or nefasti, are all Sundays in the year: and, in Easter term, the feast of ascension of our Lord; in Trinity term, the nativity of St. John the Baptist; in Michaelmas term, the feasts of all saints and all souls, and in Hilary term, the purification of the Blessed Virgin.

Dies datus, is a day, or time of respite, given by the court to the defendant in a cause.

DIESIS, (from the Greek,) the name given to the smallest interval used in the music of the ancient Greeks. In harmonic calculations, those are called diesis which are greater than a comma, and less than a semi-tone. Diesis, in modern music, is the name given to the elevation of a note above its natural pitch. This raising of the sound is, however, only a kind of insensible gliding through the interval of a semi-tone, and does not produce any change in the denomination of the note upon which it operates. With some authors, diesis is only another name for the quarter of a tone.

DIET. See Materia Medica.

Diet or Dyet, in matters of policy, is used for the general assembly of the states or circles of the empire of Germany, and formerly of Poland, to deliberate and concert measures proper to be taken for the good of the public. The general diet of the empire is usually held at Ratisbon: it consists of the emperor, the ten electors, and the ecclesiastical princes; viz. the archbishops, bishops, abbots, and abbesses; the secular princes, who are dukes, marquises, counts, viscounts, or barons; and the representatives of the imperial cities. It meets on the emperor's summons, and any of the princes may send their deputies thither in their stead. The diet makes laws, raises taxes, determines differences between the several princes and states, and can relieve the subjects from the oppressions of their sovereigns.

DIEU et mon droit, *God and my right*, the motto of the royal arms of England, first assumed by king Richard I. to intimate that he did not hold his empire in vassalage of any mortal authority. It was afterwards taken by Edward the Third, and was continued without interruption to the time of king William III. who used the motto *je maintiendray*, though the former was still retained upon the great seal. After him, queen Anne used the motto *semper eadem*, which had been before used by queen Elizabeth; but ever since queen Anne, *dieu et mon droit* continues to be the royal motto.

Dieu son act, words anciently often used in our law: and to this day, it is a maxim in law, that the act of God shall prejudice no man: therefore, if a house is blown or beaten down by a tempest, thunder, or lightning, the lessee, or tenant for life or years, shall be quit of an action of waste; and, by the law, he has likewise a special interest or liberty allowed to take timber, to rebuild the house for his habitation.

DIFFERENCES, in heraldry, certain additaments to coat armour, whereby something is added or altered to distinguish younger families from the elder.

DIFFERENTIAL calculus. See Calculus differentialis.

DIFFERENTIO, differentialis calculus, is a method of differencing differential quantities.

We have observed, under the word Calculus, that the differential of a quantity is expressed by the letter d prefixed to it, as the differential of x is called dx; we are to remark, therefore, in this place, that the differential of dx, is ddx; and the differential of ddx, is $dddx$; ... or, as sir Isaac Newton would express it, $\dot{x}$, &c. These differentials may be expressed more compendiously thus, d^2x, d^3x, &c. whence we have powers or degrees of differentials. The differential of an ordinary quantity, is called a differential of the first degree, as dx. The differential of the second degree, is an infinitesimal of a differential quantity of the first degree, as ddx, $dxdx$, or dx^2, $dxdy$, &c. The differential of the third degree, is an infinitesimal of a differential quantity of the second degree, as $dddx$, dx^3, $dxdydz$, and so on.

The powers of differentials are differenced after the same manner as the powers of ordinary quantities: and as compound differentials either multiply or divide each other, or are perfect or imperfect powers of differentials of the first degree, the differentio-differentialis calculus is in effect the same with the differential calculus. See Calculus differentialis.

DIGASTRICUS, in anatomy, a muscle of the lower jaw, called also biventer.

DIGESTION, in medicine, is the dissolution of the aliments into such minute parts as are fit to enter the lacteal vessels, and circulate with the mass of blood.

There is a very great difference in the quantity of aliment which animals require, and in the time which they can pass without it. In general, those animals which are most active require most, and those which are most indolent require least food. The cause of this is obvious: the bodies of animals do not remain stationary, they are constantly wasting; and the waste is proportional to the activity of the animal. Hence the body must receive, from time to time, new supplies, in place of what has been carried off. The use of food answers this purpose.

We are much better acquainted with the food of animals than of vegetables. It consists of an infinite va-

riety of animal and vegetable substances: for there are but very few of either which some animal or other does not use as food. Man uses as food chiefly the muscles of animals, the seed of certain grasses, and a variety of vegetable fruits. Almost all the inferior animals have particular substances on which they feed exclusively. Some of them feed on animals, others on vegetables. Man has a greater range; he can feed on a very great number of substances. To enumerate these substances would be useless, as we are not able to point out with accuracy what it is which renders one substance more nourishing than another.

Many substances do not serve as nourishment at all; and some, instead of nourishing, destroy life. These last are called poisons. Some poisons act chemically, by decomposing the animal body. The action of others is not so well understood.

The food is introduced into the body by the mouth, and almost all animals reduce it to a kind of pulpy consistence. In man and many other animals this is done in the mouth by means of teeth, and the saliva with which it is there mixed; but many other animals grind their food in a different manner. After the food has been thus ground, it is introduced into the stomach, where it is subjected to new changes. The stomach is a strong soft bag, of different forms in different animals: in man it has some resemblance to the bag of a bagpipe. In this organ the food is converted into a soft pap, which has no resemblance to the food when first introduced. This pap has been called chyme.

Since chyme possesses new properties, it is evident that the food has undergone some changes in the stomach, and that the ingredients of which it was composed have entered into new combinations.

The formation of chyme, in fact, is owing to the stomach; and it has been concluded, from the experiments of Stevens, Reaumur, Spallanzani, Scopoli, Brugnatelli, Carimini, &c. that its formation is brought about by the action of a particular liquid secreted by the stomach, and for that reason called gastric juice.

That it is owing to the action of a liquid is evident; because, if pieces of food are inclosed in close tubes, they pass through the stomach without any farther alteration than would have taken place at the same temperature out of the body; but if the tubes are perforated with small holes, the food is converted into chyme.

This liquid does not act indiscriminately upon all substances: for if grains of corn are put into a perforated tube, and a granivorous bird is made to swallow it, the corn will remain the usual time in the stomach without alteration; whereas, if the husk of the grain is previously taken off, the whole of it will be converted into chyme. It is well known, too, that many substances pass unaltered through the intestines of animals, and consequently are not acted upon by the gastric juice. This is the case frequently with grains of oats when they have been swallowed by horses entire with their husks on. This is the case also with the seeds of apples, &c. when swallowed entire by man; yet these very substances, if they have been previously ground sufficiently by the teeth, are digested. It appears, therefore, that it is chiefly the husk or outside of these substances which resists the action of the gastric juice. We see also, that trituration greatly facilitates the conversion of food into chyme.

The gastric juice is not the same in all animals; for many animals cannot digest the food on which others live. The conium maculatum (hemlock), for instance, is a poison to man instead of food, yet the goat often feeds upon it. Many animals, as sheep, live wholly upon vegetables; and if they are made to feed upon animals, their stomachs will not digest them: others again, as the eagle, feed wholly on animal substances, and cannot digest vegetables.

The gastric juice does not continue always of the same nature, even in the same animal: it changes gradually according to circumstances. Graminivorous animals may be brought to live on animal food; and after they have been accustomed to this for some time, their stomachs become incapable of digesting vegetables. On the other hand, those animals which naturally digest nothing but animal food may be brought to digest vegetables.

What is the nature of the gastric juice, which possesses these singular properties? It is evidently different in different animals; but it is a very difficult task, if not an impossible one, to obtain it in a state of purity. Various attempts have indeed been made by very ingenious philosophers to procure it; but their analysis of it is sufficient to show us, that they have never obtained it in a state of purity.

The methods which have been used to procure gastric juice are, first, to kill the animal whose gastric juice is to be examined, after it has fasted for some time. By this method Spallanzani collected 37 spoonfuls from the two first stomachs of a sheep. It was of a green colour, undoubtedly owing to the grass which the animal had eaten. He found also half a spoonful in the stomach of some young crows which he killed before they had left their nest.

Small tubes of metal pierced with holes, and containing a dry sponge, have been swallowed by animals; and when vomited up, the liquid imbibed by the sponge is squeezed out. By this method, Spallanzani collected 481 grains of gastric juice from the stomachs of five crows.

A third method consists in exciting vomiting in the morning, when the stomach is without food. Spallanzani tried this method twice upon himself, and collected one of the times, 1 oz. 32gr. of liquid; but the pain was so great, that he did not think proper to try the experiment a third time. Mr. Gosse, however, who could excite vomiting whenever he thought proper, by swallowing air, has employed that method to collect gastric juice.

Spallanzani has observed that eagles throw up every morning a quantity of liquor, which he considers as gastric juice; and he has availed himself of this to collect it in considerable quantities.

It is almost unnecessary to remark how imperfect these different methods are, and how far every conclusion drawn from the examination of such juices must deviate from the truth. It is impossible that the gastric juice, obtained by any one of these processes, can be pure; because in the stomach it must be constantly mixed with large quantities of saliva, mucus, bile, food, &c. It may be questioned, indeed, whether any gastric juice at all can be obtained by these methods; for as the intention

of the gastric juice is to convert the food into chyme, in all probability it is only secreted, or at least thrown into the stomach, when food is present.

We need not be surprised, then, at the contradictory accounts concerning its nature, given us by those philosophers who have attempted to examine it; as these relate not so much to the gastric juice, as to the different substances found in the stomach. The idea that the gastric juice can be obtained by vomiting, or that it is thrown up spontaneously by some animals, is, to say the least of it, very far from being probable.

According to Brugnatelli, the gastric juice of carnivorous animals, as hawks, kites, &c. has an acid and resinous odour, is very bitter, and not at all watery; and is composed of an uncombined acid, a resin, an animal substance, and a small quantity of muriat of soda. The gastric juice of herbivorous animals, on the contrary, as goats, sheep, &c. is very watery, a little muddy, has a bitter saltish taste, and contains amonia, an animal extract, and a pretty large quantity of muriat of soda. Mr. Carminati found the same ingredients: but he supposes that the ammonia had been formed by the putrefaction of a part of their food, and that in reality the gastric juice of these animals, is of an acid nature.

The accounts which have been given of the gastric juice of man are so various, that it is not worth while to transcribe them. Sometimes it has been found of an acid nature, at other times not. The experiments of Spallanzani are sufficient to show, that this acidity is not owing to the gastric juice, but to the food. He never found any acidity in the gastric juice of birds of prey, nor of serpents, frogs, and fishes. Crows gave an acidulous gastric juice only when fed on grain; and he found that the same observation holds with respect to dogs, herbivorous animals, and domestic fowls. Carnivorous birds threw up pieces of shells and coral without alteration; but these substances were sensibly diminished in the stomachs of hens, even when inclosed in perforated tubes. Spallanzani himself swallowed calcareous substances inclosed in tubes; and when he fed on vegetables and fruits, they were sometimes altered and a little diminished in weight, just as if they had been put into weak vinegar; but when he used only animal food, they came out untouched. According to this philosopher, whose experiments have been by far the most numerous, the gastric juice is naturally neither acid nor alkaline. When poured on the carbonat of potass, it causes no effervescence.

Such are the result of the experiments on the juices taken from the stomach of animals. No conclusion can be drawn from them respecting the nature of the gastric juice. But from the experiments which have been made on the digestion of the stomach, especially by Spallanzani, the following facts are established.

The gastric juice attacks the surface of bodies, unites to the particles of them, which it carries off, and cannot be separated from them by filtration. It operates with more energy and rapidity the more the food is divided, and its action is increased by a warm temperature. The food is not merely reduced to very minute parts; its taste and smell are quite changed; its sensible properties are destroyed, and it acquires new and very different ones. This juice does not act as a ferment; so far from it that it is a powerful antiseptic; and even restores flesh already putrefied. There is not the smallest appearance of such a process; indeed, when the juice is renewed frequently, as in the stomach, substances dissolve in it with a rapidity which excludes all idea of fermentation. Only a few air-bubbles make their escape, which adhere to the alimentary matter, and buoy it up to the top, and which are probably extricated by the heat of the solution.

With respect to the substances contained in the stomach, only two facts have been perfectly ascertained. The first is, that the juice contained in the stomachs of oxen, calves and sheep, invariably contains uncombined phosphoric acid, as Macquart and Vauquelin have demonstrated: the second, that the juice contained in the stomach, and even the inner coat of the stomach itself, has the property of coagulating milk and the serum of blood. Dr. Young found, that seven grains of the inner coat of a calf's stomach, infused in water, gave a liquid which coagulated more than 100 ounces of milk; that is, more than 6857 times its own weight; and yet, in all probability, its weight was not much diminished.

What the substance is which possesses this coagulating property, has not yet been ascertained; but it is evidently not very soluble in water: for the inside of a calf's stomach, after being steeped in water for six hours, and then well washed with water, still furnishes a liquor on infusion which coagulates milk: and Dr. Young found that a piece of the inner coat of the stomach, after being previously washed with water, and then with a diluted solution of carbonat of potass, still afforded a liquid which coagulated milk and serum.

It is evident, from these facts, that this coagulating substance, whatever it is, acts very powerfully; and that it is scarcely possible to separate it completely from the stomach. But we know at present too little of the nature of coagulation to be able to draw any inference from these facts. An almost imperceptible quantity of some substances seems to be sufficient to coagulate milk: for Mr. Vaillant mentions in his Travels in Africa, that a porcelain dish which he procured, and which had lain for some years at the bottom of the sea, possessed, in consequence, the property of coagulating milk when put into it; yet it communicated no taste to the milk, and did not differ in appearance from other cups.

It is probable that the saliva is of service in the conversion of food into chyme as well as the gastric juice. It evidently serves to dilute the food; and probably it may be serviceable also by communicating oxygen. The chyme, thus formed, passes from the stomach into the intestines, where it is subjected to new changes, and at last converted into two very different substances, chyle and excrementitious matter.

The chyle is a white-coloured liquid, very much resembling milk. It is exceedingly difficult to collect it in any considerable quantity, and for that reason it has never been accurately analysed. We know only in general that it resembles milk; containing, like it, an albuminous part capable of being coagulated, a serum, and globules which have a resemblance to cream. It contains also different salts; and, according to some, a substance scarcely differing from the sugar of milk.

Concerning the process by which chyle is formed from chyme, scarcely any thing is known. It does not appear

that the chyle is precisely the same in all animals; for those which are herbivorous have a greater length of intestine than those which are carnivorous. It is certain that the formation of the chyle is effected by a chemical change, although we cannot say precisely what that change is, or what the agents are by which it is produced. But that the change is chemical, is evident, because the chyle is entirely different, both in its properties and appearance, from the chyme. The chyme, by the action of the intestines, is separated into two parts, chyle and excrement: the first of which is absorbed by a number of small vessels called lacteals; the second is pushed along the intestinal canal and at last thrown out of the body altogether.

After the chyme has been converted into chyle and excrement, although these two substances remain mixed together, it does not appear that they are able to decompose each other; for persons have been known seldom or never to emit any excrementitious matter per anum for years. In these, not only the chyle, but the excrementitious matter also, was absorbed by the lacteals; and the excrement was afterwards thrown out of the body by other outlets, particularly by the skin: in consequence of which, those persons have constantly that particular odour about them which distinguishes excrement. Now in these persons it is evident that the chyle and excrement, though mixed together, and even absorbed together, did not act on each other; because these persons have been known to enjoy good health for years, which could not have been the case had the chyle been destroyed.

It has been supposed by some that the decomposition of the chyme, and the formation of chyle, are prduced by the agency of the bile, which is poured out abundantly, and mixed with the chyme, soon after its entrance into the intestines. If this theory was true, no chyle could be formed whenever any accident prevented the bile from passing into the intestinal canal: but this is obviously not the case; for frequent instances have occurred of persons labouring under jaundice from the bile-ducts being stopped, either by gall-stones or some other cause, so completely, that no bile could pass into the intestines; yet these persons have lived for a considerable time in that state. Consequently digestion, and therefore the formation of the chyle, must be possible, independant of bile.

The principal use of the bile seems to be to separate the excrement from the chyle, after both have been formed, and to produce the evacuation of the excrement out of the body. It is probable that these substances would remain mixed together, and that they would perhaps even be partly absorbed together, was it not for the bile, which seems to combine with the excrement, and by this combination to facilitate its separation from the chyle, and thus to prevent its absorption. Fourcroy supposes that the bile, as soon as it is mixed with the contents of the intestinal canal, suffers a decomposition; that its alkali and saline ingredients combine with the chyle, and render it more liquid, while its albumen and resin combine with the excrementitious matter, and gradually render them less and less fluid: and this theory is certainly very probable. The bile also stimulates the intestinal canal, and causes it to evacuate its contents sooner than it otherwise would do; for when there is a deficiency of bile, the body is constantly costive.

The excrementitious matter, then, which is evacuated per anum, consists of all that part of the food and chyme which was not converted into chyle; entirely altered, however, from its original state, partly by the decomposition which it underwent in the stomach and intestines, and partly by its combination with the resin and albumen of the bile. Accordingly, we find in it many substances which did not exist at all in the food. Thus in the dung of cows and horses there is found a very considerable quantity of benzoic acid. The excrements of animals have not yet been subjected to an accurate analysis, though such an analysis would throw much light upon the nature of digestion: for if we knew accurately the substances which were taken into the body as food, and all the new substances which were formed by digestion; that is to say, the component parts of chyle and of excrement, and the variation which different kinds of food produce in the excrement; it would be a very considerable step towards ascertaining precisely the changes produced on food by digestion.

Vauquelin has ascertained that the fæces are constantly acid, always reddening vegetable blues. They run very quckly into fermentation, becoming at first more acid, but very soon begin to exhale ammonia. Pigeon-dung contains an acid of a peculiar nature, which increases when the matter is diluted with water; but gradually gives place to ammonia, which is at last exhaled in abundance.

To the same excellent chemist we are indebted for an analysis of the fixed parts of the excrements of fowls, and a comparison of them with the fixed parts of the food; from which some very curious consequences may be deduced.

He found that a hen devoured in ten days 11111.843 grains troy of oats. These contained

136.509 gr. of phosphat of lime
219.548 silica.

356.057

During these ten days she laid four eggs; the shells of which contained 98.776 gr. phosphat of lime, and 453.417 gr. carbonat of lime. The excrements emitted during these ten days contained 175.529 gr. phosphat of lime, 58.494 gr. of carbonat of lime, and 185.266 gr. of silica. Consequently the fixed parts thrown out of the system during these ten days amounted to

274.305 gr. phosphat of lime
511.911 carbonat of lime
185.266 silica.

Given out 971.482
Taken in 356.057

Surplus 615.425

Consequently the quantity of fixed matter given out of the system in ten days exceeded the quantity taken in by 615.425 grains.

The silica taken in amounted to 219.548 gr.
That given out was only 185.266 gr.

Remains 34.282

Consequently there disappeared 34.282 grains of silica.

The phosphat of lime taken in was 136.509 gr.
That given out was . 274.305 gr.

137.796

Consequently there must have been formed, by digestion in this fowl, no less than 137.796 grains of phosphat of lime, besides 511.911 grains of carbonat. Consequently lime (and perhaps also phosphorus) is not a simple substance, but a compound, and formed of ingredients which exist in oat-seed, water, or air, the only substances to which the fowl had access. Silica may enter into its composition, as a part of the silica had disappeared; but if so, it must be combined with a great quantity of some other substance.

These consequences are too important to be admitted without a very rigorous examination. The experiment must be repeated frequently, and we must be absolutely certain that the hen has no access to any calcareous earth, and that she has not diminished in weight; because in that case some of the calcareous earth, of which part of her body is composed, may have been employed. This rigour is the more necessary, as it seems pretty evident, from experiments made long ago, that some birds at least cannot produce eggs, unless they have access to calcareous earth. Dr. Fordyce found, that if the canary-bird was not supplied with lime at the time of her laying, she frequently died, from her eggs not coming forward properly. He divided a number of these birds at the time of their laying eggs into two parties: to the one he gave a piece of old mortar, which the little animals swallowed greedily; they laid their eggs as usual, and all of them lived; whereas many of the other party, which were supplied with no lime, died.

The chyle, after it has been absorbed by the lacteals, is carried by them into a pretty large vessel, known by the name of thoracic duct. Into the same vessel likewise is discharged a transparent fluid, conveyed by a set of vessels which arise from all the cavities of the body. These vessels are called lymphatics, and the fluid which they convey is called lymph. In the thoracic duct, then, the chyle and the lymph are mixed together.

Very little is known concerning the nature of the lymph, as it is scarcely possible to collect it in any quantity. It is colourless, has some viscidity, and is said to be specifically heavier than water. It is said to be coagulable by heat; if so, it contains albumen; and from its appearance it probably contains gelatine. Its quantity is certainly considerable, for the lymphatics are very numerous.

The chyle and lymph being thus mixed together, are conveyed directly into the blood-vessels. The effect produced by their union in the thoracic duct is not known, but neither the colour nor external properties of the chyle are altered. In man, and many other animals, the thoracic duct enters at the junction of the left subclavian and carotid veins, and the chyle is conveyed directly to the heart, mixed with the blood, which already exists in the blood-vessels. From the heart, the blood and chyle thus mixed together are propelled into the lungs, where in their united state they undergo farther changes.

Such are the phenomena of digestion, as far as they have been traced. The food is first conveyed to the stomach, where by means of the gastric juice it is converted into chyme. The chyme passes into the intestinal canal, where it is subjected to a new process, being gradually decomposed and converted into chyle and excrementitious matter, which by means of the bile are separated from each other. The excrementitious matter is evacuated, but the chyle is absorbed by the lacteals, and conveyed to the blood-vessels by the lungs.

DIGESTOR, in chemistry, a strong vessel, made of copper or iron, and fitted with a close cover and screws; so as to remain perfectly tight in a considerable degree of heat, whilst water, common air, and the subject of the operation, are contained in it. The cover of the digestor should always be provided with a valve to let out a part of the steam, otherwise the vessel will certainly burst, by which it may prove fatal to the by-standers. Of all chemical vessels hitherto invented, the digestor seems best calculated for increasing the action of the menstruums. Water, confined in a digestor, is susceptible of so much heat as to melt lead; and it is frequently found to melt the solder of lead and tin, with which the copper vessel was held together: hence appears the necessity of using hard solder, made of spelter, or silver and brass, for this purpose; otherwise, the digestor cannot contain the water, when much heated, without melting in the joints. In this vessel, fresh ox-bone will be so digested in the space of a quarter of an hour, as to become soft and tender, and capable of being cut with a knife; and the water, in which it was boiled, turned into a hard jelly, and a large cake of fat on its surface, when all is properly cooled.

DIGGING, among miners, is appropriated to the operation of freeing any kind of ore from the bed or stratum in which it lies, where every stroke of their tools turns to account: in contradistinction to the openings made in search of such ore, which are called hatches or essay-hatches, and the operation itself, tracing of mines, or hatching. When a bed of ore is discovered, the beele-men, so called from the instrument they use, which is a kind of pick-ax, free the ore from the fossils around it, and the shovel-men throw it up from one *shamble* to another, till it reaches the mouth of the hatch. In some mines, to save the expense as well as fatigue of the shovel-men, they raise the ore by means of a winder, and two buckets, one of which goes up as the other comes down.

DIGIT, DIGITUS, in astronomy, the 12th part of the diameter of the sun or moon, is used to express the quantity of an eclipse. Thus an eclipse is said to be of six digits, when six of these parts are hidden.

DIGITS, or MONADES, in arithmetic, signify any integer under 10, as 1. 2. 3. 4. 5. 6. 7. 8. 9.

DIGIT is also a measure taken from the breadth of the finger. It is properly 3-4ths of an inch, and contains the measure of four barley-corns laid breadthwise.

DIGATALIS, FOX-GLOVE, a genus of the angiospermia order, in the didynamia class of plants; and in the natural method ranking under the 28th order, luridæ. The calyx is quinquepartite; the corolla campanulated, quinquefid, and ventricose; the capsule ovate and bilocular. There are 12 species; 5 of which are hardy, herbaceous, biennial, and perennial plants. The herbaceous

species rise two or three feet high, crowned with spikes of yellow iron-coloured or purple flowers. The canariensis or shrubby sort rises five or six feet high, having spear-shaped rough leaves, four or five inches long, and half as broad; the branches being all terminated with flowers growing in loose spikes. All the species are easily raised by seeds. An ointment made of the flowers of purple fox-glove and fresh butter, is much commended by some surgeons for scrophulous ulcers which run much and are ill-conditioned. Taken internally, this plant is a violent purgative and emetic; and is therefore only to be administered to robust constitutions. An infusion of two drams of the leaf in a point of water, given in half-ounce doses every two hours, till it begins to vomit or purge, is recommended in dropsy, particularly that of the breast. It is said to have produced an evacuation of water so copious and sudden, in ascites, by stool and urine, that the compression of bandages was found necessary. The use of this remedy, however, is thought dangerous by many physicians, yet the Edinburgh pharmacopœia has retained it.

DIGITATED, among botanists, an appellation given to compound leaves, each of which is composed of a number of simple foliola, placed regularly on a common petiole; though strickly speaking, there must be more than 4 foliola to make a digitated leaf.

DIGNITY ECCLESIASTICAL: ecclesiastical dignities are those of archbishop, bishop, dean, archdeacon, and prebendary, and the possessors of these dignities are called dignitaries. Of dignities and prebends, Camden reckons 544 in England.

DIGYNIA, from δις twice, and γυνη a woman, the name of an order or secondary division, in each of the first 13 classes except the 9th, in Linnæus's sexual method; consisting of plants, which to the classic character, whatever it is, add the circumstance of having two styles or female organs.

DILAPIDATION, is where an incumbent of a church-living sufferers the parsonage house or out-houses to fall down, or be in decay, for want of necessary reparations; or it is the pulling down or destroying any of the houses or buildings belonging to a spiritual living, or destroying of the woods, trees, &c. appertaining to the same; for it is said to extend to committing or suffering any wilful waste, in or upon the inheritance of the church. Deg. Pars. Couns. 89. By 13 Eliz. c. 10, if any ecclesiastical persons, who are bound to repair the buildings whereof they are seised in right of their place or function, suffer them to fall into decay for want of repair, and make fraudulent gifts of their personal estate, with intent to hinder their successors from recovering dilapidations against their executors or administrators, in such case the successor shall have like remedy in the ecclesiastical court, against the grantee of such personal estate, as he might have against the executor or administrator of the predecessor. By 14 Eliz. c. 11. all monies recovered by dilapidations, shall within two years be employed upon the buildings for which they were paid, on pain of forfeiting double so much as shall not be so employed, to the queen.

DILATATORES, see ANATOMY.

DILATORY PLEAS, are such as are put in merely for delay, and are of three kinds: 1. To the jurisdiction of the court, alleging, that it ought not to hold plea of the matter in hand, as belonging to some other court. 2. To the disability of the plaintiff, by reason whereof he is unable to commence or continue the suit, as that he is outlawed, attainted, an infant, or the like. 3. In abatement, as for some defect in the writ, as a misnomer of the defendant, or other want of form in any material respect. These pleas were formerly used as merely dilatory, without any foundation of truth, and calculated only for delay; but now by stat. 4 and 5 Anne, c. 16. no dilatory plea shall be admitted, without affidavit made of the truth thereof, or some probable matter shown to the court to induce them to believe it true. 3 Black. 301.

DILATRIS, in botany, a genus of the monogynia order, belonging to the triandria class of plants. There is no calyx; the corolla has six petals, and is shaggy; the stigma is simple. Three species, herbaceous plants of the Cape.

DILEMMA, in logic, an argument consisting of two or more propositions, which divides the whole into all its parts, or members, by a disjunctive proposition, and then infers something concerning each part, which is finally referred to concerning the whole.

DILLENIA, in botany, a genus of the polyandria-polygynia class of plants; the corolla of which consists of five coriaceous, large, roundish, and hollow petals: the fruit is roundish, and externally covered with a number of capsules, which are oblong, and divided by a furrow; within, there is a large column or pulpous receptacle: the seeds are numerous, and very small; and nidulated underneath the capsules. There are seven species, beautiful trees of the East Indies.

DIMENSION, in geometry, is either length, breath, or thickness; hence a line has one dimension, viz. length; a superficies two, viz. length and breadth; and a body or solid has three, viz. length, breadth, and thickness.

DIMENSION is used with regard to the power of the roots of an equation, which are called the dimensions of that root. Thus in a simple equation $x = a + b$, the unknown quantity is only of one dimension: in a quadratic equation $x^2 = a^2 + b^2$, it is of two dimensions: in a cubic $x^3 = a^3 + b^3$ it is of three dimensions; and so on.

DIMINUTION, in architecture, a contraction of the upper part of a column, by which its diameter is made less than that of the lower part.

DIMINUTION, in law, is where the plaintiff or defendant in a writ of error, alleges on an appeal to a superior court, that part of the record is omitted, and remains in the inferior court not certified; whereon he prays that it may be certified by certiorari. Co. Ent. 222. 242.

DIMINUTION, in music, is when there are several words which are to make tones, and several quick motions in a cadence, several quavers, semiquavers, &c. corresponding to a crochet or minim, as when a semibreve is divided into two minims, four crotchets, &c.

DIMINUTION, in rhetoric, the exaggerating what you have to say by an expression that seems to diminish it.

DIMINUTIVE, in grammar, a word formed from some other, to soften or diminish the force of it, or to signify a thing is little in its kind. Thus cellule is a diminutive of cell, globule of globe, hillock of hill.

DIMISSORY LETTERS, are such as are used where a candidate for holy orders has a title in one diocese, and is

to be ordained in another; the proper diocesan sends his letters dimissory, directed to some other ordaining bishop, giving leave that the bearer may be ordained, and have such a cure within his diocese.

DIOCESE, the circuit of every bishop's jurisdiction: for England has two sorts of divisions; one into shires or counties, in respect of the temporal state; and another into provinces, in regard to the ecclesiastical state; which provinces are divided into dioceses. The provinces are two, Canterbury and York; whereof Canterbury includes twenty-one dioceses, or sees of suffragan bishops; and York three, besides the bishopric of the Isle of Man, which was annexed to the province of York by king Henry the VIII.

DIODIA, in botany, a genus of the monogynia order, in the tetrandria class of plants; and in the natural method ranking under the 47th order, stellatæ. The corolla is monopetalous and funnel-shaped; the capsule bilocular and dispermous. There are six species.

DIODON, or SUN-FISH, a genus of fishes belonging to the order of amphibia nantes.

There are three species. 1. The atinga, grows to a great bulk; one examined by Sylvianus was above 100 pounds in weight; and Dr. Borlase mentions another taken at Plymouth, in 1734, that weighed 500 pounds. In form it resembles a bream or some deep fish cut off in the middle. The mouth is very small, and contains in each jaw two broad teeth with sharp edges. The eyes are little; before each is a small semilunar aperture; the pectoral fins are very small, and placed behind them. The colour of the back is dusky and dappled; the belly silvery: between the eyes and the pectoral fins are certain streaks pointing downwards. The skin is free from scales. When boiled, it has been observed to turn into a glutinous jelly, resembling boiled starch when cold, and serving the purposes of glue on being tried on paper and leather. The meat of this fish is uncommonly rank: it feeds on shell-fish. Care must be taken not to confound it with the sun-fish of the Irish, which differs in all respects from this. 2. The mola, or short sun-fish, differs from the former, in being much shorter and deeper. The back and the anal fins are higher, and the aperture to the gills not semilunar, but oval. The situation of the fins is the same in both; and both are taken on the western coasts of Britain, but in much greater numbers in the warmer parts of Europe. 3. The hystrix, or globe, is common to Europe and South Carolina. As yet only a single specimen has been discovered in our seas, taken at Penzance in Cornwall. The length was one foot seven; the length of the belly, when distended, one foot; the whole circumference in that situation two feet six. The form of the body is usually oblong; but when alarmed, it has the power of inflating its belly to a globular shape of great size. This seems designed as a means of defence against fish of prey; as they have less means of laying hold of it; and are besides terrified by the number of spines with which that part is armed, and which are capable of being erected on every part. The mouth is small: the irides white, tinged with red: the back from head to tail almost straight, or at least very slightly elevated; of a rich deep-blue colour. It has the pectoral, but wants the ventral fins: the tail is almost even, divided by an angular projection in the middle; tail and fins brown. The belly and sides are white, shagreened or wrinkled: and beset with innumerable sharp spines, adhering to the skin by four processes. See Plate XLII. Nat. Hist. figs. 167 and 168.

DIŒCIA, from δις twice, and οικια a house or habitation, two houses. The name of the 22d class in Linnæus's sexual method; consisting of plants which, having no hermaphrodite flowers produce male and female flowers on separate roots. These latter only ripen seeds; but require for that purpose, according to the sexualists, the vicinity of a male plant; or the aspersion, that is, sprinkling of the male dust. From the seeds of the female flowers are raised both male and female plants. The plants then in the class diœcia are all male and female: not hermaphrodite, as in the greater number of classes; nor with male and female flowers upon one root, as in the class monœcia of the same author. See BOTANY.

DIOMEDIA, in ornithology, the albatross, a genus belonging to the order of anseres. The bill is straight; the superior mandible is crooked at the point, and the lower one is truncated; the nostrils are oval, open, a little prominent, and placed on the sides. There are two species, viz. 1. The exulans, has pinnated wings, and three toes on each foot. It is the albatross of Edwards; and is about the size of a pelican. These birds are found in the ocean betwixt the tropics and at the Cape of Good Hope. They are also often seen in vast flocks in Kamtschatka, and the adjacent islands, about the end of June, where they are called geat gulls; but it is chiefly in the bay of Penschinensi, the whole inner sea of Kamtschatka, the Kurile isles, and that of Bering; for on the eastern coasts of the first, they are scarce, a single straggler only appearing now and then. Their chief motive for frequenting these places seems to be plenty of food; and their arrival is a sure presage of shoals of fish following. At their first coming they are very lean, but soon grow immensely fat. They are voracious birds, and will often swallow a salmon of four or five pounds weight; but as they cannot take the whole of it into the stomach at once, part of the tail-end will often remain out of the mouth; and the natives, finding the bird in this situation, make no difficult matter of knocking it on the head on the spot. Before the middle of August they migrate elsewhere. They are often taken by means of a hook baited with a fish; but it is not for the sake of their flesh that they are valued, it being hard and unsavoury; but on account of their intestines, a particular part of which they blow up as a bladder, to serve as floats to buoy up their nets in fishing. Of the bones they make tobacco-pipes, needle-cases, and other useful things. When caught, they defend themselves stoutly with their bills. Their cry is harsh and disagreeable, not unlike the braying of an ass. The breeding-places of the albatross, if at all in the northern hemisphere, have not yet been pointed out; but we are certain of their multiplying in the southern, viz. at Patagonia and Falkland-islands; to this last place they come about the end of September or beginning of October, among other birds, in great abundance. Their nests are made on the ground with earth, are round in shape, a foot in height, and indented at top. The egg is larger than that of a goose, four inches and a half long, white, marked with dull spots at the large end; and is thought to be good food, the white never growing hard with boil-

ing. While the female is sitting, the male is constantly on the wing and supplies her with food: during this time they are so tame as to suffer themselves to be pushed off the nest while their eggs are taken from them; but their chief destruction arises from the hawk, which, the moment the female gets off the nest, darts on it, and flies away with the egg. The albatross itself likewise has its enemy, being greatly persecuted, while on the wing, by the dark grey gull called skua. 2. The demersa, has no quill-feathers on the wings; and the feet have four toes, connected together by a membrane. It is the black penguin of Edwards, about the size of a goose, and is found at the Cape of Good Hope. It is an excellent swimmer and diver; but hops and flutters in a strange awkward manner on the land, and, if hurried, stumbles perpetually, and frequently runs for some distance like a quadruped, making use of the wings instead of legs, till it recovers its upright posture; crying out at the same time like a goose, but in a much hoarser voice. It is said to climb some way up the rocks in order to make its nest; in doing which, it has been observed to assist with its bill. The eggs are two in number, white, as large as those of a duck, and reckoned delicious eating; at least they are thought so at the Cape, where they are brought in great numbers for that purpose. At this place the birds are often kept tame; but in general they do not survive the confinement many months.

DIONÆA MUSCIPULA, or Venus's flytrap, in botany, a newly discovered sensitive plant, in the construction of which nature seems to have had some view towards its nourishment, in forming the upper joint of its leaf like a machine to catch food; and placing upon the middle of it the bait for the unhappy insect that becomes its prey. Many minute red glands that cover its inner surface, and which perhaps discharge some sweet liquor, tempt the poor insect to taste them; and the instant these tender parts are irritated by its feet, the two lobes rise up, grasp it fast, lock the two rows of spines together, and squeeze it to death. And further, lest the strong efforts for life, in the creature thus taken, should serve to disengage it, three small erect spines are fixed near the middle of each lobe among the glands, that effectually put an end to all its struggles. Nor do the lobes ever open again, while the dead animal continues there. But it is nevertheless certain, that the plant cannot distinguish an animal from any other substance; for if we put a straw or pin between the lobes, it will grasp it full as fast as if it was an insect. The plant is one of the monogynia order, in the decandria class. It grows in America, about 35 deg. N. lat. in wet shady places, and flowers in July and August. The largest leaves are about three inches long, and an inch and a half across the lobes: the glands of those exposed to the sun are of a beautiful red colour; but those in the shade are pale and inclining to green. The roots are squamous, sending forth but few fibres, and are perennial. The leaves are numerous, inclining to bend downwards, and are placed in a circular order; they are jointed and succulent; the lower joint, which is a kind of stalk, is flat, longish, two-edged, and inclining to heart-shaped. In some varieties they are serrated on the edges near the top. The upper joint consists of two lobes; each lobe is of a semi-oval form, with the margins furnished with stiff hairs like eyebrows, which embrace or lock in each other when they close: this they do when they are inwardly irritated. The upper surfaces of these lobes are covered with small red glands; each of which appears, when highly magnified, like a compressed arbutusberry. Among the glands, about the middle of each lobe, are three very small erect spines. When the lobes inclose any substance, they never open again while it continues there. If it can be pushed out so as not to strain the lobes, they expand again; but if force is used to open them, so strong has nature formed the spring of their fibres that one of the lobes will generally snap off rather than yield. The stalk is about six inches high, round, smooth, and without leaves; ending in a spike of flowers. The flowers are milk-white, and stand on footstalks, at the bottom of which is a little painted bractea or flower-leaf. The soil in which it grows, as appears from what comes about the roots of the plants when they are brought over, is a black light mould, intermixed with white sand, such as is usually found in our moorish heaths. Being a swamp plant, a north-east aspect will be properest for it at first, to keep it from the direct rays of the sun; and in winter, till we are acquainted with what cold weather it can endure, it will be necessary to shelter it with a bell-glass, such as is used for melons. This should be covered with straw or a mat in hard frosts. By this means several of these plants have been preserved through the winter in a very vigorous state. Its sensitive quality will be found in proportion to the heat of the weather, as well as the vigour of the plant. Our summers are not warm enough to ripen the seed; or possibly we are not sufficiently acquainted with the culture of it. See Plate L. Nat. Hist. fig. 170.

DIOPHANTINE PROBLEMS, in mathematics, certain questions relating to square and cube numbers, and right-angled triangles, &c. the nature of which was determined by Diophantus, a mathematician of Alexandria, who is believed to have lived about the third century. In these questions it is endeavoured to find commensurable numbers to answer indeterminate problems; which bring out an infinite number of incommensurable quantities. For example, it is proposed to find a right-angled triangle, whose sides z, y, x, are expressed by commensurable numbers; it is known that $x^2+y^2 = z^2$ being the supposed hypothenuse. But it is possible to assume x and y so, that z will be incommensurable; for if $x = 1$, and $y = 2$, z, $= \sqrt{5}$. The art of resolving such problems consists in managing the unknown quantity or quantities in such a manner, that the square or higher power may vanish out of the equation, and then by means of the unknown quantity in its first dimension, the equation may be resolved without having recourse to incommensurables.

For example, in the equation above, $x^2 + y^2 = z^2$, suppose $z = x + u$, then is $x^2 + y^2 = x^2 + 2xu + u^2$, out of which equation x^2 vanishes, and then it is $y^2 = 2xu + u^2$, which gives $x = \frac{y^2 - u^2}{2u}$. Hence, assuming y and u equal to any numbers at pleasure, the three sides of the triangle will be y, $\frac{y^2 - u^2}{2u}$, and $\frac{y^2 + u^2}{2u}$, which are all ra-

tional whenever y and u are rational. For example, if $y=3$, and $u=1$, then $\frac{y^2-u^2}{2u}=4$, and $x+u$, or $\frac{y^2+u^2}{2u}=5$. It is evident that this problem admits of infinite numbers of solutions (see Sanderson's Algebra), as y or u may be assumed infinitely various.

DIOPSIS, a genus of the vermes class and of the diptera order. Head with two inarticulate filiform horns much longer than the head, at the tip of which are placed the eyes. It inhabits South America and Guinea, and resembles the ichneumon. There is but a single species.

DIOPTRICS, the science of refractive vision; or that part of optics which considers the different refractions of light in its passing through different mediums, as air, water, glass, &c. and especially lenses. See Optics.

DIOSCOREA, in botany, a genus of the hexandria order, in the dicœcia class of plants; and in the natural method ranking under the 11th order, sarmentaceæ. The male calyx is sexpartite, there is no corolla: the female calyx is sexpartite; no corolla; three styles; the capsule trilocular and compressed; and there are two membranaceous seeds. There are 15 species, of which the only remarkable one is the sativa or yam. This has slender stalks, which trail upon the ground and extend a great way: these frequently put out roots from their joints as they lie upon the ground, by which the plants are multiplied. The roots are eaten by the inhabitants of both the Indies; and are particularly serviceable in the West India islands, where they make the greatest part of the negroes' food. The plant is supposed to have been brought from the East to the West Indies; for it has never been observed to grow wild in any part of America; but in the island of Ceylon, and on the coast of Malabar, it grows in the woods, and there are in those places a great variety of sorts. It is propagated by cutting the root in pieces, observing to preserve an eye in each, as is practised in planting potatoes. One plant will produce three or four large roots. The skin of these roots is pretty thick, rough, unequal, covered with many stringy fibres or filaments, and of a violet colour approaching to black. The inside is white, and of the consistence of red beet. It resembles the potatoe in its mealiness, but is of closer texture. When raw, the yams are vicous and clammy: when roasted or boiled, they afford very nourishing food; and are often preferred to bread by the inhabitants of the West Indies, on account of their lightness and facility of digestion. When first dug out of the ground, the roots are placed in the sun to dry: after which, they are either put into sand, dry garrets, or casks; where if kept from moisture, they may be preserved for years, without being spoiled or diminished in their goodness. The root commonly weighs two or three pounds, though some yams have weighed upwards of twenty pounds. With us it must be kept in the stove.

DIOSCURIA, in Grecian antiquity, a festival kept in honour of the Dioscuri, or Castor and Pollux, wherein the assistants shared plentifully of the gifts of Bacchus.

DIOSMA, African spiræa, a genus of the monogynia order, in the pentandria class of plants; and in the natural method ranking with those of which the order is doubtful. The corolla is pentapetalous, the nectarium crown-shaped above the germen: there are five capsules coalited; the seeds hooded. There are 19 species; of which the most remarkable are the hirsuta, with narrow hairy leaves; and the oppositifolia, with leaves placed in the form of a cross. The first is a very handsome shrub, growing to the height of five or six feet: the stalks are of a fine coral colour: the leaves come out alternately on every side of the branches, and are narrow-pointed and hairy: the flowers are produced in small clusters at the end of the shoots, and are of a white colour. They are succeeded by starry seed-vessels having five corners; in each of which corners is a cell, containing one smooth, shining, oblong, black seed: these seed-vessels abound with a resin which emits a grateful scent, as does also the whole plant. The second species rises to the height of three or four feet: the branches are slender, and produced from the stem very irregularly; the leaves are placed crosswise; the flowers are produced at the ends of the branches, between the leaves: the plants continue a long time in flower, and make a fine appearance when they are intermixed with other exotics in the open air. Both species are propagated by cuttings; which may be planted during any of the summer months in pots, and plunged into a moderate hotbed, where they should be shaded from the sun, and frequently watered. In about two months they will have taken root; when each should be transplanted into a small pot where they are to remain; but during winter, like most other exotic plants, they must be preserved in a greenhouse.

DIOSPYROS, the Indian date-plum; a genus of the dicœcia order, in the polygamia class of plants; and in the natural method ranking under the 18th order, bicornes. The calyx is hermaphrodite and quadrifid; the corolla urceolated and quadrifid; there are eight stamia; the style quadrifid; the berry octospermous: the male calyx, corolla, and stamina, as in the former. There are 9 species; the most remarkable are: 1. The lotus, which is supposed to be a native of Africa, whence it was transplanted into several parts of Italy, and also into the south of France. The fruit of this tree is supposed to be the lotus with which Ulysses and his companions were enchanted, and which made those who ate of it forget their country and relations. In the warm parts of Europe, this tree grows to the height of 30 feet. In the botanic garden at Padua, there is one very old tree which has been described by some of the former botanists under the title of guaiacum patavinum. This tree produces plenty of fruit every year; from the seeds of which many plants have been raised. 2. The Virginiana, pinshannin, persimon, or pitchumon plum, is a native of America, but particularly of Virginia and Carolina. The seeds of this sort have been frequently imported into Britain, and the trees are common in many nurseries about London. It rises to the height of 12 or 14 feet; but generally divides into many irregular trunks near the ground, so that it is very rare to see a handsome tree of this sort. Though plenty of fruit is produced on these trees, it never comes to per-

fection in England. In America the inhabitants preserve the fruit till it is rotten, as is practised with medlars in England; when it is esteemed very pleasant. Both species are propagated by seeds: and the plants require to be treated tenderly while young; but when they are grown up, they resist a great degree of cold. See Plate L. Nat. Hist. fig. 171.

DIPHTHONG, in grammar, a double vowel, or the mixture of two vowels pronounced together, so as to make one syllable.

DIPHYSA, a genus of the class and order diadelphia decandria. The cal. is half fivecleft; legume with a bladder on each side; seeds hooked. There is one species, a small tree of New Spain.

DIPSACUS, TEAZEL, a genus of the monogynia order, in the tetrandria class of plants; and in the natural method ranking under the 48th order, aggregatæ. The common calyx is polyphyllous, proper above; the receptacle paleaceous. There are four species; the most remarkable of which is the dipsacus fullonum, which grows wild in many parts of England. It is of singular use in raising the nap upon woollen cloth. For this purpose, the heads are fixed round the circumference of a large broad wheel, which is made to turn round and the cloth is held against them. In the west of England, great quantities of this plant are cultivated for the use just-mentioned. It is propagated by sowing the seeds in March, upon a soil that is well prepared. About one peck of seed is sufficient for an acre, as the plants must have room to grow; otherwise the heads will not be large enough, nor in great quantity. When the plants come up, they must be hoed in the same manner as is practised for turnips, cutting down all the weeds, and thinning the plants to about eight inches distance: and as the plants advance, and the weeds begin to grow again, they must be hoed a second time, cutting out the plants to a wider distance, so that they may finally stand a foot distant from each other. The second year they will shoot up heads, which may be cut about the beginning of August. They are then to be tied up in bunches, and set in the sun if the weather is fair; if not, in rooms to dry them. The common produce is about 160 bundles or sheaves upon an acre, which are sold for one shilling each.

DIPTERYX, a genus of the diadelphia decandria class and order. The cal. has the two upper segments winged; legume ovate, compressed, one-seeded. There are two species, tall trees of Guiana.

DIPLOMA, an instrument of licence given by colleges, societies, &c. to a clergyman to exercise the ministerial function, or to a physician to practice the profession, &c. after passing examination or admitting him to a degree.

DIPPING, among miners, signifies the interruption, or breaking off, of the veins of ore; an accident that gives them a great deal of trouble before they can discover the ore again.

DIPPING NEEDLE. See MAGNETISM, and NAVIGATION.

DIPTERE, or DIPTERON, in the ancient architecture, signified a temple surrounded with two rows of columns, which formed a sort of porticoes, called wings or isles. Pseudodiptere is the same, except that instead of the double row of columns, this was only encompassed with a row of single ones.

DIPTYCHS, in antiquity, a public register, in which were written the names of the consuls and other magistrates among the heathens; and among the Christians, they were a sort of tablets, on one of which were written the names of the deceased, and on the other those of the living patriarchs, bishops, &c. or those who had done any service to the church, for whom prayers were offered, the deacon reading the names at mass.

DIPUS, JERBOA, a genus of quadrupeds of the glires order. The generic character is, front-teeth two above and below: forelegs very short; hind-legs very long: clavicles in the skeleton.

1. Dipus sagitta, or common jerboa. This is the species which seems to have been known to the ancients under the name of μυοδιτης, or two-footed mouse, and which is represented, though with no great degree of exactness, on some coins of Cyrene, where it was anciently found in great abundance, and where it still continues. It is supposed to be the saphan of the scriptures. It is about the size of a rat, and is of a very pale tawny-brown above, and white beneath; and across the upper part of the rump runs an obscure dusky band, which is probably not a permanent character, since it appears to be more or less distinct in different individuals. The head is short; the ears thin, broad, upright, and rounded: the eyes large, round, and dark-coloured: the fore legs about an inch long, with five toes to each foot: the hind legs are extremely long, thin, sparingly covered with short hair, and very much resemble those of a bird: the hind feet have three toes each, the middle of which is somewhat longer than the rest, and all are furnished with sharp and strong claws: there is also a very small spur or back toe, with its corresponding claw.

The usual length of the common jerboa, from nose to tail, is about seven inches and a quarter: the tail is about ten inches long, of a form rather inclining to square than cylindric, and of the same colour with the body, but terminated by an elegant, flattish, oval tuft of black hair, with a white tip. On each side the nose are situated several very long hairs or whiskers, as is usual in most animals of this tribe: the cutting-teeth are sharp and strong, and resemble those of a rat. In its attitudes and manner of progressing this animal resembles a bird; generally standing, like the kangaroo, on its hind feet, and leaping with much celerity, and to a great distance: but sometimes it sets its fore feet to the ground for a moment or two, and then recovers its former attitude. It principally uses the fore legs in feeding; pulling to its mouth the ears of corn, and various other vegetable substances on which it feeds. It inhabits subterraneous holes, which it either prepares itself, or finds ready excavated, in the dry, stony, and sandy deserts in which it resides. During the day it commonly remains in its hole; coming out at night for food and exercise. On the approach of cold it is said to grow torpid for some time, reviving on the change of weather.

This animal has frequently been brought into Europe, and in a state of confinement has been known to burrow almost through a brick wall.

Sonnini, in his Egyptian Travels, assures us, that he

never was able to find any difference either in the form or colour of the Egyptian jerboa. Sonnini considers the jerboa as constituting a link between quadrupeds and birds. In this idea he is by no means singular; the same sentiment naturally suggesting itself to the mind of every philosophical observer. Mons. Sonnini adds, that though the transition from quadrupeds to birds has not yet been investigated, we have nevertheless reason to consider the connection as existing. We have the beginning of it in the jerboa, and the last link of it in the bat. We have every reason to believe, that the series of gradations will develope itself in proportion as good observers shall carry their researches into countries the natural history of which is still unexplored.

"The jerboa appears, says Sonnini, to be a prolific animal; for it is exceedingly numerous in Arabia, Nubia, Egypt, and Barbary. During my stay or rather during my excursions in Egypt, I opened several jerboas. My principal aim was to ascertain that they had only one stomach, and consequently could not possess the power of ruminating. This was in answer to one of the questions that Michaelis, professor at Gottingen, had addressed to the travellers sent to the East by the king of Denmark, viz. Whether the jerboa was a ruminating animal; a question arising from the same mistake which had occasioned the confounding the jerboa with the daman Israel, or saphan of the Hebrews.

"The sand and ruins that surround modern Alexandria are much frequented by the jerboas. They live in society, and in burrows, which they dig with their teeth and nails. I have even been told, that they sometimes make their way through the soft stone which is under the stratum of sand. Though not absolutely wild, they are very shy, and upon the least noise, or the sight of any object, retire precipitately to their holes. They can only be killed by surprise. The Arabs contrive to take them alive, by stopping up all the avenues to their burrows except one, by which they force them to come out. I never ate any: their flesh indeed is said to be not very palatable, though it is not despised by the Egyptians. Their skin, covered with soft and shining hair, is used as a common fur.

"In Egypt, I kept six of these animals for some time in a large cage: the very first night they entirely gnawed through the upright and cross pieces of wood, and I was obliged to have the inside of the cage lined with tin. They ate rice, walnuts, and all kind of fruit. They delighted in being in the sun; and when taken into the shade, huddled together, and seemed to suffer from the privation of heat. It has been said that the jerboas sleep by day, and never in the night, but, for my part, I observed quite the contrary. In a state of liberty they are found round their subterraneous habitations in open day, and those which I kept were never more lively nor awake than in the heat of the sun. Although they have a great deal of agility in their motions, they seem to be of a mild and tranquil disposition. Mine suffered themselves to be touched without difficulty; and there was neither noise nor quarrel among them, even when taking their food. At the same time they testified neither joy, fear, nor gratitude: their gentleness was neither amiable nor interesting: it appeared to be the effect of cold and complete indifference, bordering on stupidity. Three of these animals died successively, before my departure from Alexandria. I lost two others during a somewhat stormy passage to the isle of Rhodes, when the last, owing to the negligence of the person to whose care it was committed, got out of its cage and disappeared. I had a strict search made for it, when the vessel was unloaded, but without effect: it had no doubt been killed by the cats."

2. Dipus jaculus, or alagtaga, in its general appearance perfectly resembles the common or Egyptian jerboa, but is considerably larger, though there appear to be permanent varieties or races which are, on the contrary, much smaller than the common species. It is principally distinguished by the remarkable character of the hind feet, each of which has a pair of very conspicuous spurs, or additional toes, situated at some distance above the front toes, and furnished with sharp claws.

Of this species there are two supposed varieties, agreeing in form with the above-mentioned, but differing in size, and in some degree in colour; but the differences are not such as to justify our considering them as specifically distinct. The first of these varieties is the Middle Siberian jerboa, which is of the size of a rat, and has the thighs crossed by a white line; and a whitish zone or circle surrounds the nose. It is found in the eastern deserts of Siberia and Tartary, beyond the lake Baikal. It also occurs in Barbary and Syria, and extends, according to Dr. Pallas, even as far as India. The other variety is called by Mr. Pennant, the pygmy Siberian jerboa. It agrees in form with the other, but has no white circle round the nose, and has a smaller tuft to the tail, the end of which is just tipped with white. In size it is far inferior to the middle variety. It is said to inhabit the same places with the large or first-described kind. All these agree in their manners, burrowing in hard clayey ground, not only in high and dry spots, but even in low and salt places; digging their holes with great celerity with their fore feet and teeth; thus forming oblique and winding burrows, of some yards in length, and ending in a large hole or receptacle by way of nest, in which are deposited the herbs, &c. on which they feed. They are said to wander about chiefly by night. They sleep rolled up, with the head between the thighs: they are extremely nimble, and on the approach of danger spring forward so swiftly, that a man well mounted can scarcely overtake them. They are said to be particularly fond of the roots of tulips, and some other bulbous-rooted plants. They are supposed to sleep during the winter in the manner of dormice.

Mr. Bruce tells us, that there is little variety in the animal, either in size or colour; but that towards Aleppo they have broader noses than the African; that their bodies are thicker, and their colour lighter.

"The Arabs of the kingdom of Tripoli (says Mr. Bruce), make very good diversion with the jerboa, in training their grey-hounds, which they employ to hunt the gazel or antelope, after instructing him to turn himself by hunting this animal. The prince of Tunis, son of Sidi Younis, and grandson of Ali Bey, who had been strangled by the Algerines when that capital was taken, being then an exile at Algiers, made me a present of a

small greyhound, which often gave us excellent sport. It may perhaps be imagined that a chace between these two creatures could not be long: yet I have often seen, in a large inclosure, or court-yard, the greyhound employ a quarter of an hour before he could master his nimble adversary: the small size of the creature assisted him much; and had not the greyhound been a practised one, and made use of his feet as well as his teeth, he might have killed two antelopes in the time he could have killed one jerboa."

3. Dipus cafer, or cape jerboa, is by far the largest of all the jerboas, and is a native of the mountainous country to the north of the Cape of Good-Hope. Its length from nose to tail is one foot two inches: of the tail near 15 inches. It is an animal of great strength and activity, and will spring to the distance of 20 or 30 feet at once. When eating, it sits upright in the manner of a squirrel. It burrows in the ground, like the smaller kind of jerboas, with great ease and expedition, having very strong and long claws, five in number, on the fore feet: those on the hind feet are rather short, and are four in number.

4. Dipus meridianus, or torrid jerboa, according to Dr. Pallas, was first figured by Seba, whose specimen appears to have been not fully grown. Specimens were brought to Dr. Pallas in the year 1770, which were taken on the borders of the sandy desert of Naryn, in 46½ north latitude. The burrows or passages which they had formed in the dry soil, had a triple entrance, and were about an ell deep in the ground. The size of this species is between that of a rat and a field-mouse; and notwithstanding the great length of the hind legs, it does not leap, like the rest of the jerboas, but runs in the manner of the rat tribe; and it seems to be on this account that Mr. Pennant has ranked it under his division of jerboid rats, rather than among the true jerboas.

5. Dipus canadensis, or Canadian jerboa. This minute species is thus described by general Davies, who had an opportunity of examining it during his residence at Quebec.

"As I conceive there are very few persons, however conversant with natural history, who may have seen or known that there was an animal existing in the coldest parts of Canada, of the same genus with the jerboa, hitherto confined to the warmer climates of Africa, I take the liberty of stating the following particulars. With respect to the food, or mode of feeding, of this animal, I have it not in my power to speak with any degree of certainty, as I could by no means procure any kind of sustenance that could induce it to eat; therefore, when caught, it lived only a day and a half. The first I was so fortunate as to catch, was taken in a large field near the falls of Montmorenci, and by its having strayed too far from the skirts of the wood, allowed myself, assisted by three other gentlemen, to surround it, and after an hour's hard chase, to get it unhurt, though not before it was thoroughly fatigued, which might in a great measure accelerate its death. During the time the animal remained in its usual vigour, its agility was incredible for so small a creature. It always took progressive leaps of from three to four, and sometimes of five yards, although seldom above 12 or 14 inches from the surface of the grass; but I have frequently observed others in shrubby places, and in the woods, among plants, where they chiefly reside, leap considerably higher. When found in such places, it is impossible to take them, from their wonderful agility, and their evading all pursuit, by bounding into the thickest part of the covert they can find. With respect to the figure given of it in its dormant state, I have to observe, that the specimen was found by some workmen, in digging the foundation for a summer-house in a gentleman's garden, about two miles from Quebec, in the latter end of May, 1787. It was discovered enclosed in a ball of clay, about the size of a cricket-ball, nearly an inch in thickness, perfectly smooth within, and about 20 inches under ground. The man who first discovered it, not knowing what it was, struck the ball with his spade, by which means it was broken to pieces, or the ball would have been presented to me. How long it had been under ground it is impossible to say; but as I could never observe these animals in any parts of the country after the beginning of September, I conceive they lay themselves up some time in that month, or beginning of October, when the frost becomes sharp. Nor did I ever see them again before the last week in May or beginning of June. From their being enveloped in balls of clay, without any appearance of food, I conceive they sleep during the winter, and remain for that term without sustenance. As soon as I conveyed this specimen to my house, I deposited it, as it was, in a small chip box, in some cotton, waiting with great anxiety for its waking, but that not taking place at the season they generally appear, I kept it until I found it begin to smell; I then stuffed it, and preserved it in its torpid position. I am led to believe its not recovering from that state arose from the heat of my room during the time it was in the box, a fire having been constantly burning in the stove, and which in all probability was too great for its respiration."

DIRCA, a genus of the monogynia order, in the octandria class of plants, and in the natural method ranking under the 1st order, vepreculæ. There is no calyx; the corolla is tubular, with the limb indistinct; the stamina are longer than the tube; the berry is monospermous. There is one species, a small shrub of North America.

DIRECT, in astronomy. A planet is said to be direct when it appears to an observer on the earth to go forward in the zodiac, or according to the succession of the signs. See Astronomy.

Direct, in matters of genealogy, is understood of the principal line, or the line of ascendants and descendants, in contradistinction to the collateral line. The heirs in the direct lines always precede those in the collateral lines.

Direct ray, in optics, is a ray flowing from a point of visible object directly to the eye, through one and the same medium.

Direct *east and west dials*, dials drawn upon planes that directly face the east and west points of the horizon, or parallel to the meridian. See Dial.

Direct *south and north dials*, are those which face directly the north and south points of the horizon, or parallel to the prime vertical circle. See Dial.

DIRECTION, in mechanics, signifies the line or path of a body's motion, along which it endeavours to pro-

ceed, according to the force impressed upon it. See MECHANICS.

DIRECTOR, in surgery, a grooved probe to direct the edge of the knife or scissars, in opening sinuses, or fistulæ, that by this means the subadjacent vessels, nerves, and tendons, may remain unhurt. See SURGERY.

DIRIGENT, or DIRECTRIX, a term in geometry, signifying the line of motion along which the described line or surface is carried in the genesis of any plane or solid figure: thus, if the line A B (plate XLIII. Miscel. fig. 43) move along the line AC, so that the point A always keeps in the line AC, a parallelogram, as A B C D, will be formed, of which the side A B is the describent, and the line A C the dirigent; so also, if the surface A B C D be supposed to be carried along CE, in a position always parallel to itself in its first situation, the solid ADFH will be formed, where the surface AD is the describent, and the line CE the dirigent.

DISA, a genus of the gynandria diandria class and order. The spathe is one-valved; petals three, the third less, two-parted, gibbous at the base. There are four species, herbaceous plants of the Cape, with beautiful blue flowers.

DISABILITY, in law. an incapacity in a man to inherit or take a benefit which otherwise he might have done, which may happen four ways; by the act of the ancestor, by the act of the party, by the act of law, and by the act of God. 1. Disability by the act of the ancestor; as if a man be attainted of treason or felony; by this attainder his blood is corrupt, and himself and his children disabled to inherit. 2. Disability by the act of the party himself; as if one make a feoffment to another who then is sole, upon condition, that he shall enfeoff a third before marriage, and before the feoffment made, the feoffee takes a wife; he has by that disabled himself from performing the condition according to the trust reposed in him, and therefore the feoffer may enter, and oust him. Lit. 357. 3. Disability by act of law, is when a man by the sole act of the law is disabled, as an alien born, &c. 4. Disability by the act of God, is where a person is of non-sane memory, and in cases of idiocy, &c. But it is a maxim in our law, that a man of full age shall never be received to disable his own person. Co. lib. 4. 123, 124. See also ALIENS, DISSENTERS, IDIOCY, and INFAMY.

DISAGREEMENT, will make a nullity of a thing that had effect before: and disagreement may be to certain acts to make them void, &c. Co. Lit. 380.

DISANDRA, a genus of the monogynia order, in the heptandria class of plants. The calyx has seven leaves; the corolla is parted into seven, and flat; the capsule two-celled. There are two species, pretty trailing plants, natives of Madeira.

DISARMING, in law, the prohibiting people to wear arms. It is an offence by the common law of England for persons to go or ride armed with dangerous and uncommon weapons: though gentlemen may wear common armour according to their quality. It is also ordained by statute, that no persons shall come before the king's justices with force of arms, on pain of imprisonment, &c.

DISC, *discus*, in antiquity, a quoit made of stone, iron, or copper, five or six fingers broad, and more than a foot long, inclining to an oval figure, which was hurled in the manner of a bowl, to a vast distance, by the help of a leathern thong tied round the person's hand who threw it, and put through a hole in the middle.

DISC, in astronomy, the body and face of the sun and moon, such as it appears to us on the earth; or the body or face of the earth, such as it appears to a spectator in the moon. The disc in eclipses is supposed to be divided into 12 equal parts, called digits; in a total eclipse of the luminaries, the whole disc is obscured; in a partial eclipse, only a part of it. See ASTRONOMY.

DISC, in botany, is an aggregate of florets forming, as it were, a plane surface.

DISC, in optics, is the width of the aperture of telescopic glasses, whatever their form be, whether plane, convex, concave, &c.

DISCHARGE, is where a man confined by some legal process, performs that which the law requires, and is released from the matter for which he is confined. If an obligee discharge one obligor where several are jointly bound, it discharges the others. See ARREST, BOND, PAYMENT.

DISCLAIMER, is a plea containing an express denial, renouncing or disclaiming; as if the tenant sues a replevin upon a distress taken by the lord. and the lord avows, saying that he holds of him as his lord, and that he distrained for rent not paid, or service not performed; then the tenant denying to hold of such lord, is said to disclaim; and the lord proving the tenant to hold of him, the tenant loses his land. Co. on Lit. 102.

DISCONTINUANCE OF POSSESSION. A man may not enter upon his own lands or tenements alienated (such alienation being a discontinuance of possession), whatsoever his right be to them, of his own self or by his own authority, but must bring his writ, and seek to recover possession by law. Co. Rep. lib. 3. 85.

DISCONTINUANCE OF PROCESS, is where the plaintiff leaves a chasm in the proceedings of his cause, whereby the opportunity of prosecution is lost for that time, in which case he must begin again, and usually pays costs to the defendant, or the plaintiff is dismissed the court, &c. Every suit, whether civil or criminal, and every process therein, ought to be properly continued from day to day, &c. from its commencement to its conclusion; and the suffering any default or gap herein, is called a discontinuance. 2 Haw. 298.

DISCONTINUANCE OF PLEA: if where divers things should be pleaded to, then some are omitted, this is a discontinuance. 1 Nels. Abr. 660, 661.

DISCORD, in music, is a dissonant or inharmonious combination of sounds, so called in opposition to the concord, the effects of which the discord is calculated to relieve and sweeten. Among various other discords are those formed by the union of the fifth with the sixth, the fourth with the fifth, the seventh with the eighth, and the third with the ninth and seventh, all which require to be introduced by certain preparatives, and to be succeeded by concords to which they have some relation.

DISCORDANT, an epithet applied to all dissonant and inharmonious sounds, whether successive or simultaneous.

DISCOVERY, the act of revealing or disclosing any

matter by a defendant, in his answer to a bill filed against him in a court of equity. A bill for a discovery must show an interest in the plaintiff in the subject, to which the required discovery relates; and such an interest as entitles him to call on the defendant for the discovery. Finch, Rep. 36, 44. 1 Vern. 399. It is a general rule, that no one is bound to answer so as to subject himself to punishment, in whatever manner that punishment may arise. 2 Vez. 245, 451. 1 Atk. 450. 2 Atk. 393.

DISCOUNT, in commerce, a term among traders, merchants, and bankers. It is used by the two former on occasion of their buying commodities on the usual time of credit, with a condition that the seller shall allow the buyer a certain discount at the rate of so much per cent. per annum, for the time for which the credit is generally given, upon condition that the buyer pays ready money for such commodities, instead of taking the time of credit. Traders and merchants also frequently taking promissory notes for money due, payable to them or order at a certain time, and sometimes having occasion for money before the time is elapsed, they procure these notes to be discounted by bankers or others before the time of payment; which discount is more or less, according to the credit and reputation of the person who drew the note, and the indorser or indorsers. Bills of exchange are also discounted by bankers, and in this consists one article of the profits of banking. See BANK.

The best tables of discount are those of Mr. Smart, founded upon the true principles of decimal arithmetic. By these it appears, that he who allows 5*l.* for the discount of 100*l.* for one year at 5 per cent. wrongs himself, for he ought to receive so much money as at 5 per cent. interest will amount to 100*l.* in one year, and the sum is 95*l.* 4*s.* 9¼*d.* The rule for finding the true discount is this:

As the amount of 100*l.* for the given rate and time:
Is to the given sum: :
So is the interest of 100*l.* for the given rate and time:
To the discount of the debt.

Thus, if p be the principal, r the rate of interest, and t the time, then say, as $100 + rt : p : : rt : \frac{prt}{100+rt}$, which is the true discount. Hence $p - \frac{prt}{100+rt} = \frac{100p}{100+rt}$ is the present worth, or sum to be received.

Ex. Suppose it be required to find the discount of 250*l.* for five months, at the rate of 5*l.* per cent. per annum interest. Here $p = 250$, $r = 5$, and $t = \frac{5}{12}$; therefore $\frac{prt}{100+rt} = \frac{250 \times 5 \times \frac{5}{12}}{100 + 5 \times \frac{5}{12}} = \frac{250 \times 25}{1200 + 25} = \frac{250}{49} =$ 5*l.* 2*s.* $\frac{2}{49}$*d.*

The following table is an enlargement of one invented by Mr. D. Baird and will be found useful for practical purposes in trade and commerce.

Method of Calculation by the above Table.—To find the interest of any sum of money for any given number of days, multiply the sum by the number of days, and the table will show the product.

If the interest on any number of sums be required, multiply the number of pounds by the days, as above, on each sum, and add the product into one sum; the value of which, (if less than 1000*l.*) will be immediately shown by the table: and thus by the union of the respective sums, the loss or gain of fractions falls only on the gross sum, instead of each component part.

Example. On the 1st of May I want to discount a bill for 100*l.*, due the 25th of June following:

100*l.* × 40 days = 4000; by referring to the table, I find the nearest number

less than 4000 is 3923 = 10*s.* 9*d.*;

which, being deducted, leaves 77

76 = 2½*d.*

10*s.* 11½*d.* $\frac{1}{7\frac{1}{2}}$. Or (which is easier), finding that 4015 is, by the table, equal to 11 shillings; and that 15 is equal to ½*d.*, I find the answer to be 10*s.* 11½*d.*

Ex. The interest is required on the following sums:

	100*l.* for	75 days,
	245	42
	987	86
	92	140
100*l.* ×	75 days	= 7,500
245*l.* ×	42 days	= 10,290
987*l.* ×	86 days	= 84,882
92*l.* ×	140 days	= 12,880
		115,552, the nearest No. less than
this in the table, is		114,975 = 15*l.* 15*s.*, which being

subtracted, leaves 577. I find, by the table, 578 amount to 1*s.* 7*d.*; and as the unit which forms the difference is only $\frac{1}{7\frac{1}{2}}$ of a farthing, I call the answer 15*l.* 16*s.* 7*d.* strictly 15*l.* 16*s.* $6\frac{3}{4}$*d.* $\frac{6\frac{1}{2}}{7\frac{1}{2}}$

The interest of any sum may be found without the assistance of the table, by multiplying the number of pounds by the days, as above, and dividing

by 7,300 to give the product in	Pounds
by 365	Shillings
by $30\frac{5}{12}$	Pence.

The units in this table being less than $\frac{1}{4}$ of a farthing each, the fractions of these units are omitted.

DISCRETE or DISJUNCT PROPORTION, is when the ratio of two or more pairs of numbers or quantities is the same, but there is not the same proportion between all the four numbers. Thus if the numbers 3 : 6 : : 8 : 16 be considered, the ratio between 3 : 6, is the same as that between 8 : 16, and therefore the numbers are proportional; but it is only discretely or disjunctly, for 3 is not to 6 as 6 to 8; that is, the proportion is broken off between 8 and 3, and is not continued as in the following continued proportionals; 3 : 6 : : 12 : 24.

DISCRETE QUANTITY, such as is not continuous and joined together. Such is a number whose parts being distinct units, cannot be united into one continuum; for in a continuum, there are no actual determinate parts before division, but they are potentially infinite.

DISCRETION, is to discern between right and wrong; and therefore whoever has power to act at discretion, is bound by the rule of reason and law. 2 Inst. 56. 298. And the court of king's-bench has a power to redress things that are otherwise done, notwithstanding they are left to the discretion of those that do them. 1 Lill. Abr. 477.

DISDIAPASON, or BISDIAPASON, in music, a compound concord, described by F. Parron, in the quadruple ratio of 4 : 1, or 8 : 2. The disdiapason is produced when the voice grows diatonically from its first to its fifteenth sound, and may be called a fifteenth. The voice ordinarily does not go farther than from its first sound to the disdiapason, that is, it does not go beyond the compound, or double octave; for the disdiapason is an octave doubled. The voice sometimes rises several degrees above the disdiapason, but the effort or struggle disfigures it, and makes it false. In reality, the ancient scale or diagram extended only to a disdiapason.

DISEASE, in medicine, that state of a living body, wherein it is deprived of the exercise of any of its functions, whether vital, natural, or animal. See MEDICINE.

DISEMBOGUE, in the sea-language, is said of a ship that passes out of a gulph or bay into the open sea. A river is also said to disembogue or discharge itself into the sea.

DISFRANCHISING, among civilians, signifies the depriving a person of the rights and privileges of a free citizen or subject.

DISFRANCHISEMENT, is the taking away a man's freedom or privilege. Corporations generally have power by their charter or prescription, to disfranchise a member for doing any thing against the duty of his office as citizen or burgess, and to the prejudice of the public weal of the city or borough, and against his oath, which he took when he was sworn a freeman. But the matter which shall be the cause of his disfranchisement, ought to be an act or deed, and not an endeavour or enterprize whereof he may repent before the execution thereof, and of which no prejudice ensues. 11 Co. 98.

DISH, among miners, denotes a wooden measure, wherein they are obliged to measure their ore; it is kept by the bar-master, and contains about 672 solid inches.

DISJUNCTIVE PROPOSITION, in logic, is that where of several predicates we affirm one necessarily to belong to the subject to the exclusion of all the rest, but leave that particular one undetermined. Such is the major of the following disjunctive syllogism.

The world is either self-existent, or the work of some finite, or of some infinite being:
But it is not self-existent, nor the work of a finite being;
Therefore it is the work of an infinite being.

DISLOCATION, the putting a bone out of joint by violence. See SURGERY.

DISMEMBERED, in heraldry, is applied to birds that have neither feet nor legs, and also to lions and other animals whose members are separated.

DISPARAGEMENT, in the law of England, is properly used for the matching an heir in marriage under his degree, or against decency.

DISPART, in gunnery, is the setting a mark upon the muzzle-ring, or thereabouts, of a piece of ordnance, so that a sight-line taken upon the top of the base-ring against the touch-hole, by the mark set on or near the muzzle, may be parallel to the axis of the concave cylinder. The common way of doing this, is to take the two diameters of the base-ring, and of the place where the dispart is to stand, and divide the difference between them into two equal parts, one of which will be the length of the dispart; which is set on the gun with wax or pitch, or fastened there with a piece of twine or marlin. By means of an instrument it may be done with all possible nicety.

DISPAUPER: when any person, on account of poverty, attested by his own oath of not being worth 5*l.* his debts being paid, is admitted to sue in forma pauperis, if afterwards, before the suit is ended, he has any

lands, or personal estate fallen to him; or that the court where the suit depends, thinks fit for that or any other reason, to take away that privilege from him; then he is said to be dispaupered, and can no longer sue in forma pauperis.

DISPENSARA, or DISPENSATORY, denotes a book containing the method of preparing the various kinds of medicines used in pharmacy. The apothecaries in and about London are obliged to make up their compound medicines according to the formulas prescribed in the college dispensary, and are enjoined to keep always ready in their shops all the medicines there enumerated.

It is also a kind of charitable institution supported by voluntary subscriptions; have each one or more physicians and surgeons, whose business it is to attend at stated times, in order to prescribe for the poor; and, if necessary, to visit them at their own habitations. It is in this latter respect, that the patients of a dispensary differ from those called out-patients at an hospital. The poor are supplied gratis with their medicines; and many of these institutions also afford gratuitous assistance to lying-in women.

DISPENSATION, in law, the granting a licence of doing some certain action that otherwise is not permitted. The greatest dealer in dispensations is the pope, who claims the office jure divino, and extends it to every thing. The more moderate of the Romanists themselves deny that he can give a dispensation for any thing contrary to the divine law, or the law of nature; and confine him to what is contrary to positive laws, or to things relating to fasts, marriages, holding several benefices, &c. and they limit him even in these things.

The Archbishop of Canterbury has a power, by statute, of dispensing in any cause wherein dispensations were formerly granted by the see of Rome, and as well to the king as his subjects; and during the vacancy of the archbishop's see, the guardian of the spiritualities may grant dispensations. Every bishop of common right has the power of instituting to benefices, and of dispensing in common cases, &c. A dispensation of the king makes a thing prohibited lawful to be done by the person that has it, though a thing evil in itself will not admit of a dispensation. And where the subject has an immediate interest in an act of parliament, the king cannot dispense with it; but may, if the suit be the king's own, only for the breach of a penal law that is not to the damage of a third person.

There is a dispensation by non obstante, which is where a statute tends to restrain some prerogative incident to the person of the king, as the right of pardoning, or commanding the service of the subjects for the benefit of the public, &c. each of which prerogatives is inseparable from the king, and therefore, by a clause non obstante, such a statute may be dispensed with.

DISPERSION. See SURGERY.

DISPLAYED, in heraldry, is understood of the position of an eagle, or any other bird, when it is erect, with its wings expanded or spread forth.

DISPONDEE, in the Greek and Latin poetry, a double spondee or foot, consisting of four long syllables.

DISPOSITION, in rhetoric, the placing of words in such an order as contributes most to the beauty, and sometimes even to the strength of a discourse.

DISSECTION. See ANATOMY. Le Gendre observes, that the dissection of a human body, even dead, was held a sacrilege till the time of Francis I. and the same author assures us he has seen a consultation held by the divines of Salamanca, at the request of Charles V. to settle the question whether or not it was lawful in point of conscience to dissect a human body, in order to learn the structure thereof.

It is easily perceived that surgery and physic must improve in a country, according to the opportunities of inquiring into the structure of the animal economy; for which reason we could wish that students in anatomy were furnished with subjects for dissection in this country, in as great abundance, and with as little inconvenience, as in France.

DISSEISIN, in law, is a wrongful putting out of him that is seized of the freehold, which may be effected either in corporeal inheritances, or incorporeal. Disseisin of things corporeal, as of houses and lands, must be by entry and actual dispossession of the freehold. Disseisin of incorporeal hereditaments, cannot be an actual dispossession, for the subject itself is neither capable of actual bodily possession nor dispossession, but is only at the election and choice of the party injured, if, for the sake of more easily trying the right, he is pleased to suppose himself disseised. And so also even in corporeal hereditaments, a man may frequently suppose himself to be disseised, when he is not so in fact, for the sake of entitling himself to the more easy and commodious remedy of an assise of novel disseisin, instead of being driven to the more tedious process of a writ of entry. 3 Black. 169.

DISSENTERS. Before the revolution many statutes were in force against dissenters, but by 1 W. stat 1. c. 18. commonly called the toleration act, it is enacted, that none of the acts made against persons dissenting from the church of England, (except the test acts 25 C. II. c. 2. and 30 C. II. st. 2. c. 1.) shall extend to any teacher or preacher dissenting from the church of England, who shall at the general sessions of the peace, to be held for the county or place where such person shall live, take the oaths of allegiance and supremacy, and subscribe the declaration against popery, of which the court shall keep a register; and no officer shall take more than 6*d*. for registering the same, and 6*d*. for a certificate thereof signed by such officer. Provided that the place of meeting be certified to the bishop of the diocese, or to the archdeacon of the archdeaconry, or to the justices of the peace at the general or quarter sessions; and the register or clerk of the peace shall register on record the same, and give certificate thereof to any one who shall demand the same, for which no greater fee than 6*d*. shall be taken; and provided that during the time of meeting, the doors shall not be locked, barred, or bolted. See CONVENTICLE. Dissenters chosen to any parochial or ward offices, and scrupling to take the oaths, may execute the office by deputy, who shall comply with the law in this behalf. 1 W. c. 18. But it seems they are not subject to fine, on refusing to serve corporation offices; for they may object to the va-

lidity of their election, on the ground of their own nonconformity. 3 Bro. P. C. 465.

DISSIDENTS, a denomination applied in Poland to persons of the Lutheran, Calvinistic, and Greek profession.

DISSIPATION, *circle of*, in optics, is used for that circular space upon the retina, which is taken up by one of the extreme pencils or rays issuing from an object. To understand this, it is to be observed, that when the distance of an object from the eye is too small or too great for perfect or distinct vision, the rays of each pencil, issuing from the object, cannot be united at a point on the retina, but beyond it, or before they arrive at the retina; consequently, the rays of each pencil will occupy a circular space upon the retina, and this circle is called the circle of dissipation, because the rays of a pencil, instead of being collected into a central point, are dissipated all over this circle. See Optics.

DISSOLVENT, in general, whatever dissolves or reduces a solid body into such minute parts as to be sustained in a fluid.

DISSOLUTION, in music, is when a sound in the enharmonic genus is lowered three dieses; for thereby that genus is dissolved, and the music, or that interval at least, is chromatic.

DISTAFF, an instrument about which flax is tied in order to be spun.

DISTANCE, in general, an interval between two things, either with regard to time or place. See Geometry and Mensuration.

Distance, in navigation, the number of minutes or leagues a ship has sailed from any given place or point. See Navigation.

Distance, in astronomy. The distance of the sun, planets, and comets, is found from their parallax, as it cannot be found either by eclipses or their different phases. For from the theory of the motions of the earth and planets we know, at any time, the proportion of the distances of the sun and planets from us; and the horizontal parallaxes are in a reciprocal proportion to these distances. See Astronomy.

Distance, *curtate*, the distance of the planet's place, reduced to the ecliptic, from the sun.

Distance *of the eye*, in perspective, is a line drawn from the eye to the principal point. See Perspective.

Distance *of the bastions*, in fortification, is the side of the exterior polygon.

DISTEMPER, in painting, a term used for the working up of colours with something besides water or oil. If the colours are prepared with water, that kind of painting is called limning; and if with oil, it is called painting in oil, and simply painting. If the colours are mixed with size, white of eggs, or any such proper glutinous or unctuous matter, and not with oil, then they say it is done in distemper. In this manner the admirable cartoons at Hampton-court are painted. The greatest disadvantage of distemper is, that it has no glittering, and all its colours look dead, by which means they appear alike in all sorts of lights, which oil colours, or even colours in distemper when varnished, do not.

DISTICH, a couplet of verses making a complete sense. Thus hexameter and pentameter verses are disposed in distichs.

DISTICHIASIS, in surgery, a disease of the eye-lids, when under the ordinary eyelashes there grows another extraordinary row of hair, which frequently eradicates the former, and pricking the membrane of the eye, excites pain, and brings on a defluxion.

DISTILLATION. The objects of distillation, considered as a trade distinct from the other branches of chemistry, are chiefly spirituous liquors, and those waters impregnated with the essential oils of plants, commonly called simple distilled waters. The distilling of compound spirits and waters is reckoned a different branch of business, and those who deal in that way are commonly called rectifiers. This difference, however, though it exists among commercial people, is not at all founded in the nature of the thing; compound spirits being made, and simple spirits being rectified, by the very same operations by which they are first distilled, or at least with very trifling alterations. See Chemistry.

The great object with every distiller ought to be, to procure a spirit perfectly flavourless, or at least as well freed from any particular flavour as may be; and in this country the procuring of such a spirit is no easy matter. The only materials for distillation that have been used in large quantity, are malt, and molasses or treacle. Both of these, especially the first, abound with an oily matter, which, rising along with the spirit, communicates a disagreeable flavour to it, and from which it can scarcely be freed afterwards by any means whatever.

Previous to the operation of distilling, those of brewing and fermentation are necessary. See Brewing. The fermentation ought always to be carried on as slowly as possible, and performed in vessels closely stopped, only having at the bung a valve pressed down by a spring, which will yield with less force than is sufficient to burst the vessel. It should even be suffered to remain till it has become perfectly fine and transparent; as by this means the spirit will not only be superior in quantity, but also in fragrance, pungency, and vinosity, to that otherwise produced.

With regard to performing the operation of distilling, there is only one general rule that can be given, namely, to let the heat in all cases be as gentle as possible. A waterbath, if sufficiently large, is preferable to any other mode, and will perform the operation with all the dispatch requisite for the most extensive business. As the end of rectification is to make the spirit clean as well as strong, or to deprive it of the essential oil as well as the aqueous part, it will be proper to have regard to this even in the first distillation. For this purpose, the spirit, as it first comes over, should be received into a quantity of cold water; as by this means the connection between it and the oily matter will be considerably lessened. For the same reason, after it has been once rectified in the water-bath, it should be again mixed with an equal quantity of water, and distilled a second time. Thus the spirit will be freed from most of the oily matter, even though it has been very much impregnated with it at first. After the spirit has been distilled once or twice in this manner from water,

it may be distilled in a water-bath without any addition; and this last rectification will free it from most of the water it contains.

For the distillation of compound spirits, the following practical rules will amply suffice, and will at the same time afford a competent view of the general process.

In rectifying and distilling compound goods, a smaller still is known to make a cleaner and better commodity than one that is larger: and one that is half a hogshead gage, over and above your hand breadth depth from the edge or top of your still, is accounted the fittest size for a moderate trade; both as it may be managed without fatigue, and as it produces encouraging profit much superior to the fund it requires. When you erect and place your still, and other utensils, let it be if possible in a building, outhouse, or shed, separate from, but nearly adjoining to, your dwelling-house or shop, to prevent any hazard which may arise by fire, to which all spiritous goods are liable; and no otherwise to be extinguished but with a woollen blanket or rug, drenched in water, and cast upon the flame, which extinguishes it by excluding the air. Let the work-house be large enough, not only in regard to your still, worm-tub, and pump, which must be all placed in a row, or ranged together, to contribute to your working with ease and pleasure, but because your spirits which are for distilling must lie in some proper place or part of your work-house, to be near at hand to charge your still with, and at some reasonable distance from the fire: and also that you may have room enough for placing all your empty vessels, tubs, cans, and other utensils properly belonging to the distilling-trade, to have them near at hand on all occasions; and let your still-house floor be paved with broad stones or flags, having a descent to carry off all the wash from your still, your hot liquor from the worm-tub, and other occasional slops, which will be made by washing your casks, &c. by which your still-house floor will always be kept clean. They are usually kept in a cistern underneath, and pumped up as wanted. It is absolutely necessary, that there be sufficiency of water where your pump is to be sunk, both to keep your worm-tub continually cool, to make up all your goods to their proper strength, and to serve all other occasions whatsoever; it matters not whether your water be soft or hard, if you have plenty of it.

Your still must be placed upon brick-work, having an ash-hole of 24 inches long, nine inches broad; and to the iron bars, where your fire is to be under your still, 21 or 22 inches high; made somewhat sloping, the better to command the ashes. When the brick-work is made about the height last-mentioned, you must place your grate-door (both of strong iron) before, or in the front of the stove, or place, where your fire is to be made under your still. The iron door and frame must be about ten inches long, and eight inches broad; close behind the door and frame must be placed two cross iron bars, about two inches and a half broad, half an inch thick, and 15 or 16 inches long; both ends of which bars must be laid about three inches into the brick-work, for fixing them the better; and the upper part of it must he about half an inch lower than the upper edge of the door-frames. Just behind the said two iron bars must be placed another flat iron bar, about an inch and a half broad, half an inch thick, and sixteen inches long, fastened in the brick-work as the former, and near an inch lower: upon which last-mentioned flat iron bar, your iron grate must rest at the higher end; and the other end of your iron grate must rest upon another flat iron bar of the same dimension, fastened at the furthest end, or most distant part of your still-bottom. The iron grate must consist of about eight bars of inch-square iron, but exactly of one length, made broad, or flatted diagonally, at each end, to rest on the two cross iron bars, so that the upper part of the square bars must be even with the higher part of the flat iron bars on which they rest, that the fire-shovel, or coal-rake, may run smoothly along them. The square iron bars must be about eighteen inches long, and laid loose within an inch breadth of each other upon the two broad iron bars, as firm as you can, yet so that they may be put in, or taken out, as occasion requires; then raise your brick-work, so that your still-bottom, when fixed or rested upon it, may be about 10 or 12 inches above the iron grate, that the fire may have room to play; and the part of the brick-work under the still, where the fire is placed, and as far as it extends within the stove, must be inlaid with hearth inch-tiles, or fire-brick, well fastened with such mortar as will abide the fire much longer than common bricks. Let not the fireplace be too broad, wherein your workman's judgment will have regard to the sides not being of the same thickness with the bottom of your still. There must be left a sloping place, or hole, proper for conveying the smoke into the flue and round the still into the chimney; which flue must be carried up a convenient height, to draw the smoke, and carry it off. Let your still-cock come so far through the brick-work, that your wash may run out either into cans, or otherwise, as you have conveniency for conveying it away. The brick-work about your still must be exactly round, as high as the upper nails of your still, sloping from the flame lest any liquor boil over, and very well mortared, and covered all round with coarse canvas or hop-sack, to keep the fire closer in, the wall from cracking, and your clothes from being injured, and the flue must be plastered well within.

Your worm-tub must be placed very near your still, upon a strong wooden frame according to the size of the tub, which must be six or eight times the capacity of your still, so that every stave of the tub may rest firmly upon the frame, the better to support the great weight of such a quantity of water as is necessary to keep the worm constantly cold, or cool enough. Your worm-tub frame must be so high, that when the tub is placed upon it, the low end of your worm which comes through the worm-tub, will admit of your cans being readily placed under, and taken away when they are full. The upper end of your worm must be placed so, that the arm of your still-head may go into it without any difficulty, and shut in so close as to be easily luted; and your worm-tub must stand so upright, that no liquor may hang in the worm, which you may know, by putting a pint or quart of water into the worm; which will run out at the lower end of it. In the middle of your worm-tub you may place a wooden gutter three or four inches square within, to reach from the top of the worm-tub to the bottom of the same, having about three or four inches on the opposite

sides at the bottom end of it left open, that the fluid that is pumped into the gutter, which descends, may flow out at the two breaches to the lower part of the worm-tub; which forces all the hot water to ascend upwards, and runs either over the worm-tub, or rather through a leaden pipe of a moderate size, which is called a waste pipe, being put through and soldered in your worm tub, and extended down your tub-sides to what further length you please, to convey the warm water from your tub, till the liquor in your worm-tub is perfectly cold; which by the continuance of your still working will grow hot again and again, and must be still cooled after the same manner. The water conveyed in by a lead pipe at the bottom is still better. Your pump must be placed next your worm-tub, and of such a height that you may have a spout or cock put into that part of your pump which is next your worm-tub, under which you may fix a good gutter, to reach to, and be led into, the gutter that is fixed in the middle of your worm-tub, that the liquor may be more easily, and with less waste, conveyed into your worm-tub, in order to cool it. You must have also another spout or cock in the fore-part of your pump, much lower than the other, for drawing water for all common uses; the higher spout being closed, and only appropriated for cooling the liquor when hot in the worm-tub. For the still, worm, &c. see Plate XLIII.

It will be necessary also to have a large back, set upon a strong frame, to command the worm-tub, and to contain a large quantity of water, having a large brass cock communicating with the still. &c. to draw off what water you may stand in need of suddenly; which may be of very great service to you upon any emergency; and may be drawn off in much less time, and with less trouble, than by pumping; for the still may accidentally be sometimes dry, and prove of dangerous consequences, if you had not a quantity of water ready on all occasions in your back to repair to. Your water-tub must be open at the upper end, that you may dip or drench your cans into it, or lay any small rundlets in it to steep and become tight; and that your tub may be more easily filled with water.

You will find your interest in keeping a good middle-sized press, placed in a corner of your still-house, and fixed so steadily as not to be moved when you use it; having a very strong bed or place, in which the goods to be pressed are put, and five or six hair-cloths, somewhat broader than your press, to be put betwixt every layer of elder-berries, cherries, raspberries, or any other things which are to be pressed; all which are to be laid as thin as possible, and your press-screw to be drawn pretty much, till the liquor run by a spout made of sheet-lead, nailed to the fore-part of the bottom of your press, into one of your cans, which must be placed under it, to receive the juice from the press, and draw out your iron-pin, to give time to the press to empty itself of what juice lies in the bed; then draw the screw a little closer, and allow time for the juice to run out, and so more and more, till all the juice is wholly drawn or pressed out of the goods. See Plate.

You must have also, at least, three or four iron-bound open-headed tubs, wide at the top, and narrower taperwise down to the bottom, (one of these tubs is to contain two puncheons or pipes of goods, another to contain one pipe, and another a hogshead) which must be placed orderly in your still-house, and now and then filled with hot liquor out of your still; and the iron hoops driven, or fastened, to keep them firm, and in fit condition to hold the goods that are to be put or made up in them. Likewise three or four iron-bound cans, either with iron round hands or bales; one to hold five, another to contain four, another three, and if you please, another two gallons; not by bare measure to the top, but let your goods reach no higher than a brass mark placed therein, determining the measure to which the liquor must rise. Another necessary utensil is an iron-bound wood funnel, which by computation would hold three or four gallons, with a strong iron nosel or pipe to put into the bungs of the casks which the goods are to be put in, which must be ranged or placed upon a shelf along with the iron-bound cans pretty near your still.

In some convenient part of your still-house, where room may be most spared, must be placed a pretty large vessel, either covered or open, with a cock in it, in which you must put all your feints or after-runnings, until you have a quantity worth your distilling over; into which vessel or cask you may put the washings out of your casks, the drippings of your cocks, any goods accidently spoiled, either by wrong mixture, spilling on the ground, or otherwise, or any thing else that has a spirituous matter or substance in it. Another piece of necessary furniture for your still-house, and which cannot be dispensed with, is a good strong copper or tin pump, of about five feet long, and six inches in circumference, its nosel about six inches from the top of the pump, and the nosel about fourteen inches long from the body of the pump; besides a little angular nosel about four inches, to be put on upon the other, or taken off as your occasions require. The use of this pump, with its appurtenances, is to draw off your spirits out of the pieces into your cans to charge your still with; and for many other similar purposes in which it will be serviceable.

A pewter-crane or siphon is also absolutely necessary, made somewhat semilunar, or like a half-moon or angle, about six feet and a half from one end to the other, and four inches round about on the outside, to draw goods out of any vessel where the pump cannot play. A pewter valencia is likewise useful, being about two feet long, tapering at the end, which you put into the piece, or any other vessel, to draw out any small quantity, by putting or moving your finger on the upper side of the valencia, whereby the liquor enters, for your tasting or trying its proof; which, with the crane, may be hung against the wall.

Hipocrate's bag, or flannel-sleeve, is another thing very necessary for the distiller, whereby all bottoms of casks, though ever so thick and feculent, by putting into this bag or sleeve to filtre, become presently clear, the porous parts of the bag being soon filled with the grosser matter; and the thin or liquid element running clear from the bag, and as good as any of the rest: also any foul goods or liquor may presently be made clear and fine, by putting some powdered alabaster into the goods or liquor, or sprinkling the same on the bag to stop up its pores, by which they presently become or run clear,

leaving nothing but the sediment or gross matter in the bag; nor do the goods or liquor contract the least ill flavour from the alabaster powder. This bag or sleeve is made of a yard or ell of flannel, not over-fine or close-wrought, laid sloping, so as to have the bottom of it very narrow, and the top as broad as the cloth will allow, well sewed up the side, and the upper part of the bag folded about a broad wooden hoop, and well fastened to it, then boring the hoop in three or four places, it may be suspended by a cord.

You must have for your still-fire a large poker, fire-shovel, and coal-rake, with other necessary utensils for your still-house; a cooper's hand-saw, adze, gimlet, a striking gimlet, a hammer, a pair of scratching-irons, a pair of tarriers, a bung-borer, a box-foreset, and a box of bungs.

When you are to distil, you are to make ready, against your still is charged, a paste of the size of a turkey-egg, made half of Spanish wheat, and the other half of rye-meal, bean-meal, or wheat-flour, well mixed together, and made into a paste with water, of the consistence of an ordinary paste for baking; and having put on your still-head, with its nose in the upper end of the worm, then take your paste, working and making it pliable with the heat and operation of your hands, and spread it upon the junctures of the body and head of your still, and that part of the arm of your still-head which goes into the end of the worm, to keep in the goods from boiling over: make the paste very smooth, by wetting your hand (with which you lay on the paste) in water, to cause it to lie the closer, and secure the goods from all mischances; and reserve a piece of paste, about the size of a small apple, lest the luting should crack or break out, which is very dangerous, and must therefore be carefully attended to and examined, and in case of any defect, mended with the paste reserved for that purpose.

When you set up a new still, which has not been used, let it be filled, within your hand-breadth of the brim, with water, and put to it a peck of wheat-bran; and put the head upon the still, and fix it firmly on with a wooden bar, about the thickness of your wrist, upon the loop, a little below the neck of your still, and the upper end of the wooden bar must be fastened under some beam or lentel perpendicularly, to prevent the still-head from moving by the force of distillation; then lute your still as directed in the foregoing paragraph; and having made a fire under it proper for that purpose, draw off two, three, or four gallon-cans by distillation, by which all the joints and nails of your still will be cemented, and made fit for distilling your strongest-proof goods; then damp or extinguish your fire with some wet ashes; wash your still-head and worm; afterwards you may charge and work your still with what goods you please.

All your spirits to be distilled should be proof goods, which you may try by having a small quantity put into a glass phial, and shaking it with your hand; if the blebs or proof of it continues a pretty while upon the top or surface of the goods, it is then what is called proof goods; and when it is distilled, it will yield about, or very near, two-third parts, or every thirty gallons will distil to nearly, and sometimes full, twenty gallons, according as the spirits are higher or lower proof; which you may make proof, or to what strength and weakness you please, by adding what proportion or quantity either of spring or river water is necessary; as for example, take and observe this general rule in distilling, that all double goods coming from the still, clear proof and without feints, must be made up with liquor, to that quantity you charged your still with at first; as if with thirty gallons o proof spirits, it will yield about twenty gallons of high-proof goods, the deficiency of ten gallons must be made up with water, till the whole amounts to thirty gallons, your first charge; and in single goods you add one and a half part more of water (viz. fifteen gallons) to what is ordered in double goods, whereby you will have in all forty-five gallons of single goods; but if your spirits are below proof, upon shaking the phial, or glass, the goods will fall flat, or the blebs or proof will not continue on the surface of it; and according to the degree of its being reduced more or less below proof, the goods will flatten accordingly; and when such good are distilled, they will fall short in quantity; and upon making them proof, and no otherwise, will you know what body they were of, and how far they were reduced, except by the hydrometer.

When your still is charged with goods for distilling, and luted, then make your fire under the still, which, if possible, must be of coals, because their heat is most constant and durable, and wood fires are very subject to both extremes, of too much or too little heat, which are prejudicial, and sometimes hazardous. Let the fire at first be moderate, and then by degrees increased, and now and then stirred up with your poker, as is usual in common fires; and by laying your hand upon the body of your still, as the fire gains strength in the stove or furnace under the still, you will by moderate degrees ascend up your still-head, occasioned by the goods in the still boiling higher and higher. When your still head becomes warm or hot, then prepare a damp (which is to check or lessen the violence of the fire); which damp is made of a about half a bushel of ashes, taken from under the stove or furnace, and two or three gallons of water cast upon and well mixed with them, upon the ground or hearth, before or under your kiln-door, to be ready to cast upon the fire when there is occasion; and move your hand upon the still, higher and higher, as you find the heat grow hotter, and ascend to the neck of your still-head, which, when it comes with any vehemence more than a common warmth, to turn downwards towards the worm-end, in which the arm of the still is luted, cast three or four fire-shovels of wet ashes upon the hottest part of the fire, which must be done very smartly and critically, at the very turning of the highest part of the swan-like neck of your still towards the still, by which the violence of the fire is abated, which would otherwise bring down the goods through the worm very foul in a rushing stream, which is dangerous, and by all means to be prevented; whereas your damping the fire seasonably, brings down the liquid like a small twine thread.

You must take especial care not to touch or meddle with your fire while your still is near coming to work, because of increasing or heightening the heat, which would unavoidably make your still run foul; but when your fire is damped and come to work, you may let your kiln-door be shut close, and continue so, as long as the worm runs as small as a moderate-large turkey quill.

But as the kiln-door being long shut will overcome the damp, and bring the fire to its former violence, so when you are apprehensive of it, you may throw open the kiln-door, which abates the heat immediately, and lessens the stream flowing from your worm; and you must cautiously meddle with your still-fire until more than one or two cans be come off from your still, which is about double the strength of the first goods, and then there is less danger, and you may more safely stir up or mend your fire, or shut your kiln-door, to make your goods come down with a little larger stream, until the goods be wholly come off from the still.

When you perceive near two-third parts of the first quantity which you put into your still to be run from thence, then be often tasting the goods, which must run as long as any strength remains; when all the goods are come off, the former clear colour of them will turn to a blue, and sometimes, according to the nature of the goods, a whitish colour, which are phlegmatic and foul, and if they were suffered to run amongst the spirit, would make it taste disagreeably, but by being kept by themselves, the goods are clean and well tasted; and the feints, or after runnings, being put and kept in a vessel until you have a quantity together, you may then distil them. When the strength of the spirit is gone, or run off, take away your can of goods, and let the feints run into another can, as long as the feints will burn on the still-head, being cast thereon, and a candle or lighted paper put to it to try the experiment.

When your feints are drawn into spirits, which must be made proof, that you may make a better judgment how to convert them to other goods, you must always make them into such goods as carry a very predominant or prevailing gust or taste, above other ingredients; and therefore the common and usual method taken with them is, to convert them into aniseed or wormwood cordials, putting a little more than the receipt of ingredients, which is made use of, the same goods being drawn from clean malt spirits, and also dulcifying a little higher than otherwise, purposely to cleanse or carry off any ill relish contracted from the multiplicity of mixtures in the feints.

You must always keep the water in the worm-tub, very cool, that the goods coming off the still may be perfectly so, which will contribute to bettering the spirits, and making them settle sooner; whereas the goods coming off warm or hot from the still, they loose considerable of their strength, which is extracted by the hot liquor, become more palatable, and not without much time and difficulty are made fine.

When you distil any goods which are not above one-third or one-half of the quantity your still will work, be sure you add one, two, or three cans of water to the goods you charge your still with, both for better preserving the still from damage, and because the goods will cleanse and fine themselves, by having a quantity of water with them wrought together, and will run considerably more from the still than when it is charged with full-proof goods; not that they can possibly be more in strength or substance, but by their being weakened with water put to them, are drawn lower, and require less fluid to make them proof.

When you draw off your still more than once a day, if your second distillation is of the same goods with the first, and the quantity of each the same, then when your goods and feints are drawn off, damp your fire very well under your still, draw the wash quite out, and, without cleaning out the ingredients, you may charge it a second time with the spirits and ingredients, and draw off your goods as at other times; but if you charge your still a second time with the same goods, and no greater quantity than what the goods run from what your still was first charged with, then, when your goods are come off and without suffering the feints to run, damp your fire, strike off your still-head, and charge your still accordingly with your ingredients, and draw them off as you do at other times; but if you charge your still a second time the same day with goods different from, and of another sort than, what your still was first charged with, then clean it of all the wash and ingredients, scrape off all the luting on the still-head and upper part of the body of your still, which remained or was left on the still-head; wash down the worm with about a gallon of liquor, to prevent all obstructions; and draw off your goods of the second charging or distillation, as you do at other times, the process not differing either in drawing off or making up the goods from what you do, when your still is charged with no other goods, or only one distillation made at that time.

Be sure that betwixt every new charging of your still you scrape off all the paste or luting which cleaves or is burned to the still-head, or the brim of your still, which might endanger your new luting to crack or break, was it put upon the old paste or luting; and also let your worm be constantly washed down with a gallon of water, lest any thing be accidentally got into the worm, which might prove of the worst consequence, and must therefore be prevented or guarded against by the greatest caution you can possibly take.

It conduces to meliorate compound spirits, when the ingredients of which they are made are infused in spirit over-night, before they are distilled; which spirit must cover the ingredients, and being measured, you must allow what they measured out of the quantity you put into your still, so that both the spirits in which the ingredients are infused, and the other which you measure into your still, must together make up the intended quantity; and let all your ingredients, according to their several kinds, be bruised, sliced, or otherwise separated, before their infusion, if you have time and opportunity.

Take particular care that no manner of grease, tallow, soap, or any other unctuous matter, get or fall into your pieces, tubs, rundlets, or cans; because they injure the proof of the goods, and although their strength should be very high, yet they will apparently fall as flat as water, and then their strength can only be ascertained by the hydrometer. Above all things, beware of lighted candles, torches, papers, or other combustible matter, being brought too near your still, or any vessel where your goods are contained, which are subject to take fire upon very slight occasions. You must take care to have your stove-chimney and flue often swept or cleaned; both to prevent the danger of its taking fire, and to make your flue, or kiln-chimney, draw the better, whereby your stove-fire will be first lighted, and afterwards continued, with less trouble.

It is best for preserving the strength and flavour of your goods, that as they come off your still into your cans, exactly filled up to the mark of a four or five gallon measure, they be emptied into the casks they are to be kept in; always noting, or keeping an account of, the several cans or quantity of goods to be put by; which must be made up to their several proportions, according to the quality or kind of goods so to be made up; which is, or must be, by adding so much liquor or pump-water, as completes the same. And in dulcifying your goods, first weigh the sugar you intend to put in; then dissolve it in one or more cans of the water, with which you make up your goods; bruising all the lumps of the sugar, and stirring it very well with a rummager in your cans, till all is dissolved: and then emptying it into your other goods; and mixing all well together, by drawing off several cans of the goods at the cocks, and putting them in again at the bungs; and then rummage all well together, till they are perfectly well mixed and compounded.

When you have made up your goods to the quantity and quality you intend, that they may become fine and clear, all your goods which are made proof will without any art or composition settle, and become fine and clear, within one or two days at most; but goods that are reduced below proof, the weaker they are made in strength, the longer they are in becoming fine or saleable. To every hogshead of Geneva, or strong waters, put five or six ounces of alum powdered so as to go through a coarse hair-sieve, and mixed in three or four gallons of the goods, well stirred or dissolved in your cans; and then put to your whole quantity, rummaged and very well stirred together, some cans of goods being drawn off, and put to the goods again, to mix them the better; and the Geneva will be clear in one day, and the other in two or three days.

When your distilled goods are finished, being set upon a stillyon or pair of guntress, in order to their being drawn off, you must let the bungs of the casks continue open, till they become fine and fit for use: then you may put the bungs in, but not too hard, and set a foreset or a plughole, and a foreset or plug put slightly, in a proper place of your casks, to take out or loosen, to give vent when you draw off any goods: it is a vulgar error to suppose that goods are materially injured or weakened by the bungs being left open; for where there is any quantity of goods of any tolerable body or strength, they receive no manner of injury from it, but mellow and clear more and more by having good vent either by bung or foreset.

You may make any goods deeper or lighter coloured, by dulcifying with browner or finer sugar. And as all common goods bear a low price, they are always sweetened with the cheapest brown sugars, which commonly make them of a deeper amber colour; which by long custom and usage has so prevailed with the populace, that goods of a lighter colour, occasioned by being dulcified with better sugar, are less accounted of; whereas fine goods, which are generally drunk by persons of judgment and distinguishing palates, must be made up with fine sugars; and the clearer and lighter colour they are, the more acceptable and valuable to those who know what they buy; and some persons are so nice this way, as to dulcify with loaf-sugar, but the sugars in your receipts specified are what will give a general satisfaction to all your customers.

When you first draw off any goods lately distilled, that which lies next the cork will not be clear, or left fine, according as the goods have been a longer or shorter time distilled; and must be set aside till you have drawn off what fine goods you have present occasion for; and then you may put what you first drew in at the bung, and it will settle in a very little time; and when any of your standard or other casks are near out, or to be emptied or drawn off, let all the bottoms be drawn into one of your cans, and first put one, two, or three gallons of water according to the size of your cask, to wash out the cask; and let your first water with which the cask is washed be put among your feints; and what water you wash clean out with must be cast away; then take your can of bottoms, and first hanging up your flannel sleeve in some convenient place, put your bottoms into it all at once, if your bag will hold it. The first runnings of the bag will be foul, till all the porous parts of the bag are filled up with the sediment that is amongst the bottoms of the casks; and when they run fine, you may take away the foul goods, and put a clean vessel to receive the fine spirits; and when the bag is run nearly out, you may put in it what goods first run foul when the bottoms were put into the bag, and let the bag hang till all the goods be quite run off from the sediment, which must then be cast away, but the fine goods, so filtred through the flannel sleeve, will be as good and wholesome as any of the rest; and the bottoms of fine goods, which are much more valuable, must be filtred, or put through blotting-paper, folded in four parts, one part or leaf to be opened funnelwise, and made capable to receive what it will hold of the bottoms being put into the upper part of a large tin funnel: which will filtre off all the goods from the sediment.

When you are to buy any brandies or spirits, do not consent to take them by measure; but having tasted and tried them in a phial, insist upon having them by weight, at seven pounds three quarters to each gallon, and the stronger spirits will be lighter than what is reduced.

It may not be here improper to insert some certain rules observed by distilleries in drawing off and making up their distilled goods: viz. when you perceive about two-third parts of the first quantity you put into your still is come off, then be often trying your goods in a glass or phial; and when you see that the bell, or proof, immediately falls down and does not continue a good while on the surface, then take away the can of goods, and substitute another vessel to receive the feints; which, if suffered to run among the goods, would cause a disagreeable relish, and be longer in fining down: whereas the feints being kept separate, the goods will be clean and well-tasted, when made up with liquor to their due quantity.

It will much improve your goods, to throw into your still along with your goods, when first charged, about six ounces of bay salt to every ten gallons of spirit; and so proportionally, more or less, to a greater or less quantity of spirits; by this means the goods will better cleanse themselves and separate from their phlegmatic parts, and the spirits so dephlegmated will ascend and come over much cleaner and finer in distillation.

One very great desideratum among distillers of this country is, a method of imitating the foreign spirits, brandy, rum, gin, &c. to a tolerable degree of perfection; and notwithstanding the many attempts that are daily made for this purpose, the success in general has been but very indifferent. The general method of distilling brandies in France differs in nothing from that practised here in working from malt-wash or molasses; nor are they in the least more cleanly or exact in the operation. They only observe more particularly to throw a little of the natural ley into the still along with the wine, as finding this gives their spirit the flavour for which it is generally admired abroad. But though brandy is extracted from wine, experience tells us, that there is a great difference in the grapes from which the wine is made. Every soil, every climate, every kind of grapes, varies with regard to the quantity and quality of the spirit extracted from them. A large quantity of brandy is distilled in France during the time of the vintage; for all those poor grapes that prove unfit for wine, are usually first gathered, pressed, their juice fermented, and directly distilled. This rids them of their poor wines at once, and leaves their casks empty for the reception of better. It is a general rule with them not to distil wine that will fetch any price as wine; for in this state the profits obtained are vastly greater than when reduced to brandies. The large stock of small wines, with which they are almost over-run in France, sufficiently accounts for their making such vast quantities of brandy in that country more than in others which lie in warm climates, and are much better adapted to the production of grapes. Nor is this the only source of their brandies; for all the wine that turns eager, is also condemned to the still: and, in short, all that they can neither export nor consume at home, which amounts to a large quantity; since much of the wine laid in for their family provision is so poor as not to keep during the time of drawing from the cask. Hence our English spirits, with proper management, are convertible into brandies that shall hardly be distinguished from the foreign in many respects, provided the operation is neatly performed.

The best, and indeed the only method of imitating French brandies to perfection, is by an essential oil of wine; this being the very thing that gives the French brandies their flavour. It must, however, be remembered, that in order to use even this ingredient to advantage, a pure tasteless spirit must first be procured; for it is ridiculous to expect that this essential oil should be able to give the agreeable flavour of French brandies to our malt spirit, already loaded with its own oil, or strongly impregnated with a lixivious taste from the alkaline salts used in rectification.

To prepare the oil of wine, take some cakes of dry wine-lees, such as are used by our hatters, dissolve them in 6 or 8 times their weight of water, distil the liquor with a slow fire, and separate the oil with a separating glass, reserving for only the nicest uses that which comes over first, the succeeding oil being coarser and more resinous. Having procured this fine oil of wine, it may be dissolved in alcohol; by which means it may be preserved a long time fully possessed of all its flavour, but otherwise it will soon grow rancid.

With a fine essential oil of wine thus procured, and a pure and insipid spirit, French brandies may be imitated to perfection. The essential oil, however, must be drawn from the same kind of lees as the brandy to be imitated was procured from; *e.g.* in order to imitate Coniac brandy, it will be necessary to distil the essential oil from Coniac lees; and the same for any other kind of brandy. For as different brandies have different flavours, and as these flavours are entirely owing to the essential oil of the grape, it would be preposterous to endeavour to imitate the flavour of Coniac brandy with an essential oil procured from the lees of Bourdeaux wine. When the flavour of the brandy is well imitated by a proper dose of the essential oil, and the whole reduced into one simple and homogeneous fluid, other difficulties are still behind: the flavour, though the essential part, is not, however, the only one; the colour, the proof, and the softness, must also be regarded, before a spirit that perfectly resembles brandy can be procured. With regard to the proof, it may be easily accomplished, by using a spirit rectified above proof; which, after being intimately mixed with the essential oil of wine, may be let down to a proper standard with fair water: and the softness may, in a great measure, be obtained by distilling and rectifying the spirit with a gentle fire; and what is wanting of this criterion in the liquor when first made, will be supplied by time: for it must be remembered, that it is time alone that gives this property to French brandies, they being at first acrid, foul, and fiery. But with regard to the colour, a particular method is required to imitate it to perfection, which may be effected by means of treacle or burnt sugar. The treacle gives the spirit a fine colour, nearly resembling that of French brandy; but as its colour is dilute, a large quantity must be used. This is not, however, attended with any bad consequences; for notwithstanding the spirit is really weakened by this addition, yet the bubble-proof, the general criterion of spirits; is greatly mended by the tenacity imparted to the liquor by the treacle. The spirit also acquires from the mixture a sweetish or luscious taste, and a fulness in the mouth; both which properties render it very agreeable to some palates. A much smaller quantity of burnt sugar than of treacle will be sufficient for colouring the same quantity of spirits: the taste is also very different; for, instead of the sweetness imparted by the treacle, the spirit acquires from the burnt sugar an agreeable bitterness, and by that means recommends itself to many who are offended with a luscious spirit. The burnt sugar is prepared by dissolving a proper quantity of sugar in a little water, and scorching it over the fire till it acquires a black colour. Either treacle or burnt sugar will nearly imitate the genuine colour of old French brandy; but neither of them will succeed when put to the test of the vitriolic solution.

The spirit distilled from molasses or treacle is very pure. It is made from common treacle dissolved in water, and fermented in the same manner as the wash for the common malt spirit. But if some particular art is not used in distilling this spirit, it will not prove so vinous as malt spirit, but more flat and less pungent and acid, though otherwise much cleaner-tasted, as its essential oil is of a much less offensive flavour. Therefore, if good fresh wine-lees, abounding in tartar, are well fermented with molasses, the spirit will acquire a much

greater vinosity and briskness, and approach much nearer to the nature of foreign spirits. Where the molasses spirit is brought to the common proof-strength, if it is found not to have a sufficient vinosity, it will be very proper to add some dulcified spirit of nitric; and if the spirit is clean worked, it may, by this addition only, be made to pass on ordinary judges for French brandy. Great quantities of this spirit are used in adulterating foreign brandy, rum, and arrack. Much of it is also used alone in making cherry-brandy and other cordials by infusion; in all which, many, and perhaps with justice, prefer it to foreign brandies. Molasses, like all other spirits, is entirely colourless when first extracted; but distilleries always give it as early as possible the colour of foreign spirits.

If these principles hold good, the imitation of foreign spirits of all kinds must be practicable; if we only procure some of those substances from which the spirit is drawn, and distil it with water, the essential oil will always give the flavour desired. Thus to imitate Jamaica rum, it will only be necessary to procure some of the tops, or other useless parts, of the sugar-canes, from which an essential oil being drawn, and mixed with clean molasses spirit, will give it the true flavour. The principal difficulty must lie in procuring a spirit totally, or nearly, free from all flavour of its own. The spirit drawn from the refuse of a sugar-house has been commended, as superior to that drawn from molasses; though it is very probable, that to procure an absolutely flavourles spirit is impossible. The only method, therefore, of imitating foreign spirits is, by choosing such materials as will yield a spirit flavoured as much like them as possible; and the materials most recommended, and probably the best that can be used, are raisins.

We shall subjoin the genuine process of preparing Holland gin, agreeably to the practice of the Dutch distillers. Their grist is composed of ten quarters of malt, ground considerably finer than our malt-distillers' barley grist, and three quarters of rye-meal: or more frequently, of ten quarters of rye and three quarters of malt-meal. The ten quarters are first mashed with the least quantity of cold water it is possible to blend it up with; when uniformly incorporated, as much boiling water is added as forms it into a thin batter; it is then put into one, two or more casks, or gyle-tuns, with a much less quantity of yeast than is usually employed by our distillers. Generally on the third day they add the malt or rye-meal, previously made into a kind of lob, prepared in a similar manner, except in not being so diluted; but not before it comes to the temperature of the fermenting wash; at the same time adding full as much yeast as when at first setting the backs.

The principal secret in the management of the mashing part of the business is, in first thoroughly mixing the malt with the cold water, and in subsequently adding the due proportion of boiling water, that it may still remain sufficiently diluted after the addition of the fine meal, under the form of lob, and in well rousing all together in the back, that the wash may yet be dilute enough for distilling, without endangering its burning to the bottom of the still. Thus they commodiously reduce the business of brewing and fermenting to one operation. By using cold water to uniformly wet the malt, all danger of clogging the spending of the tap would be necessarily avoided; but here is no occasion to do any thing more than sufficiently dilute the wash, consisting of the whole of the grain, thin enough to be fermented and distilled together, by which means the spirit of the bran and husky part, as well as of the flour of the grain, are completely extracted, yet their wash, compared with ours, is about three-eighths thinner. For these reasons, they obtain more spirit from their grain than we do, and of a better quality, with not half the trouble taken by our distillers. The gravity of the distillers' wash at Weesoppe, in the neighbourhood of Amsterdam, in 1774, was but eighteen pounds per barrel, very little more than half the gravity of ours. Their stills are usually from three to five hundred gallons each; they constantly draw off three cans of phlegm, after the runnings cease to burn on the head of the still, when distilling wash; and five cans when distilling low wines, a practice we are unacquainted with; as we usually draw our fire as soon as the runnings from the still burn languidly on the still-head. This, and the great quantity of rye they use, cause their spirit to be so much more acid; and the diluteness of their wash is a very good reason for the greater purity of their spirit; though most writers mistakingly say, our spirit is much cleaner.

Rectification into Holland gin. To every twenty gallons of spirit of the second extraction, about the strength of proof spirit, take three pounds of juniper-berries, and two ounces of oil of juniper, and distil with a slow fire until the feints begin to rise, then change the receiving can; this produces the best Rotterdam gin. An inferior kind is made with a still less proportion of berries, sweet fennel-seeds, and Strasburgh turpentine, without a drop of juniper-oil. It, and a better sort, but inferior to the Rotterdam gin, are made at Weesoppe. The distillers' wash at Scheedam and Rotterdam is still lighter than at Weesoppe, where there were about three hundred distillers formerly in 1774. In Plate XLIII. Miscel. fig. 49, is the representation of a common still. It is a large copper vessel, A. into which the materials are put. The still is built up in brickwork: the fire is applied underneath, and runs round it in a spiral manner. B is the head of the still, which is connected with the worm at c. The worm C is a spiral tube, immersed in a vessel of cold water, called the refrigeratory. The liquor being condensed in its passage through the worm, runs out at the cock D into the vessel Z, placed there to receive it.

DISTILLER, he who makes distillations, and commonly a tradesman who makes spirits from malt, &c. By stat. 3 Geo. III. c. 5, s. 12, persons who sell liquors chargeable with duty, and distil spirits, are deemed common distillers, and are liable to surveys, penalties, &c. See EXCISE.

DISTINCTION, in logic, is an assemblage of two or more words, whereby disparate things, or their conceptions, are denoted.

There are three kinds of distinctions, taken from the three different modes of existence, real, modal, and rational. The first is that between two substances, or the modes of two substances. The second, or modal distinction, is that between several things, one whereof may exist without the other, but not vice versa, the other without that. The third, or rational distinction, is that

between several things which are really one and the same, and whereof one cannot exist without the other; nor vice versa, the other without this: such is that between a thing and its essence, between the essences and properties, &c. Of this distinction some authors admit two kinds: the one barbarously called rationis ratiocinatæ, having some foundation in things, as when we distinguish the justice of God from his mercy; the other called rationis raticionantis, which has no foundation at all, and therefore is by many rejected. Chauvin.

DISTORTION, in medicine, a contraction of one side of the mouth, occasioned by a convulsion of the muscles of one side of the face: and it is likewise used to denote any part of an animal body when it is ill placed.

DISTRESS, in law, the taking of a personal chattel, out of the possession of the wrong-doer, into the custody of the person who is injured, to procure a satisfaction for the wrong committed. It is of two kinds; cattle for trespassing, for doing damage; or for nonpayment of rent or other duties. But the most usual injury for which a distress may be taken is that of nonpayment of rent.

A distress may now be taken for any kind of rent in arrear, the detaining of which beyond the day of payment, is an injury to him that is entitled to receive it. 4 G. II. c. 28. This is the most common and best remedy for the recovery of rent in arrear; and the effect of it is to compel the party to replevy the distress, and contest the taking in an action against the distrainer; or, which is more usual, to compound or pay the debt or duty for which he was distrained. 3 Black. 6.

Distress infinite, is a process commanding the sheriff to distrain a person from time to time, and continually afterwards, by taking his goods, by way of pledge, to enforce the performance of something due from the party distrained upon. Generally, it is provided that distress shall be reasonable and moderate; but in case of distress for suit of court, or for defect of appearance, in several cases where this is the only method of enforcing compliance, no distress can be immoderate; because, be it of what value it will, it cannot be sold, but shall be immediately restored on satisfaction made. 3 Black. 251.

Who may distrain for rent. By the common law, and the various statutes in favour of this species of remedy for recovery of rent, all persons having the reversion or remainder of lands, &c. after the determination of the particular estate, or existing term therein, may of common right distrain for rent in arrear, without any clause for that purpose contained in the lease. Co. Lit. 142.

What may or may not be distrained. Every thing upon the premises is liable to the landlord's distress for rent, whether they are the effects of a tenant or a stranger, because of the lien the landlord has on them in respect of the place where the goods are found, and not in respect of the person to whom they belong. Co. Lit. 47. 3 Bur. 1502. 3 Durnf. and East, 601.

Things not distrainable are, tools of a man's trade, corn sent to a mill, a horse sent to a smith's shop or in a common inn, cloth at a taylor's, goods in the hands of a carrier. 1 Salk. 249. 1 Esp. Rep. 206. 4 T. R. 569. Dogs, rabbits, beasts of the plough, milk, fruit, and things fixed to the freehold. 3 Black. 8 and 9. 4 T. R. 569. But beasts of the plough, and working-tools, not actually in use at the time, may be distrained, if there is not sufficient without them. 4 T. R. 569. So may wearing apparel not actually in use. 1 Esp. Rep. 206. Money in a bag sealed may be distrained.

Horses and carriages sent to stand at livery are distrainable by the landlord. 3 Bur. 1498.

Of the time, &c. and manner of taking the distress. Distress for rent must be in the day-time, for if made at night it will be bad. Co. Lit. 142.

Strictly, the rent is demandable, and payable, before the time of sunset of the day when it is reserved. Yet the rent is not due till the last minute of the natural day. 2 Black. 42.

Distress cannot be made therefore till the day after that on which the rent is reserved in the lease; for though payable, it is not strictly due till midnight of the day upon which it is reserved.

Distress cannot be made after the rent has been tendered: if the landlord comes to distrain, the tenant may, before the distress made, tender the arrears: and if the distress is afterwards taken it is illegal; and so if after the distress, and before it is impounded, the tenant tenders payment, the landlord will deliver up the distress; and if he do not, the detainer is unlawful. 2 Inst. 107.

Parole authority to distrain is sufficient, or any authority that can be proved.

By 2 G. II. c. 19, landlords may, by the assistance of a peace-officer of the parish, break open in the day-time any place where goods are fraudulently removed and locked up to prevent a distress, oath being first made, in case it be a dwelling-house, of a reasonable ground to suspect that such goods are concealed therein.

By stat. 8 Anne, c. 14, rent accruing due under a lease must be distrained for within six months after its determination.

If a tenant fraudulently remove goods off the premises, the landlord may seize them within thirty days. But such seizure can only be made where the rent was actually due before the removal.

If a landlord seize only a part of the goods, &c. of his tenant for rent, in the name of them all, it will be a good seizure of the whole. 6 Mod. 215.

Distresses ought not to be excessive, but in proportion to the duty distrained for. 2 Inst. 106.

The remedy for excessive distress is by a special action on the stat. of Mulbridge; for an action is not maintainable upon this account, this being no injury at common law. 1 Vent. 104. Fitzgib. 85. 4 Bur. 590.

Where any distress shall be made for rent justly due, and any irregularity or unlawful act shall be afterwards committed by the party distraining, or his agents, the distress itself shall not on that account be deemed unlawful, nor the party a trespasser from the first; but the person aggrieved shall recover full satisfaction for the special damage sustained by such irregularity, and no more, with full costs of suit. 11 G. II. c. 19.

How a distress is to be disposed of. Persons distraining for rent may impound the distress upon any convenient part of the land, chargeable with the distress; otherwise the goods must be removed to a pound covert, and notice given where they are, unless the tenant consent to a person remaining in possession on the premises. Wood's Inst. 191.

All living chattels distrained are regularly not to be put in the pound covert, because the owner at his peril is to sustain them; and therefore they ought to be put in such an open place as that he may have resort to them for that purpose. Co. Lit. 47. b.

Household goods, and such other things as would be damaged by the weather, must be impounded in the pound covert; otherwise if they are damaged the distrainer will be answerable for the loss. 1 Inst. 47.

If the distress for rent dies or is damaged in the pound, without any default of the distrainer, he may make a fresh distress. 1 Salk. 348.

By 2 W. and M. it is provided, that where any goods or chattels shall be distrained for rent due on any demise, lease, or contract whatsoever, and the owner shall not, within five days next after such distress taken, and notice thereof, and of the cause of the taking left at the dwelling-house, or other most notorious place on the premises charged with the rent, replevy the same, that then, at the expiration of the said five days, the distrainer may, with the assistance of the sheriff, under-sheriff, or constable, cause the goods and chattels so distrained to be appraised by two sworn appraisers, and sold for the best price that can be got for the same, towards satisfaction of the rent for which the said goods and chattels have been distrained, and the costs and charges of such distress, appraisement, and sale; leaving the overplus (if any) in the hands of the said sheriff, or constable, for the use of the owner.

By stat. 2 W. c. 5, on any pound-breach or rescous of goods distrained for rent, the persons grieved thereby shall, in a special action on the case, recover treble damages and costs against the offender, or against the owner of the goods, if they are afterwards found to have come to his use or possession.

Distress for penalties. By 27 G. II. c. 20, s. 1, in all cases where any justice of the peace shall be required or empowered by any act of parliament to issue a warrant of distress for the levying any penalty inflicted, or any sum of money directed to be paid by such act, it shall be lawful for the justice granting such warrant, therein to order and direct the goods and chattels so to be distrained, to be sold and disposed of within a certain time to be limited in such warrant; so as such time be not less than four days, nor more than eight days; unless the penalty, or sum of money for which the distress shall be made, together with the reasonable charges of taking and keeping such distress, shall be sooner paid.

Distress of the king. By the common law no subject can distrain out of his fee or seigniory, unless cattle are driven to a place out of the fee, to hinder the lord's distress, &c. But the king may distrain for rentservice, or fee-farm in all the lands of the tenant, wheresoever they be; not only on lands held of himself, but others, where his tenant is in actual possession, and the land manured with his own beasts. 2 Inst. 132.

DISTRIBUTION of intestate's effects, after payment of the debts of the deceased, is to be made according to the stat. 22 and 23 G. II. c. 10, in manner following. One-third shall go to the widow of the intestate, and the residue in equal proportions to his children; or if dead to their representatives, that is, their lineal descendants: if there are no children or legal representatives, then a moiety shall go to the widow, and a moiety to the next kindred in equal degree, or their representatives; if no widow, the whole shall go to the children; if neither widow nor child, the whole shall be distributed amongst the next kindred in equal degree, and their representatives: but no representatives are admitted among collaterals, farther than the children of the intestate's brothers and sisters. The father succeeds to the whole personal effects of his children, if they die intestate, and without issue; but if the father be dead, and the mother survive, she shall only come in for a share equally with each of the remaining children.

Distribution, in logic, is a kind of division which distinguishes an universal whole into its several kinds or species; as division is to distinguish an integral whole into its several parts.

Distribution, in printing, the taking a form asunder, separating the letters, and disposing them in the cases again, each in its proper box.

DISTRICT, in geography, a part of a province, distinguished by peculiar magistrates, or certain privileges. in which sense it is synonymous with hundred.

DISTRINGAS, in law, a writ commanding the sheriff, or other officer, that he distrain a person for debt to the king, &c. or for his appearance at a certain day. There is a great diversity of this writ.

Distringas juratores, a writ directed to the sheriff, whereby he is commanded to distrain upon a jury to appear, and to return issues on their lands, &c. for non-appearance. This writ of distringas juratores issues for the sheriff to have their bodies in court, &c. at the return of the writ.

DITCH, in fortification, the same with moat. See Fortification.

DITHYRAMBUS, in ancient poetry, a hymn in honour of Bacchus, full of transport and poetical rage. This poetry owes its birth to Greece, and to the transports of wine; and yet art is not quite exploded, but delicately applied to guide and restrain the dithyrambic impetuosity, which is indulged only in pleasing flights. Horace and Aristotle tell us, that the ancients gave the name of dithyrambus to those verses in which none of the common rules or measures were observed. As we have now no remains of the dithyrambus of the ancients, we cannot say exactly what their measure was.

DITONE, in music, an interval comprehending two tones. The proportion of the sounds that form the ditone is 4 : 5, and that of the semiditone is 5 : 6. F. Parran makes the ditone the fourth kind of simple concord, as comprehending two tones, according to Aristotle, a greater and a less. Others make it the first discord, dividing the ditone into eighteen equal parts, or commas; the nine on the acute side making the greater tone, as asserted by Salmon de Caux.

DIVAN, a council-chamber, or court of justice, among the eastern nations, particularly the Turks. The word is Arabic, and signifies the same with sopha in the Turkish dialect. There are two sorts of divans; that of the grand-signior, called the council of state, which consists of seven of the principal officers of the empire; and that of the grand-vizir, composed of six other vizirs and counsellors of state, the chancellors, and secretaries of state, for the distribution of justice. The word is also

used a for hall in the private houses of the orientals. The custom of China does not allow the receiving of visits in the inner parts of the house, but only at the entry, in a divan contrived on purpose for ceremonies. Travellers relate wonders of the silence and energy of the divans of the East.

Divan-beghi, the superintendant of justice in Persia, whose place is the last of the six ministers of the second rank, who are all under the athemadauler, or first minister. To this tribunal of the divan-beghi he appeals from sentences passed by the governors: he has a fixed stipend of 50,000 crowns for administering justice: all the serjeants, ushers, &c. of the court are in his service: he takes cognizance of the criminal causes of the chams, governors, and other great lords of Persia, when accused of any fault. There are divan-beghis not only at court, and in the capital, but also in the provinces, and other cities of the empire. The alcoran is the sole rule of his administration of justice, which also he interprets at pleasure. He takes no cognizance of civil causes; but all differences arising between the officers of the king's household, and between foreign ministers, are determined by him.

DIVER, in ornithology. See Colymbus.

DIVERGENT or *diverging lines*, in geometry, are those which constantly recede from each other.

Divergent rays, in optics, are those which going from a point of the visible object, are dispersed, and continually depart one from another, in proportion as they are removed from the object: in which sense it is opposed to convergent. See Optics.

DIVERSION, in military affairs, is when an enemy is attacked in one place where they are weak and unprovided, in order to draw off their forces from another place, where they have made, or intend to make, an irruption. Thus the Romans had no other way in their power of driving Hannibal out of Italy, than by making a diversion in attacking Carthage.

DIVERSITY, in logic, stands in opposition to identity. See Identity.

Diversity, in painting, consists in giving every part or figure in a piece its proper air and attitude. See Painting.

DIVESTING, or *divestiture*, in law, is used for the act of surrendering one's effects. By a contract of donation, or sale, the donor, or seller, is said to be disseised and divested of his property in such a commodity. In this sense it stands contradistinguished from investiture, where the donee or purchaser becomes invested with the property of the donor or seller.

DIVIDEND, in arithmetic, the number proposed to be divided into equal parts. It must always be greater than the divisor. See Arithmetic.

Dividend, in the Exchequer, is one part of an indenture.

Dividend *of stocks*, is a share or proportion of the interest of stocks erected on public funds, as the South Sea, &c. divided among, and paid to, the proprietors half-yearly. See Stocks.

Dividend, in the university, signifies that part or share which the fellows equally divide among themselves of their yearly stipend.

DIVING, the art or act of descending under water to considerable depths, and abiding there a competent time. The uses of diving are very considerable, particularly in the fishing for pearls, corals, sponges, &c. See Pearl-fishing, &c.

Various methods have been proposed, and engines contrived, to render the business of diving more safe and easy. The great point in all these is to furnish the diver with fresh air, without which he must either make but a short stay, or perish.

Those who dive for sponges in the Mediterranean, help themselves by carrying down sponges dipt in oil in their mouths. But considering the small quantity of air that can be contained in the pores of a sponge, and how much that little will be contracted by the pressure of the incumbent water, such a supply cannot long subsist the diver. For it is found by experiment that a gallon of air included in a bladder, and by a pipe reciprocally inspired and expired by the lungs, becomes unfit for respiration in little more than one minute of time. For though its elasticity is but little altered in passing the lungs, yet it looses its oxygen, and is rendered effete. In effect, a naked diver, Dr. Halley assures us, without a sponge, cannot remain above two minutes inclosed in water; nor much longer with one without suffocating; nor without long practice near so long, ordinary persons beginning to be suffocated in about half a minute. Besides, if the depth is considerable, the pressure of the water on the vessels makes the eyes bloodshotten, and frequently occasions a spitting of blood. Hence where there has been occasion to continue long at the bottom, some have contrived double flexible pipes, to circulate air down into a cavity inclosing the diver, as with armour, both to furnish air, and to bear off the pressure of the water, and give leave to his breast to dilate upon inspiration: the fresh air being forced down one of the pipes with bellows, and returning by the other, not unlike to an artery and vein.

But this method is impracticable when the depth surpasses three fathoms; the water embracing the bare limbs so closely as to obstruct the circulation of the blood in them; and also pressing so strongly on all the junctures where the armour is made tight with leather, that, if there is the least defect in any of them, the water rushes in, and instantly fills the whole engine, to the great danger of the diver's life.

It is said to be a fact, that people, by being accustomed to the water from their infancy, will at length be enabled, not only to stay much longer under water than could be supposed, but put on a kind of amphibious nature, so that they seem to have the use of all their faculties as well when their bodies are immersed in water as when they are on dry land. Most savage nations are remarkable for this. According to the accounts of our late voyagers, the inhabitants of the South Sea islands are such expert divers, that when a nail or any piece of iron was thrown overboard, they would instantly jump into the sea after it, and never fail to recover it, notwithstanding the quick descent of the metal. Even among civilized nations many peasons have been found capable of continuing an incredible length of time under water. The most remarkble instance of this kind is the famous Sicilian diver, Nicolo Pesce, who according to the marvellous, and indeed incredible account given by

Kircher, had from his infancy been so used to the sea, that at last it became almost his natural element. It is said he was frequently known to spend five days in the waves without any other provisions than the fish which he caught there, and ate raw. He often swam over from Sicily into Calabria, a tempestuous and dangerous passage, carrying letters from the king; and as frequently swam among the gulphs of the Lipari islands, no way apprehensive of danger. "In order," says Kircher, "to aid these powers of enduring in the deep, nature seemed to have assisted him in a very extraordinary manner: for the spaces between his fingers and toes were webbed, as in a goose; and his chest became so very capacious, that he could take in, at one inspiration, as much breath as would serve him for a *whole day*." At length, however, we are told, this extraordinary person met his fate in exploring the depths of Charybdis, at the instance of the king; who, after he had once succeeded in bringing up a golden cup that had been thrown in, ordered him to repeat the experiment.

To obviate the inconveniences of diving to those who have not the extraordinary powers attributed to Nicholas Pesce, different instruments have been contrived. The chief of these is the diving-bell; which is most conveniently made in form of a truncated cone, the smaller base being closed, and the larger open. It is to be poised with lead; and so suspended, that the vessel may sink full of air, with its open basis downward, and as nearly as may be in a situation parallel to the horizon, so as to close with the surface of the water all at once. The diver sitting under this, sinks down with the included air to the depth desired; and if the cavity of the vessel can contain a tun of water, a single man may remain a full hour, without much inconvenience, at five or six fathoms deep. But the lower he goes, the included air contracts itself according to the weight of the water which compresses it; so that at thirty-three feet deep the bell becomes half full of water, the pressure of the incumbent water being then equal to that of the atmosphere; and at all other depths the space occupied by the compressed air in the upper part of the bell will be to the under part of its capacity filled with water, as thirty-three feet, to the surface of the water in the bell below the common surface. And this condensed air being taken in with the breath soon accommodates itself to the existing circumstances so as to have no ill effect, provided the bell is permitted to descend slowly. But the greatest inconvenience of this engine is, that the water entering it contracts the bulk of air into so small a compass, that it soon heats, and becomes unfit for respiration: so that there is a necessity for its being drawn up to recruit it; besides the uncomfortable situation of the diver, who must be almost covered with water.

To obviate these difficulties of the diving-bell, Dr. Halley, to whom we owe the preceding account, contrived a farther apparatus, whereby not only to recruit the air from time to time, but also to keep the water wholly out of the machine at any depth. This bell was made of wood, containing about sixty cubic feet in its concavity; and was of the form of a truncated cone, whose diameter at the top was three feet, and at the bottom five. It was so loaded with lead, that it would go down in a perpendicular direction, and no other. In the top was a window to let in light, and likewise a cock to let out the hot air that had been breathed; and below, about a yard under the bell, was a stage, suspended by three ropes, each of which was charged with about one hundred-weight to keep it steady. To supply air the bell had a couple of barrels, so cased with lead as to sink when empty; each having a bunghole in its lowest part to let in the water, as the air in them condensed on their descent, and to let it out again when they were drawn up full from below. To a hole in the uppermost part of these was fixed a leathern trunk or hose, long enough to fall below the bunghole, and kept down by a weight in such a way that the air in the upper part of the barrels could not escape, unless the lower ends of these hose were first lifted up. These air-barrels were made to rise and fall like two buckets in a well. By means of these barrels fresh air was continually supplied from above; and it was done with so much ease, that two men, with less than half their strength, could perform all the labour required. By an additional contrivance it was found practicable for a diver to go out of the engine to some distance from it, the air being conveyed to him in a continued stream by small flexible pipes. Some idea of Dr. Halley's machine may be formed from the inspection of Plate XLIV. Miscel. fig. 50. where the divers are seen at work. B, L, K, R, I, M, P, represent the body of the bell. B, the glass which serves as a window. H, the cock for letting out the air which has been breathed. L, M, the seats. C, one of the air-barrels. P, Q, two of the divers. F, another diver at a distance from the bell, and breathing through the flexible tube K. This diver is supposed to have a head-piece of lead, made to sit quite close about his shoulders: this head-piece is capable of containing as much air as will supply him for a minute or two. When he had occasion for more air he turned a cock at F, by which means a communication was opened with the air in the bell, and thus he could receive a new supply at pleasure.

Since the invention of the diving-bell there has been one contrived by Mr. Triewald, military architect to the king of Sweden, which, for a single person, is in some respects thought to be more eligible than Dr. Halley's, and is constructed as follows; AB, Plate XLIV. Miscel. fig. 51, is the bell, which is sunk by leaden weights D D, hung to its bottom. This bell is of copper, and tinned all over on the inside, which is illuminated by strong convex lenses, G, G, G, with copper lids H, H, H, to defend them. The iron ring or plate, E, serves the diver to stand on when he is at work; and is suspended at such a distance from the bottom of the bell by the chains F, F, F, that when the diver stands upright his head is just above the water in the bell, where the air is much better than higher up, because it is colder, and consequently more fit for respiration. But as the diver must always be within the bell, and his head of course in the upper part, the inventor has contrived that, even there, when he has breathed the hot air as well as he can, he may, by means of a spiral copper tube *b* C, placed close to the inside of the bell, draw the cooler and fresher air from the lowermost parts: for which purpose a flexible leather tube, about two feet long, is fixed to the upper end of the copper tube at *b*; and to the other end of this

tube is fixed an ivory mouth-piece, by which the diver draws in the air.

A great improvement in the diving-bell was made by the late Mr. Spalding, of Edinburgh. This construction seems designed to remedy some inconveniences of Dr. Halley's, which are very evident, and of a very dangerous tendency. These are, 1. By Dr. Halley's construction the sinking or raising of the bell depends entirely on the people who are at the surface of the water; and as the bell even when in the water has a very considerable weight, the raising it not only requires a great deal of labour, but there is a possibility of the rope breaking by which it is raised, and thus every person in the bell would inevitably perish. 2. As there are, in many parts of the sea, rocks which lie at considerable depth, the figure of which cannot possibly be perceived from above, there is danger that some of their ragged prominences may catch hold of one of the edges of the bell in its decent, and thus overset it before any signal can be given to those above, which would infallibly be attended with the destruction of the people in the bell; and as it must always be unknown, before trial, what kind of a bottom the sea has in any place, it is plain, that without some contrivance to obviate this last danger, the descent in Dr. Halley's diving-bell is not at all eligible.

How these inconveniences are remedied by Mr. Spalding's new contrivance, will be easily understood from the following description. A B C D, fig. 52, represents a section of the bell, which is made of wood; *e*, *e*, are iron hooks, by means of which it is suspended by ropes Q B F *e*, and Q A E *e*, and Q S, as expressed in the figure: *c*, *c*, are iron hooks, to which are appended leaden weights, that keep the mouth of the bell always parallel to the surface of the water, whether the machine taken altogether is lighter or heavier than an equal bulk of water. By these weights alone, however, the bell would not sink: another is therefore added, represented at L, and which can be raised or lowered at pleasure, by means of a rope passing over the pulley *a*, and fastened to one of the sides of the bell at M. As the bell descends, this weight, called by Mr. Spalding the balance-weight, hangs down a considerable way below the mouth of the bell. In case the edge of the bell is caught by any obstacle, the balance-weight is immediately lowered down so that it may rest upon the bottom. By this means the bell is lightened, so that all danger of oversetting is removed; for being lighter, without the balance-weight, than an equal bulk of water, it is evident that the bell will rise, as far as the length of the rope affixed to the balance-weight will allow it. This weight, therefore, will serve as a kind of anchor to keep the bell at any particular depth which the divers may think necessary; or by pulling it quite up the descent may be continued to the very bottom.

By another very ingenious contrivance Mr. Spalding rendered it possible for the divers to raise the bell, with all the weights appended to it, even to the surface, or to stop at any particular depth, as they think proper; and thus they could still be safe, even though the rope designed for pulling up the bell was broken. For this purpose the bell is divided into two cavities, both of which are made as tight as possible. Just above the second bottom E F, are small slits in the sides of the bell, through which the water, entering as the bell descends, displaces the air originally contained in its cavity, which flies out at the upper orifice of the cock G H. When this is done, the divers turn the handle G, which stops the cock; so that if any more air was to get into the cavity A E F B, it could no longer be discharged through the orifice H as before. When this cavity is full of water the bell sinks; but when a considerable quantity of air is admitted it rises. If therefore the divers have a mind to raise themselves, they turn the small cock G, by which a communication is made between the upper and under cavities of the bell. The consequence of this is, that a quantity of air immediately enters the upper cavity, forces out a quantity of the water contained in it, and thus renders the bell lighter by the whole weight of the water which is displaced. Thus if a certain quantity of air is admitted into the upper cavity the bell will descend very slowly; if a greater quantity, it will neither ascend nor descend, but remain stationary; and if a larger quantity of air be still admitted it will rise to the top. It is to be observed, however, that the air which is thus let out into the upper cavity must be immediately replaced from the air-barrel; and the air is to be let out very slowly, or the bell will rise to the top with so great velocity that the divers will be in danger of being shaken out of their seats. But by following these directions every possible accident may be prevented, and people may descend to very great depths without the least appehension of danger. The bell also becomes so easily manageable in the water, that it may be conducted from one place to another by a small boat with the greatest ease, and with perfect safety to those who are in it.

Instead of wooden seats used by Dr. Halley, Mr. Spalding made use of ropes suspended by hooks *bbb*; and on these ropes the divers may sit without any inconvenience. There are two windows made of thick strong glass, for admitting light to the divers. N represents an air-cask with its tackle, and O C P the flexible pipe through which the air is admitted to the bell. In the ascent and descent of this cask the pipe is kept down by a small appended weight, as in Dr. Halley's machine. R is a small cock by which the hot air is discharged as often as it becomes troublesome. Annexed is a representation of the whole diving apparatus, which, no doubt, will be readily understood without any further explanation. Two air-barrels are represented in this figure; but Mr. Spalding was of opinion that one, capable of containing thirty gallons, is sufficient for an ordinary machine. See fig. 53.

Mr. Adam Walker recommends, for the purpose of diving, a conical tub of wood three feet diameter at the bottom, two and a half feet at the top, and three feet high, so loaded with lead at the bottom as just to sink itself, with a small seat for the diver. See Plate, fig. 54. A bent metal tube is attached to the outside of the bell, as *abc*, with a stop-cock *a*, and a flexible leathern tube to the other end at *c*; this tube terminates in a forcing air-pump fastened to the side of a ship; *d* is a solid piston acted upon by a lever *e*; upon the piston being drawn up the air rushes in at the valve *g*, and fills the space *n*; in its descent the valve *g* shuts, and the coni-

cal valve o opens, and thus the air is forced down the hose into the bell. The pump is kept working, while the diver, by opening and shutting the stop-cock, is abundantly supplied with fresh air, and that which is vitiated is forced out at the bottom of the bell. By a machine of this kind the greatest part of the wreck was saved from the rich ship Belgiosa.

Mr. Smeaton's diving-bell was a square chest of cast-iron, four and a half feet in height, four and a half feet in length, and three feet wide, and afforded room for two men to work in it. It was supplied with fresh air by a forcing-pump. This was used with great success at Ramsgate. Other contrivances as intimated before have been used for diving to small depths; such as strong cases for the body, to keep off the pressure of the water, which were supplied with fresh air by pipes from the surface.

The most effectual of this kind is a method put in practice by a gentleman of Devonshire. He has contrived a large case of strong leather, perfectly water-proof, which may hold about half a hogshead of air. This is so adapted, that, when he shuts himself up in this case, he may walk at the bottom of the sea, and go into any part of a wrecked vessel, and deliver out the goods. This method, we are told, he has practised for many years, and has thus acquired a large fortune. It would be a considerable improvement of this machine to condense the air in it as much as possible before the diver descended, as he would thus be furnished with an atmosphere endued with an elasticity sufficient to resist the weight of water, which otherwise would squeeze his case into much less room than it originally took up. The condensed air would serve for respiration a much longer time than that which is in its ordinary state.

Diving-bladder, a machine invented by Borelli, and by him preferred, though without any good reason, to the diving-bell. It is a globular vessel of brass or copper about two feet in diameter, formed to contain the diver's head. It is fixed to a goats'-skin habit, exactly fitted to his person. Within the vessel are pipes, by means of which a circulation of air is contrived; and the person carries an air-pump by his side, by which he can make himself heavier or lighter, as fishes do by contracting or dilating their air-bladders. By this means he thought all the objections to which other diving-machines are liable were entirely obviated, and particularly that of want of air; the air which had been breathed being, as he imagined, deprived of its noxious qualities by circulating through the pipes. These advantages, however, it is evident, are only imaginary. The diver's limbs being defended from the pressure of the water only by a goat's skin, would infallibly be crushed if he descended to any considerable depth; and from the discoveries made by Dr. Priestly and others, it is abundantly evident that air which is once rendered foul by breathing, cannot in any degree be restored by circulation through pipes. Concerning the use of copper machines in general Mr. Spalding has remarked, that when a person has breathed in them a few minutes, he feels in his mouth a very disagreeable brassy taste, which continues all the time he remains in the vessel; so that, on this account, copper seems by no means an eligible material.

Diving, submarine vessel for. The following description of a diving-machine, invented by Mr. Bushnell, of Connecticut, is given in the Transactions of the American Philosophical Society.

The external shape of the submarine vessel bore some resemblance to two upper tortoise-shells of equal size, joined together; the place of entrance into the vessel being represented by the opening made by the swell of the shells, at the head of the animal. The inside was capable of containing the operator, and air sufficient to support him thirty minutes without receiving fresh air. At the bottom, opposite to the entrance, was fixed a quantity of lead for ballast. At one edge, which was directly before the operator, who sat upright, was an oar for rowing forward or backward. At the other edge was a rudder for steering. An aperture, at the bottom, with its valve, was designed to admit water, for the purpose of descending; and two brass forcing-pumps served to eject the water within, when necessary for ascending. At the top there was likewise an oar for ascending or descending, or continuing at any particular depth. A water-gauge, or barometer, determined the depth of descent, a compass directed the course, and a ventilator within supplied the vessel with fresh air, when on the surface.

The entrance into the vessel was elliptical, and so small as barely to admit a person. This entrance was surrounded with a broad elliptical iron band, the lower edge of which was let into the wood of which the body of the vessel was made, in such a manner as to give its utmost support to the body of the vessel against the pressure of the water. Above the upper edge of this iron band there was a brass crown, or cover, resembling a hat with its crown and brim, which shut water-tight upon the iron band: the crown was hung to the iron band with hinges, so as to turn over sideways when opened. To make it perfectly secure when shut, it might be screwed down upon the band by the operator, or by a person without.

There were in the brass crown three round doors, one directly in front, and one on each side, large enough to put the hand through. When open they admitted fresh air; their shutters were ground perfectly tight into their places with emery, hung with hinges, and secured in their places when shut. There were likewise several small glass windows in the crown for looking through, and for admitting light in the day-time, with covers to secure them. There were two air-pipes in the crown. A ventilator within drew fresh air through one of the air-pipes, and discharged it into the lower part of the vessel; the fresh air introduced by the ventilator expelled the impure light air through the other air-pipe. Both air-pipes were so constructed, that they shut themselves whenever the water rose near their tops, so that no water could enter through them, and opened themselves immediately after they rose above the water.

The vessel was chiefly filled with lead fixed to its bottom; when this was sufficient, a quantity was placed within, more or less, according to the weight of the operator; its ballast made it so stiff, that there was no danger of oversetting. The vessel with all its appendages,

and the operator, was sufficient to settle it very low in the water. About two hundred pounds of the lead, at the bottom for ballast, would be let down forty or fifty feet below the vessel; this enabled the operator to rise instantly to the surface of the water, in case of accident.

When the operator would descend, he placed his foot on the top of a brass valve, depressing it, by which he opened a large aperture in the bottom of the vessel, through which the water entered at his pleasure; when he had admitted a sufficient quantity, he decended very gradually; if he admitted too much, he ejected as much as was necessary to obtain an equilibrium by the two brass forcing-pumps placed at each hand. Whenever the vessel leaked, or he would ascend to the surface, he also made use of these forcing-pumps. When the skilful operator had obtained an equilibrium, he could row upward or downward, or continue at any particular depth, with an oar placed near the top of the vessel, formed upon the principle of the screw, the axis of the oar entering the vessel; by turning the oar one way he raised the vessel, by turning it the other way he depressed it.

A glass tube eighteen inches long, and one inch in diameter, standing upright, its upper end closed, and its lower end which was open, screwed into a brass pipe, through which the external water had a passage into the glass tube, served as a water-gauge or barometer. There was a piece of cork, with phosphorus on it, put into the water-gauge. When the vessel descended the water rose in the water-gauge, condensing the air within, and bearing the cork, with its phosphorus, on its surface. By the light of the phosphorus the ascent of the water in the gauge was rendered visible, and the depth of the vessel under water ascertained by a graduated line.

An oar, formed upon the principle of the screw, was fixed in the fore part of the vessel; its axis entered the vessel, and being turned one way, rowed the vessel forward, but being turned the other way rowed it backward; it was made to be turned by the hand or foot.

A rudder, hung to the hinder part of the vessel, commanded it with the greatest ease. The rudder was made very elastic, and might be used for rowing forward. Its tiller was within the vessel, at the operator's right-hand, fixed at a right-angle, on an iron rod which passed through the side of the vessel; the rod had a crank on its outside end, which commanded the rudder, by means of a rod extending from the end of the crank to a kind of tiller, fixed upon the left-hand of the rudder. Raising and depressing the first-mentioned tiller, turned the rudder as the case required.

A compass marked with phosphorus directed the course, above and under the water; and a line and lead sounded the depth when necessary.

The internal shape of the vessel, in every possible section of it, verged towards an ellipsis, as near as the design would allow; but every horizontal section, although elliptical, yet was as near to a circle as could be admitted. The body of the vessel was made exceedingly strong; and to strengthen it as much as possible a firm piece of wood was framed, parallel to the conjugate diameter, to prevent the sides from yielding to the great pressure of the incumbent water in a deep immersion. This piece of wood was also a seat for the operator.

Every opening was well secured. The pumps had two sets of valves. The aperture at the bottom, for admitting water, was covered with a plate, perforated full of holes to receive the water, and prevent any thing from choking the passage, or stopping the valve from shutting. The brass valve might likewise be forced into its place with a screw, if necessary. The air-pipes had a kind of hollow sphere, fixed round the top of each, to secure the air-pipe valves from injury: these hollow spheres were perforated full of holes, for the passage of the air through the pipes: within the air-pipes were shutters to secure them, should any accident happen to the pipes or the valves on their tops.

Wherever the external apparatus passed through the body of the vessel, the joints were round, and formed by brass pipes, which were driven into the wood of the vessel; the holes through the pipes were exactly made, and the iron rods, which passed through them, were turned in a lathe to fit them; the joints were also kept full of oil, to prevent rust and leaking. Particular attention was given to bring every part, necessary for performing the operations, both within and without the vessel, before the operator, and as conveniently as could be devised; so that every thing might be found in the dark, except the water-gauge and the compass, which were visible by the light of the phosphorus; and nothing required the operator to turn to the right hand, or to the left, to perform any thing necessary.

The inventor next pursues the subject under the following heads:

1. Description of a magazine, and its appendages, designed to be conveyed by the submarine vessel to the bottom of a ship. In the fore part of the brim of the crown of the submarine vessel were a socket, and an iron tube passing through the socket: the iron tube stood upright, and could slide up and down in the socket six inches: at the top of the tube was a wood screw, fixed by means of a rod, which passed through the tube, and screwed the wood screw fast upon the top of the tube: by pushing the wood screw up against the bottom of a ship, and turning it at the same time, it would enter the planks; driving would also answer the same purpose: when the wood screw was firmly fixed it could be cast off by unscrewing the rod, which fastened it upon the top of the tube.

Behind the submarine vessel was a place, above the rudder, for carrying a large powder-magazine; this was made of two pieces of oak timber, large enough, when hollowed out, to contain 150 pounds of powder, with the apparatus used in firing it, and was secured in its place by a screw, turned by the operator. A strong piece of rope extended from the magazine to the wood screw above-mentioned, and was fastened to both. When the wood screw was fixed, and to be cast off from its tube, the magazine was to be cast off likewise by unscrewing it, leaving it hanging to the wood screw; it was lighter than the water, that it might rise up against the object to which the wood screw and itself were fastened.

Within the magazine was an apparatus, constructed to run any proposed length of time: it unpinioned a strong lock resembling a gun-lock, which gave fire to the powder. This apparatus was so pinioned that it could not possibly move till, by casting off the magazine from the vessel, it was set in motion.

The skilful operator could swim so low on the surface of the water as to approach very near a ship in the night, without fear of being discovered; and might, if he chose, approach the stem or stern above water with very little danger. He could sink very quickly, and keep at any depth he pleased, and row a great distance in any direction he desired, without coming to the surface; and when he rose to the surface, he could soon obtain a fresh supply of air, when, if necessary, he might descend again, and pursue his course.

2. Experiments made to prove the nature and use of a submarine vessel. The first experiment made was with about two ounces of gunpowder, which were exploded four feet under water, to prove to some of the first personages in Connecticut, that powder would take fire under water.

The second experiment was made with two pounds of powder, inclosed in a wooden bottle, and fixed under a hogshead, with a two-inch oak plank between the hogshead and the powder; the hogshead was loaded with stones as deep as it could swim; a wooden pipe descending through the lower head of the hogshead, and through the plank, into the powder contained in the bottle, was primed with powder. A match put to the priming, exploded the powder; which produced a very great effect, rending the plank into pieces, demolishing the hogshead, and casting the stones and the ruins of the hogshead, with a body of water, many feet into the air, to the astonishment of the spectators. This experiment was likewise made for the satisfaction of the gentlemen abovementioned.

There were afterwards made many experiments of a similar nature, some of them with large quantities of powder; they all produced very violent explosions, much more than sufficient for any purpose had in view.

In the first essays with the submarine vessel, the inventor took care to prove its strength to sustain the great pressure of the incumbent water, when sunk deep, before he trusted any person to descend below the surface: and he never suffered any person to go under water without a strong piece of rigging made fast to it, until he found him well acquainted with the operations necessary for his safety. After this he made him descend, and continue at particular depths without rising or sinking, row by the compass, approach a vessel, go under her, and fix the wood screw into her bottom, &c. until he thought him sufficiently expert to put any design into execution.

It required many trials to make a person of common ingenuity a skilful operator: the first employed was very ingenious, and made himself master of the business, but was taken sick in the campaign of 1776, at New-York, before he had an opportunity to make use of his skill, and never recovered his health sufficiently afterwards.

3. Experiments made with a submarine vessel. After various attempts to find an operator to his wish, Mr. Bushnell sent one, who appeared more expert than the rest, from New York to a fifty-gun ship, lying not far from Governor's-island. He went under the ship, and attempted to fix the wood screw into her bottom; but struck, as he supposes, a bar of iron, which passes from the rudderhinge, and is spiked under the ship's quarter. Had he moved a few inches, which he might have done without rowing, he would probably have found wood where he might have fixed the screw; or, if the ship were sheathed with copper, he might easily have pierced it: but not being well skilled in the management of the vessel, in attempting to move to another place, he lost the ship; after seeking her in vain, for some time, he rowed some distance, and rose to the surface of the water, but found day-light had advanced so far, that he durst not renew the attempt. The adventurer said that he could easily have fastened the magazine under the stem of the ship, above water, as he rowed up to the stern, and touched it before he descended. Had he fastened it there, the explosion of 150 pounds of powder (the quantity contained in the magazine), must have been fatal to the ship. In his return from the ship to New York he passed near Governor's-island, and thought he was discovered by the enemy on the island; being in haste to avoid the danger he feared, he cast off the magazine, as he imagined it retarded him in the swell, which was very considerable. After the magazine had been cast off one hour, the time the internal apparatus was set to run, it blew up with great violence.

Afterwards there were two attempts made in Hudson's river, above the city, but they effected nothing. One of them was by the afore-mentioned person. In going towards the ship, he lost sight of her, and went a great distance beyond her: when he at length found her, the tide ran so strong, that as he descended under water for the ship's bottom, it swept him away. Soon after this the enemy went up the river, and pursued the boat which had the submarine vessel on board, and sunk it with their shot. "Though," says Mr. Bushnell, "I afterwards recovered the vessel, I found it impossible, at that time, to prosecute the design any further. I had been in a bad state of health from the beginning of my undertaking, and was now very unwell; the situation of public affairs was such that I despaired of obtaining the public attention, and the assistance necessary. I was unable to support myself, and the persons I must have employed, had I proceeded. Besides, I found it absolutely necessary that the operators should acquire more skill in the management of the vessel before I could expect success, which would have taken up some time, and made no small additional expense. I therefore gave over the pursuit for that time, and waited for a more favourable opportunity, which never arrived."

4. Other experiments made with a design to fire shipping. In the year 1777 Mr. Bushnell made an attempt from a whale-boat against the Cerberus frigate, then lying at anchor between Connecticut river and New London, by drawing a machine against her side, by means of a line. The machine was loaded with powder, to be exploded by a gun-lock, which was to be unpinioned by an apparatus, to be turned by being brought alongside of the frigate. This machine fell in with a schooner at anchor, astern of the frigate, and concealed from his sight. By some means or other it was fired, and demolished the schooner and three men; and blew the only one left alive overboard, who was taken up very much hurt.

After this he fixed several kegs under water, charged with powder, to explode, upon touching any thing, as

they floated along with the tide; he set them afloat in the Delaware, above the English shipping at Philadelphia, in December 1777. "I was unacquainted," says he, "with the river, and obliged to depend upon a gentleman very imperfectly acquainted with that part of it, as I afterwards found. We went as near the shipping as we durst venture; I believe the darkness of the night deceived him, as it did me. We set them adrift to fall with the ebb upon the shipping. Had we been within 60 rods, I believe they must have fallen in with them immediately as I designed; but as I afterwards found, they were set adrift much too far distant, and did not arrive until after being detained some time by frost: they advanced in the day-time in a dispersed situation, and under great disadvantages. One of them blew up a boat with several persons in it, who imprudently handled it too freely, and thus gave the British that alarm which brought on the battle of the Kegs.

DIVISIBILITY, that property by which the particles of matter in all bodies are capable of a separation, or disunion from each other.

Some philosophical writers have considered this as a distinct property of matter itself, but it may with more propriety be considered as a property of extension; for we can easily conceive that a given extension may be divided into any number of parts, let it be ever so great; but it is by no means known whether matter is or is not capable of being divided ad infinitum, that is, without any limit.

That a certain extension, as an inch, or any other length, be it ever so small, is capable of infinite division, may be rendered evident by means of arithmetic or of geometry. We may take, for instance, the halves of the proposed extension, then the halves of those parts, and so on without end; for if you proceed in this manner ever so far, there will after all still remain the halves of the last parts, which may be also divided into other halves, &c. Again, suppose the line A B, Plate XLIV. Miscel. fig. 55, to be the proposed extension. Through the extreme points of this line draw two indefinite lines EF and CD, parallel to each other. In one of those lines, as EF, take a point L, and from this point draw straight lines to any parts of the line DC, every one of which lines will evidently cut the proposed extension AB in a different point. Now as the line BD may be produced towards D without limitation, and straight lines may be drawn from L to an infinite number of points in the extended line BD; therefore the extension AB may be divided without end, or beyond any assignable number of parts.

Or thus: suppose a line A D, Plate XLIV. Miscel. fig. 56, perpendicular to BF; with the centres C, C, C, &c. and distances CA, CA, &c. describe circles cutting the line GH in the points *e*, *e*, &c. Now the greater the radius AC is, the less is the part *e* G; but the radius may be augmented in infinitum, and therefore the part *e* G may be diminished in the same manner; and yet it can never be reduced to nothing, because the circles can never coincide with the right line B F. Consequently, the parts of any magnitude may be diminished in infinitum.

Thus far we have shown that extension may be divided into an unlimitted number of parts; but with respect to the limits of the divisibility of matter itself we are perfectly in the dark. We can indeed divide certain bodies into surprisingly fine and numerous particles, and the works of nature offer many fluids and solids of wonderful tenuity; but both our efforts, and those naturally small objects, advance a very short way towards infinity. Ignorant of the intimate nature of matter, we cannot assert whether it may be capable of infinite division, or whether it ultimately consists of particles of a certain size, and of perfect hardness. We shall now add some instances of the wonderful tenuity of certain bodies, which have been produced either by art, or discovered by means of microscopical observations amongst the stupendous works of nature.

The spinning of wool, silk, cotton, and such-like substances, affords no bad specimens of this sort; since the thread which has been produced by this means has often been so very fine as almost to exceed the bounds of credibility, had it not been sufficiently well authenticated. Mr. Boyle mentions that two grains and a half of silk was spun into a thread 300 yards long. A few years ago a lady of Lincolnshire spun a single pound of woollen yarn into a thread of 168,000 yards long, which is equal to 95 English miles. Also a single pound-weight of fine cotton-yarn was lately spun, in the neighbourhood of Lancaster, into a thread 134,400 yards long.

The ductility of gold likewise furnishes a striking example of the great tenuity of matter amongst the productions of human ingenuity. A single grain-weight of gold has been often extended into a surface equal to 50 square inches. If every square inch of it is divided into square particles of the hundredth part of an inch, which will be plainly visible to the naked eye, the number of those particles in one inch square will be 10,000; and multiplying this number by the 50 inches, the product is 500,000; that is, the grain of gold may be actually divided into at least half a million of particles, each of which is perfectly apparent to the naked eye. Yet if those particles are viewed in a good microscope, they will appear like a large surface, the ten-thousandth part of which might by this means be easily discerned.

An ingenious artist in London has been able to draw parallel lines upon a glass plate, as also upon silver, so near one another, that 10,000 of them occupy the space of one inch. Those lines can be seen only by the assistance of a very good microscope. Another workman has drawn a silver wire, the diameter of which does not exceed the 750th part of an inch. But those prodigies of human ingennity will appear extremely gross and rude, if they are compared with the immense subtility of matter which may every where be observed amongst the works of nature. The animal, the vegetable, and even the mineral kingdom, furnish numerous examples of this sort.

What must be the tenuity of the odoriferous parts of musk, when we find that a piece of it will scent a whole room in a short time, and yet it will hardly lose any sensible part of its weight! But supposing it to have lost one-hundredth part of a grain weight, when this small quantity is divided and dispersed through the whole room, it must so expand itself as not to leave an inch square of space where the sense of smell may not be af-

fected by some of its particles. How small must then be the weight and size of one of those particles!

The human eye, unassisted by glasses, can frequently perceive insects so small as to be barely discernible. The least reflection must show that the limbs, the vessels, and other parts of such animals, must infinitely exceed in fineness every endeavour of human art. But the microscope has discovered wonders that are vastly superior, and such indeed as were utterly unknown to our forefathers, before the invention of that noble instrument.

Insects have been discovered so small as not to exceed the 10,000th part of an inch: so that 1,000,000,000,000 of them might be contained within the space of one cubic inch; yet each animalcule must consist of parts connected with each other; with vessels, with fluids, and with organs necessary for its motions, for its increase, for its propagation, &c. How inconceivably small must those organs be! and yet they are unquestionably composed of other parts still smaller, and still farther removed from the perception of our senses.

Several writers, when treating of the divisibility of matter, have mentioned two curious theorems, which are established on the supposition that matter is divisible without end.

Theorem I. A quantity of matter, however small, and any finite space, however large, being given, it is possible that matter may be diffused through all that space, and so fill it, as not to leave in it a pore, whose diameter will exceed a given right line.

Let the given space be a cube, whose side is A B, so that the cube be equal to $\overline{A B}.^3$ and let the quantity of matter be represented by b^3; also let a line D be the limit of the diameter of the pores.

The side A B being a finite quantity, may be conceived to be divisible into parts equal to the line D. Let the number of those parts be represented by n, so that n D = A B, and n^3 $D^3 = \overline{A B}.^3$. Conceive the given space to be divided into cubes, each of whose sides be equal to the right line D, and the number of those cubes will be n^3, which cubes may be represented by E, F, G, H. Again, let the particle b^3 be supppsed to be divided into parts whose number is n^3; and in each cubic space let there be placed one of those particles, by which means the matter b^3 will be diffused through all the given space. Besides, each particle being placed in its cell, may be formed into a concave sphere, whose diameter may be equal to the given line D; whence it will follow, that each sphere will touch that which is next to it; and thus the quantity of matter b^3, be it ever so small, will fill the given finite space, however large, in such a manner as not to leave in it a pore larger in diameter than the given line D.

Corollary. There may be a given body, whose matter if it be reduced into a space absolutely full, that space may be any given part of the former magnitude.

Theorem II. There may be two bodies equal in bulk, whose quantities of matter may be very unequal, and though they have any given ratio to each other, yet the sums of the pores or empty spaces in those bodies may almost approach the ratio of equality.

The demonstration of this theorem is easily derived from the foregoing: for since the matter of a body may be conceived to be condensable into any part of the original bulk; therefore supposing two bodies, A and B, of equal bulk, to be such that the matter of A be 100 times the matter of B; the matter of B may be conceived to be condensed into 1,000,000th part of its original bulk, and of course the matter of A will be condensed into one hundred 1,000,000th parts of the same bulk; in which case the spaces left in the original bulk of B will be to the spaces left in the original bulk of A, as 999,999 to 999,900, which numbers are nearly equal to each other.

Instead of the above-mentioned numbers, the proportions of the quantities of matter may be increased at pleasure, and so may the proportion of the original bulks of the bodies to the spaces into which they may be conceived to be condensable.

DIVISION, in arithmetic, one of the four fundamental rules, by which we find how often a less number, called the divisor, is contained in a greater, called the dividend; the number of times which the divisor is contained in the dividend being termed the quotient. See ARITHMETIC, and ALGEBRA.

DIVISION, in natural philosophy, is the taking a thing to pieces, in order to have a more complete conception of the whole: this is frequently necessary in examining very complex beings, the several parts of which cannot be surveyed at one view. Thus to learn the nature of a watch the workman takes it to pieces, and shows us the spring, wheels, axles, pinions, balances, dial-plate, pointer, case, &c. and after describing the uses and figures of each of them apart, explains how they contribute to form the whole machine. See CLOCKWORK.

DIVISION, in music. This word bears two constructions. With theoretical musicians it implies the division of the intervals of the octave; but taken in a practical sense signifies a long series of notes so running into each other as to form one connected chain of sounds; and which, in vocal music, is always applied to a single syllable. The singing or playing a passage of this kind is called running a division.

DIVISION, in the sea language, the third part of a fleet of men of war, and sometimes the ninth part; which last happens when the fleet is divided into three squadrons: for then each squadron is distributed into three divisions.

DIVORCE, a separation of two de facto married together, of which there are two kinds; one a vinculo matrimonii, from the very bond of marriage; the other a mensa et thora, from bed and board.

Causes for separation a vinculo are consanguinity or affinity within the degrees prohibited, also impuberty or frigidity; where the marriage was actually void ab initio, and the sentence of divorce only declaratory of its being so. This divorce enables the parties to marry again; but in the other case a power for so doing must be obtained by act of parliament. The woman divorced a vinculo matrimonii receives all again she brought with her.

Divorce a mensa et thora is where the use of matrimony, as the use of cohabitation of the married persons, or their mutual conversation, is prohibited for a time, or without limitation of time. And this is in cases of adultery, cruelty, or the like; in which case the marriage having been originally good is not dissolved or af-

fected as to the vinculum or bond. The woman under separation by this divorce may sue by her next friend; and she may sue her husband in her own name for alimony. Wood's Inst. 62. But the children which she has after her divorce shall be deemed bastards; for a due obedience to the sentences will be intended, unless the contrary be shown. Walk. 123.

DIURETICS, in pharmacy, such medicines as increase the discharge of urine; or which are supposed to have a power of removing obstructions in the urinary passages. See MATERIA MEDICA.

DIURNAL, in astronomy, something relating to the day, in opposition to nocturnal, which regards the night.

DIURNAL ARCH, the arch or number of degrees that the sun, moon, or stars, describe between their rising and setting.

DIURNAL *motion of a planet*, is so many degrees and minutes as any planet moves in 24 hours. Hence the motion of the earth about its axis is called its diurnal motion. See ASTRONOMY.

DIURNARY, *diurnarius*, an officer in the Greek empire, who wrote down in a book, kept for that purpose, whatever the prince did, or ordered, &c. every day.

DIVOTO, in music, a term signifying that the piece before which it is written is to be performed in a grave, solemn style, proper to inspire devotion.

DIVUS and DIVA, in antiquity, appellations given to men and women as had been deified. We find this title on medals struck for the consecration of an emperor or empress: thus, DIVVS IVLIVS, DIVA FAVSTINA AVG. &c.

DO, in music, a monosyllable long since substituted by the Italians for that of *ut*, which Guido applied to the first note of the natural major, diatonic scale. Guido's monosyllable was rejected as too hard and rough.

DOCIMASIA, in Greek antiquity, a probation of the magistrates and persons employd in public business at Athens. It was performed publicly in the forum, where they were obliged to give account of themselves and their past life before certain judges. Among several questions proposed to them we find the following: Whether they had been dutiful to their parents; had served in the wars, and had a competent estate.

DOCIMASTIC ART, a name given to the art of assaying by operations on a small scale, the nature and quantity of metallic or other matters which are obtained from minerals, &c.

DOCK, or DOCKING, in law, an expedient for cutting off an estate-tail in lands or tenements, that the owner may be enabled to sell, give, or bequeath the same.

DOCK, in maritime affairs, is an artificial bason, by the side of an harbour, made convenient either for the building or repairing of ships. It is of two sorts, 1. Dry-dock, where the water is kept out by great floodgates, till the ship is built or repaired, when the gates are opened, and the water let in to float and launch her. 2. Wet-dock, a place where the ship may be hauled into, out of the tide's way, and so dock herself, or sink herself a place to lie in.

The West-India docks, in the isle of Dogs. These immense works are intended to receive the whole of the ships in the West India trade; and may be accounted among the prominent curiosities of British commerce. They were undertaken according to an act of parliament, passed in 1799, entitled "the West India Dock Act." The entrances into them are at Blackwall and Limehouse-hole; their site is wholly on the isle of Dogs; and upon the wharfs and quays adjoining them, all West India ships are to unload and load their cargoes.

The northern dock for unloading inwards covers a space of thirty acres, and is capable of containing from two to three hundred sail of ships. The smaller dock, situated to the south of the other, covers an area of 24 acres, and is devoted solely to the business of loading outwards. Both docks are surrounded by a series of immense warehouses.

The proprietors of this capital improvement are styled "the West India Dock company:" they commenced their undertaking with a subscription of 500,000*l.* and are empowered to increase it to 600,000*l.* if needful. They are reimbursed by a tonnage of 6*s.* upon the burthen of every ship which enters the docks; for wharfage, landing, housing, weighing, cooperage, and warehouse-room, they are entitled to certain rates upon all goods that are discharged, such as 8*d* per cwt. upon sugar; 1*d* per gallon upon rum; 1*s.* 6*d.* per cwt. upon coffee; 2*s.* 6*d.* per cwt. upon cotton-wool, &c. &c.

Notwithstanding these docks occasion a very important trade to be removed to a considerable and even inconvenient distance from the metropolis, yet the advantages to the port of London will, upon the whole, be considerable. The West India trade generally arrives in fleets, and occasions so much crowding, confusion, and damage, in the river, that the ships being disposed of in these docks, the overgrown trade of the port may be carried on with pleasure and convenience.

Canal at the isle of Dogs. To enable shipping in their passages up and down the Thames to avoid the circuitous and inconvenient course round the isle of Dogs, a canal is now cut across this peninsula, through which, upon paying certain moderate rates, all ships, vessels, and craft, will be permitted to pass in their passage up and down the Thames. For three years after its completion ships above two hundred tons will be required to pay 1*d.* per ton; from two hundred to one hundred tons 1½*d.* per ton; from one hundred to 50 tons 10*s.* per vessel; from fifty to twenty tons 5*s.* per vessel; and for boats and craft 1*s.* each.

The docks at Wapping. This important improvement is made in the angle formed by the Thames, between Hermitage dock and Shadwell dock. One immense dock, called St. George's dock, covers the space extending from Virginia-street, almost to Old Gravel-lane, in one direction, and in the other from Artichoke-lane to the south side of Pennington-street. This dock alone is capable of holding two hundred ships, with room for shifting. Another dock, called Shadwell dock, adjoining to the other, will hold about fifty ships. The entrance to the docks is from the Thames by three basons, capable of containing an immense quantity of small craft; and the inlets from the Thames into the basons are at the Old Hermitage dock, at Old Wapping dock, and Old Shadwell dock.

The capital of the company is 1,200,000*l.* The shares bear a premium. The ultimate profits upon the scheme

are limited to 10 per cent.; an interest which it is sure to realize.

On the 26th of June, 1802, the foundation of the entrance bason was laid by the then chancellor of the exchequer, the right honourable Henry Addington; and the first stone of a tobacco warehouse, which is the largest in the world, the roof of which covered six acres of ground; and also the first stone of a range of warehouses for general merchandise, were laid at the same time.

The warehouses for the reception of tobacco are situated at the eastern extremity; they are two in number. The largest is 762 feet long, and 160 feet wide, equally divided by a strong partition-wall, with double iron doors; the smallest is 250 feet by 200. Both of them consist of a ground-floor and vaults; the first is to be wholly applied to the reception of tobacco; the cellars in the smaller warehouses are appropriated to the housing of wine. They are solely under the care and controul of the officers of the customs: the proprietors of the docks having nothing more to do with them than to receive the rent.

Dock-yrads, in ship-building, are magazines of all sorts of naval stores. The principal in England are those of Chatham, Portsmouth, Plymouth, Woolwich, Deptford, and Shreeness. In time of peace ships of war are laid up in these docks; those of the first rate mostly at Chatham, where, and at other yards, they receive from time to time such repairs as are necessary. These yards are generally supplied from the northern powers with hemp, pitch, tar, rosin, &c. but as for masts, particularly those of the larger size, they are brought from America.

DOCKET, or Dogget, a brief in writing, on a small piece of paper or parchment, containing the effect of a larger writing, and annexed to other papers for particular purposes. In law a docket is necessary in all judgments; and no debts will be entitled to a preference, in debts due from a party deceased, as judgment debts, unless such judgments be regularly docketed.

DOCTOR, a teacher, or person who has passed all the degrees of a faculty, and is impowered to teach or practise the same: thus we say, doctor in divinity, doctor in physic, doctor of laws.

The title of doctor seems to have been created in the twelfth century, instead of master, and established with the other scholastic degrees of bachelors and licentiates, by Peter Lombard and Gilbert Porreus, then the chief divines of the university of Paris. Gratian did the same thing, at the same time, in the university of Bologna. Though the two names of doctor and master were used a long time together, yet many think that their functions were different, the masters teaching the human sciences, and the doctors those sciences depending on revelation and faith. Spelman takes the title of doctor not to have commenced till after the publication of Lombard's Sentences, about the year 1140, and affirms that such as explained that work to their scholars were the first that had the appellation of doctors.

To pass doctor in divinity at Oxford, it is necessary that the candidate have been four years bachelor of divinity. For doctor of laws he must have been seven years in the university to commence bachelor of law, five years after which he may be admitted doctor of laws. Otherwise, in three years after taking the degree of master of arts, he may take the degree of bachelor in laws, and in four years more that of doctor: which same method and time are likewise required to pass the degree of doctor in physic. At Cambridge, to take the degree of doctor in divinity, it is required the candidate have been seven years bachelor of divinity: though in several colleges the bachelor's degree in dispensed with, and they may go out per saltum. To commence doctor in laws, the candidate must have been five years bachelor of laws, or seven years master of arts. To pas doctor in physic, he must have been bachelor in physic five years, or seven years master of arts.

Doctors, and bachelors of divinity and law, may have a dispensation for nonresidence. 21 Hen. VIII. cap. 13. Doctors of civil law may exercise ecclesiastical jurisdiction, although laymen. 37 H. VIII. c. 17.

Doctor is also an appellation adjoined to several specific epithets, expressing the merit of some of the schoolmen: thus Alexander Hales is called the irrefragable doctor; Thomas Aquinas the angelic doctor; St. Bonaventure the seraphic doctor; John Duns Scotus the subtile doctor; Raimond Lully the illuminated doctor; Roger Bacon the admirable doctor, &c.

Doctors'-commons. See College of Civilians.

DODARTIA, a genus of the didynamia angiospermia class and order of plants, the flower of which consists of one ringent petal, with the upper lip erect and semibifid; and the lower lip patent, twice broader than long, and trifid; the fruit is a globose bilocular capsule, containing a great number of very small seeds. There are two species, herbaceous plants of the East.

DODECAGON, in geometry, a regular polygon, consisting of twelve equal sides and angles.

DODECAHEDRON, in geometry, one of Platonic bodies, or regular solids, contained under twelve equal and regular pentagons.

Its solidity is found by multiplying the area of one of the pentagons by 12, and then this product by one-third of the distance of the face from the centre of the dodecahedron, which is the same with the centre of the circumscribing sphere.

The side of a dodecahedron, inscribed in a sphere, is the greater part of the side of a cube, inscribed in the same sphere, cut into extreme and mean proportion. If the diameter of the sphere be 1.0000, the side of the dodecahedron, inscribed in it, will be .35682 nearly.

All dodecahedrons are similar, and are to one another as the cubes of their sides; their surfaces are also similar, and therefore they are as the squares of their sides; whence as .509282 is to 10.51462, so is the square of the side of any dodecahedron to the superficies thereof; and as .3637 is to 2.78516, so is the cube of the side of any dodecahedron to the solidity of it.

DODECANDRIA, the name of the 11th class in Linnæus's sexual system, consisting of plants with hermaphrodite flowers, that, according to the title, have twelve stamina. This class, however, is not limited with respect to the number of stamina. Many genera have sixteen, eighteen, and even nineteen stamina: the essential character seems to be, that, in the class in question, the stamina, however numerous, are inserted into the receptacle:

whereas in the next class, icosandria, which is as little determined in point of number as the present, they are attached to the inside of the calyx, or flower-cup.

DODECAS, a genus of the trigynia order, in the dodecandria class of plants. The calyx is half-quadrifid, having the corolla above; the corolla quinquefid; the capsule unilocular, conjoined with the calyx. There is but one species, a shrub of Surinam.

DODECATHEON, a genus of the monogynia order, in the petandria class of plants, and in the natural method ranking under the 21st order, preciæ. The corolla is verticillated and reflexed; the stamina placed in the tube; the capsule unilocular and oblong. There is one species, the D. media, a beautiful perennial plant, a native of Virginia, but sufficiently hardy to bear our climate.

DODO. See Didus.

DODONÆA, a genus of plants of the octandria monogynia class: it has no corolla; the fruit is a roundish trilocular capsule, with prominent inflated angles, containing solitary seeds. There are two species.

DODRANS, in antiquity, three-fourths of the as. See As. and Coins.

DOG, in zoology. See Canis.

DOGS. The owner of a dog is bound to muzzle him if mischievous, but not otherwise; and if a man keep a dog that is known to bite cattle, &c. if after notice given to him of it, his dog shall do any hurt, the master shall answer for it.

The duty on dogs. The act 36 G. III. contains the following provisions:

1. That the duty shall not extend to dogs not six months old, the proof of which is to be on the owner, on an appeal to the commissioners.

2. If any person shall be desirous of compounding for the number of hounds by him kept, and shall give notice thereof to the collector, and shall pay within thirty days after April 5, yearly the sum of 30*l*., such person shall not be liable to be assessed in respect of any hounds by him kept in the preceding year: and if they are kept in two or more parishes, he shall give notice in which parish such composition is intended to be made.

By 42 Geo. III. cap. 17, any person keeping two or more dogs shall pay annually for every greyhound, pointer, setting dogs of whatsoever description or denomination, spaniel, lurcher, and terrier, and for every dog above one, whatever the same be, the sum of 10*s*.

And for any dog (not being a greyhound, hound, setting-dog, spaniel, lurchers, &c.) kept by or for use of any person inhabiting a dwelling-house assessed to any of the duties on houses, windows, or lights, where one such dog and no more shall be kept by or for the use of such person, the annual sum of 6*s*.

Dog's-bane. See Apocynum.

DOGE, formerly the chief magistrate in the republics of Venice and Genoa; but now, like many other venerable relics of ancient grandeur, absorbed in the modern Gothicism and tyranny of the abominable French revolution.

DOGMATISTS, a sect of ancient physicians, of which Hippocrates was the first author. They are also called logicians, from their using the rules of logic in subjects of their profession. They laid down definitions and divisions, reducing diseases to certain genera, and those genera to species, and furnishing remedies for them all; supposing principles, drawing conclusions, and applying those principles and conclusions to particular diseases under consideration: in which sense the dogmatisics stand contradistinguished from empires and methodists. They reject all medicinal virtues that they think not reducible to manifest qualities: but Galen has long ago observed of such men, that they must either deny plain matter of fact, or assign but very poor reasons and causes of many effects they pretend to explain.

DOLE, in our ancient customs, signified a part or portion, most commonly, of a meadow, where several persons have shares. It also still signifies a distribution or dealing of alms, or a liberal gift made by a great man to the people.

Dole, in the law of Scotland, is used for malevolent intention. This, which implies deceit, as well as dolum, in the civil law, whence it is taken, is an essential ingredient to constitute an action criminal. In crimes wherein the will, not the event, must be regarded, no negligence can equal dole, unless the negligence be so extremely supine as not to be conceivable without implying dole. Under this term are comprehended the vices and errors of the will, which are immediately productive of the criminal fact, though not premeditated, but the effect of sudden passion. In this respect dole differs from what the English law calls malice prepense.

DOLICHOS, a genus of the decandria order, in the diadelphia class of plants; and in the natural method ranking under the 32d order, papilionaceæ. The basis of the vexillum has two callous knobs, oblong, parallel, and compressing the alæ below. There are 38 species, the most remarkable of which are: 1. The lablab, with a winding stalk, is a native of warm climates, where it is frequently cultivated for the table. Mr. Hasselquist informs us, that it is cultivated in the Egyptian gardens, but is not a native of that country. The Egyptians make pleasant arbours with it in their houses and gardens, by supporting the stem and leading it where they think proper. They not only supported it with sticks and wood, but tie it with cords, by which means the leaves form an excellent covering, and afford an agreeable shade in sultry weather. 2. The soja, a native of Japan, where it is termed daidsu; and, from its excellence, mame; that is, "the legumen or pod," by way of eminence. It grows with an erect, slender, and hairy stalk, to the height of about four feet. The leaves are like those of the garden kidney-bean. The flowers are of a blueish white, and produced from the bosom of the leaves, and succeeded by bristly hanging pods resembling those of the yellow lupin, which commonly contain two, sometimes three, large white seeds. There is a variety of this kind, with a small black fruit, which was once employed in medicine. Kempfer affirms, that the seeds of this give relief in the asthma. This legumen is doubly useful in the Japanese kitchens. It serves for the preparation of a substance named miso, that is used as butter; and likewise a pickle celebrated among them, and frequent also at our own tables, under the name of sooju or soy. To make the first, they take a measure of the beans produced by the plant: after boiling them to a proper degree of softness, they beat them into a paste;

incorporating with it a large quantity of common salt. They then add a certain preparation of rice named koos; and having formed the whole into a mass, remove it into a wooden vessel, and, in about two months, it is fit for use. The koos gives it a grateful taste; and the preparing of it, like the polenta of the Germans, requires some experience. To make sooju or soy, they take equal quantities of the same beans boiled, and of muggi, that is, barley or wheat roughly ground, and of common salt. Having properly mixed the beans with the pounded corn, they keep it covered in a warm place, in order to ferment; then putting the mass into a pot, they cover it with the salt, pouring over the whole two measures and a half of water. This they frequently stir for two or three months, at the end of which time, they filtrate and express the mass, and preserve the liquor in wooden vessels. The older it is, the better and the clearer; and if made of wheat, it is the blacker. 3. The pruriens, or cow-itch, is also a native of warm climates. It has a fibrous root, and an herbaceous climbing stalk, which is naked, dividing into a great number of branches; and rises to a great height when properly supported. The leaves are alternate and trilobate, rising from the stem and branches about 12 inches distant from each other. The foot-stalk is cylindrical, from 6 to 14 inches long. From the axilla of the leaf descends a pendulous solitary spike, from 6 to 14 inches long, covered with long blood-coloured papilionaceous flowers, rising by threes in a double alternate manner from small fleshy protuberances, each of which is a short pedunculus of three flowers. These are succeeded by leguminous, coriaceous pods, four or five inches long, crooked like an italic *f*; densely covered with sharp hairs, which penetrate the skin, and cause great itching. This will grow in any soil in those countries where it is a native: but it is generally eradicated from all cultivated grounds; because the hairs from the pods fly with the winds, and torment every animal they happen to touch. If it was not for this mischievous quality, the beauty of its flowers would entitle it to a place in the best gardens. It flowers in the cool months, from September to March, according to the situation. The spiculæ, or sharp hairs, of this plant, have been long used in South America in case of worms; and have of late been frequently, and, as some writers have said, succesfully employed in Britain for the like purpose. The spiculæ of one pod mixed with syrup or molasses, and taken in the morning fasting, is a dose for an adult. 4. The dolichos lignosus is a handsome flowering shrub, introduced into our greenhouses, and easily propagated from seed, which it perfects in this country.

DOLIOCARPUS, a genus of the polyandria monogynia class and order. The calyx is five-leaved; corolla three-petalled, plaited; stigma subtrifid; berry globular, crowned with the style, one-celled, two-seeded. There are three species, shrubs of Guiana.

DOLPHIN. See DELPHINUS.

DOMBEYA, a genus of the class and order diœcia monadelphia. The male, calyx of the ament. scales; corolla none; anthers 10 and 12, without filaments. Female, calyx ament. with many germs; corolla none; stigma bivalve, unequal; seeds many, in a roundish strobile. There is one species, a tree of Chili.

DOME. See ARCHITECTURE.

DOMESDAY, is a very ancient record, made in William the Conqueror's time, and now remaining in the exchequer, fair and legible, consisting of two volumes, containing a survey of all the lands in England. It was begun by five justices, assigned for that purpose in each county, in the year 1081, and finished in 1086.

It is generally known, that the question whether lands are ancient demense or not, is to be decided by the Domesday-book of William the Conqueror; whence there is no appeal. And it is a book of that authority, that even the Conqueror himself submitted in some cases, wherein he was concerned, to be determined by it.

DOMESTIC, in antiquity, was a particular officer in the court of Constantinople.

According to some this office was one entrusted to manage affairs of importance: others say the Greek domestici were the same with the Roman comites; and that they began first to be used when count became a dignity: domestics therefore were such as served the prince in the administration of affairs, as well those of the family as the affairs of justice and the church.

DOMINANT OF A MODE, in music, is that sound which makes a fifth to the final, or tonic.

DOMINICAL LETTER, in chronology, is that letter of the alphabet which points out in the calendar the Sundays throughout the year, thence also called Sunday-letter. The distribution of days into weeks is made by the seven first letters of the alphabet A, B, C, D, E, F, G, beginning, at the first of January, to place the letter A; to the second of January B is joined; to the third C; and so on to the seventh, where G is figured: and then again beginning with A, which is placed at the eighth day, B will be at the ninth, C at the tenth, and so continually repeating the series of these seven letters, each day of the year has one of them in the calendar. By this means the last of December has the letter A joined to it, for if the 365 days, which are in the year, are divided by seven, we shall have 52 weeks, and one day over. If there had been no day over, all the years would constantly begin on the same day of the week, and each day of a month would constantly have fallen on the same day of the week; but now, since, besides the 52 weeks in the year, there is one day more, it happens, that on whatever day of the week the year begins, it ends upon the same day, and the next year begins with the following day.

The letters being ranked in this order, that letter which answers to the first Sunday of January, in a common year, will show all the Sundays throughout the year, and to whatever days in the rest of the months, that letter is put, these days are all Sundays. If the first day of January be on Sunday, the next year will begin on Monday, and the Sunday will fall on the seventh day, to which is annexed the letter G, which therefore will be the Sunday letter for that year: the next year beginning on Tuesday, the first Sunday will fall on the sixth of January, to which is adjoined the letter F, which is the Sunday letter for that year; and in the same manner, for the next following, the dominical letter will be E; and so on. By this means the Sunday letters will go on in a retrograde order, viz. G, F, E, D, C, B, A. But because every fourth year consists of 366 days, the series of letters will be interrupted, and the order will not

curn till twenty-eight years, or four times seven; and hence arises the cycle of 28 years.

Thus, if in a leap year the first of January is Sunday, and consequently the dominical letter A, the twenty-fourth day of February will fall on a Friday, and the twenty-fifth on a Saturday; and since both these days are marked in the calendar with the letter F, the following day, which is Sunday, will be marked with G, which letter will mark out all the Sundays, and consequently be the dominical letter, the remaining part of the year; and hence it is that every leap year has two dominical letters, the first of which serves from the beginning of the year to the twenty-fourth or twenty-fifth day of February, and then the other takes place and serves for the rest of the year.

The intercalary day is placed between the twenty-third and twenty-fourth days of February, and so makes two twenty-fourths of February, which in the calendar are esteemed one and the same day, and have the same letter affixed to them; but by our way of reckoning they are called the twenty-fourth and twenty-fifth days of February.

For finding the dominical letters, reject the figures or cyphers to the place of hundreds in the given year; divide the remaining figures or cyphers by 4; from this quotient subtract 1, and this number subtract from the hundred years; and then this last remainder taken from the least number of sevens possible, leaves a number which must be added to the year and its fourth, in order to find the dominical letter. Example: what will be the dominical letter for the year 1842? This question, by the above rule, will be solved in the following manner: 18÷4=4; from which subtracting 1, and the remainder 3 taken from 18, gives 15, which being subtracted from 21, the nearest sevens, gives 6, the number to be added. Then to the given year 1842, add its fourth part 460, and the number found 6, the sum is 2308; which being divided by 7, gives 329 for the quotient, and the remainder is 5; which taken from 7, leaves 2, the index of the letter B, the dominical letter required. By the same mode we find that F is the dominical letter for the present year, 1816.

DOMINICANS, an order of religious, called, in France, jacobins, and, in England, black friars, or preaching friars. This order, founded by St. Dominic, a native of Spain, was approved by Innocent III. in 1215, and confirmed by a bull of Honorius III. in 1216. The design of their institution was, to preach the gospel, convert heretics, defend the faith, and propagate christianity. They embraced the rule of St. Augustine, to which they added statutes and constitutions, which had formerly been observed by the Carthusians. The principal articles enjoined perpetual silence, abstinence from flesh at all times, wearing of woollen, rigorous poverty, and several other austerities. This order has spread into all the parts of the world. It has produced a great number of martyrs, confessors, bishops; and they reckon three popes, sixty cardinals, one hundred and fifty archbishops, and eight hundred bishops of their order, besides the masters of the sacred palace, who have always been dominicans. The nuns, or sisters of this order, owe their foundation to St. Dominic himself, who built a monastery at Prouilles, where poor maids might be brought up and supplied with all necessaries for their subsistence. The habit of these religious was a white robe, a tawny mantle, and a black veil. Their founder obliged them to work at certain hours of the day, and particularly to spin yarn and flax to make their own linen.

DONATIA, a genus of the trigynia order, in the triandria class of plants. The calyx is a triphyllous perianthium, with short subulated leaves standing at a distance from one another. The corolla has from eight to ten petals of an oblong linear shape, twice as long as the calyx. The stamina are three subulated filaments the length of the calyx; the antheræ roundish, didymous, and two-lobed at the base. There is one species.

DONATION, an act whereby a person transfers to another either the property or the use of something, as a free gift. In order to be valid, it supposes a capacity both in the donor and donee, and requires consent, acceptance, and delivery; and, by the French law, also registry. Civilians distinguish donation into pure and conditional. Donatio pura is when one gives a thing with an intention that it become immediately the property of the donee, never to revert to the donor; and this from no other motive than his generosity. Donatio conditionalis is when one gives a thing with an intention that it become the property of the donee, upon performing some condition stipulated.

DONATISTS, christians in Africa, who took their name from their leader Donatus. A secret hatred against Cæcilian, elected bishop of Carthage about the year 311, excited Donatus to form this sect. He accused Cæcilian of having delivered up the sacred books to the pagans, and pretended that his election was void, and all his adherents heretics. He taught that baptism administered by heretics was null, that every church but the African was become prostituted, and that he was to be the restorer of religion. Some accuse the Donatists of Arianism. Constantius and Honorius made laws for their banishment, and Theodosius and Honorius condemned them to grievous mulcts.

DONATIVE, a gratuity or present made to any person. Donative, among the Romans, was properly a gift made to the soldiers, as congiarium was that made to the people. Salmasius says, the common and legitimate rate of a donative was three pieces of gold per head; and Casaubon observes, that the legal donative was 20,000 denarii; and that it was not customary to give less, especially to the prætorian soldiers; that the centurions had double, and the tribunes, &c. more in proportion.

DONATIVE, in the canon law, is a benefice given by the patron to a priest, without presentation to the ordinary, and without institution or induction. The king may found a church or chapel, and exempt it from the jurisdiction of the ordinary. He may also, by his letters patent, grant licence to a common person to found such a church, and ordain it to be made donative. The resignation of a donative must be to the donor or patron, nor may the ordinary visit the same, but the patron by commissioners appointed by him. There can be no lapse of this benefice, though the bishop may compel such patron to nominate a clerk by ecclesiastical censures; and the clerk must be qualified as other clerks of churches are.

DONAX, a genus of insects belonging to the order of vermes testacea. It is an animal of the oyster kind; and the shell has two valves, with a very obtuse margin in the fore part. There are 10 species, principally distinguished by the figure of their shells. See Plate Nat. Hist. fig. 172.

DONJON, in fortification, signifies a strong tower, or redoubt of a fortress, whither the garrison may retreat, in case of necessity, and capitulate with greater advantage.

DONOR, in law, the person who gives lands or tenements to another in tail, &c. as he to whom such lands, &c. are given is the donee.

DORÆNA, a genus of the pentandria monogynia class and order. The cor. is five-cleft; stigma emarginate; caps. one-celled. There is one species, a dwarf tree about six feet high, a native of Japan.

DORIC ORDER, in architecture, the second of the five orders, being that between the Tuscan and Ionic. See ARCHITECTURE.

DORIC DIALECT, in grammar, one of the five dialects, or manners of speaking, which were principally in use among the Greeks. It was first used by the Lacedemonians, particularly those of Argos; afterwards it passed into Epirus, Lybia, Sicily, and the islands of Rhodes, Crete, &c. According to the Doric dialect, the vowels η, ε, ο, ω, are changed into α; the dipthong ει into α or αι; and the consonants β into γ; ζ into σδ; η and ς into τ; τ and ρ into κ; λ with a τ or Θ following it, into ν. Thus for φημη, τρεχω, κλειδας, βλεφαρα, &c. they say φαμα, τραχω, κλαδος, γλεφαρα, &c. They likewise change κ into ω, as λογω for λογκ; also εΘ for ευς, as βασιλεΘ for βασιλεΘ; εα, αι, and αει, into η, as κρης for κρεας, ιγελης for ιγελαις, and γελης for γελαις; with other transmutations of the like nature.

DORIC MODE, in music, the first of the authentic modes of the ancients; its character is to be severe, tempered with gravity and joy; and is proper upon religious occasions, as also to be used in war.

DORIS, a genus of insects, belonging to the order of vermes testacea. The body is oblong, flat beneath, creeping: mouth placed below: vent behind surrounded with a fringe: two feelers, retractile. There are several species. The argo, or lemon doris, has an oval body, convex, marked with numerous punctures, of a lemon-colour, the vent beset with elegant ramifications. It inhabits different parts of our seas, and is properly called the sea-lemon. There are four species.

DORMANT, in heraldry, is used for the posture of a lion, or any other beast, lying along in a sleeping attitude, with the head on the fore paws; by which it is distinguished from the couchant, where though the beast is lying, yet he holds up his head.

DORMOUSE, in zoology. See MUS, and SCIURUS.

DORONICUM, LEOPARD'S BANE; a genus of polygamia superflua order, in the syngenesia class of plants; and in the natural method ranking under the 49th order, compositæ. The receptacle is naked, the pappus simple; the scales of the calyx in a double row, longer than the disc. The seeds of the radius naked without any pappus. There are three species; of which the only one worthy of notice is the pardalianches, with obtuse heart-shaped leaves. It grows naturally in Hungary, and on the Helvetian mountains; but is frequently preserved in the English gardens. It has thick fleshy roots, which divide into many knobs or knees, sending out strong fleshy fibres which penetrate deep into the ground; from these arise in the spring a cluster of heart-shaped leaves, which are hairy, and stand upon foot-stalks: between these arise the flowerstalks, which are channelled and hairy, near three feet high, putting out one or two smaller stalks from the side. Each stalk is terminated by one large yellow flower. The plant multiplies very fast by its spreading roots: and the seeds, if permitted to scatter, will produce plants wherever they happen to fall; so that it very soon becomes a weed in the places where it is once established. It loves a moist soil and shady situation. The roots were formerly used in medicine, but their operation was found so violent that they are now entirely laid aside.

DORSAL MUSCLES are the muscles of the back and loins, which are for the most part common.

DORSIFEROUS PLANTS, among botanists, such as are of the capillary kind, without stalks, and which bear their seeds on the back side of their leaves.

DORSTENIA, CONTRAYERVA; a genus of the monogynia order, in the tetrandia class of plants; and in the natural method ranking under the 53d order, scabridæ. The receptacle is common, monophyllous, and carnous; the seeds lying singly in the carnous substance. There are eight species, all of them low herbaceous plants, growing in the warm countries of America and China. The root is used in medicine, under the name of contrayerva. It is full of knots; an inch or two in length; about half an inch thick; externally of a reddish-brown colour, and pale within; long, tough, slender fibres shoot out from all sides of it, which are generally loaded with small round knots. The root has a peculiar kind of aromatic smell, and a somewhat astringent, warm, bitterish taste, with a light and sweetish kind of acrimony when chewed. The fibres have little taste or smell; the tuberous part, therefore, should only be chosen. Contrayerva is indisputably a good and useful diaphoretic. Its virtues are extracted both by water and rectified spirit, and do not arise by evaporation with either. The plants cannot be propagated in this country without the greatest difficulty. See Plate L. Nat. Hist. fig. 173.

DORSUM, BACK. See ANATOMY.

DORYPHORI, in antiquity, an appellation given to the life-guard men of the Roman emperors.

DOSITHEANS, in church-history, a sect among the Hebrews, being one of the branches of the Samaritans. They abstained from eating any creature that had life, and were so superstitious in keeping the sabbath, that they remained in the same place and posture wherein that day surprised them, without stirring till the next day. They married but once, and a great number never married. Dositheus, their founder, being dissatisfied among the Jews, retired to the Samaritans, who were reputed heretics, and invented another sect; and, to make it more authentic, he went into a cave, where, by too long abstinence, he killed himself. The name of Dositheans was also given to some of the disciples of Simon Magus.

DOSSER, in military matters, a sort of basket, car-

ried on the shoulders of men, used in carrying the overplus earth from one part of a fortification to another, where it is wanted.

DOSSIL, in surgery, lint made into a cylindric form, used in dressing a disordered part.

DOTE ASSIGNANDA, in law, a writ that formerly lay for a widow, on its being found by office, that the king's tenant was seized with lands in fee or tail at the time of his death, and that he held of the king in chief, &c. in which case the widow was to come into the court of chancery, and there make oath that she would not marry without the king's leave; upon which she had this writ to the escheator, to assign her dower.

DOTE UNDE NIHIL HABET, a writ of dower which the widow may have against a person that bought land of her husband in his life-time, whereof he was seized in fee simple or fee tail, and of which she is endowable.

DOUBLE-CAST, in husbandry, a term used by the farmers for that method of sowing that does not dispense the necessary quantity of seed for a piece of land at one sowing, but requires going over every place twice. See HUSBANDRY.

DOUBLE *horizontal dial*, one with a double gnomon, one of which points out the hour on the outward circle, and the other shows the hour upon the sterographic projection drawn upon it. This dial not only finds the meridian hour, &c. but shows the sun's place, rising and setting, declination, amplitude, altitude, and azimuth, with many other useful propositions.

DOUBLE LETTER, in grammar, a letter which has the force and effect of two. The Greeks have three of these, viz. Z Ξ, Ψ; the Latins have two X and Z; and most of the modern languages have the same.

DOUBLE PLEA, in law, is where the defendant in a suit alleges two several matters in bar of the plaintiff's action, when one of them is sufficient. This is not admitted in common law. Thus, when a person pleads several things, the one having no dependance upon the other, such plea is accounted double, and will not be admitted; but where the things pleaded, mutually depend on each other, and the party cannot have the last plea without the first, there the whole shall be received.

DOUBLE QUARREL, is a complaint made by any clerk, or other, to the archbishop of the province against an ordinary, for delaying justice in any cause ecclesiastical; as to give sentence, to institute a clerk presented, or the like: the effect whereof is, that the archbishop taking notice of such delay, directs his letters under his authentic seal, to all and singular clerks of his province, thereby commanding and authorising them, and every of them, to admonish the said ordinary, within a certain time, nine days, to do the justice required, or otherwise to cite them to appear before him the said archbishop, or his official, at a day in the said letters prefixed, and there to allege the cause of his delay. And lastly, to intimate to the said ordinary, that if he neither perform the thing enjoined, nor appear at the day assigned, he himself will, without delay, proceed to perform the justice required; and this seems to be termed a double quarrel, because it is most commonly made both against the judge and him at whose petition justice is delayed. Clark's Prax. Tit. 84, 5.

DOUBLES, nearly the same as letters patent. Stat. 14 H. VI.

DOUBLETS, a game on dice within tables: the men, which are only fifteen, being placed thus; upon the sice, cinque, and quarter points, there stand three men apiece; and upon the trey, duce, and ace, only two. He that throws highest has the benefit of throwing first, and what he throws he lays down, and so does the other: what the one throws, and has not, the other lays down for him, but to his own account; and thus they do till all the men are down, and then they bear. He that is down first bears first, and will doubtless win the game, if the other throws not doublets to overtake him; which he is sure to do, since he advances or bears as many as the doublets make, viz. eight for two fours.

DOUBLING, in the military art, is the putting two ranks or files of soldiers into one. Thus, when the word of command is, double your ranks, the second, fourth, and sixth ranks march into the first, third, and fifth, so that the six ranks are reduced to three, and the intervals between the ranks become double what they were before. To double by half-files, is when the fourth, fifth, and sixth ranks march up to double the first, second, and third, or the contrary. To double the files to the right, is when every other file faces to the right, and marches into the next file to it, so that the six ranks are turned into twelve, and every file is twelve deep. To double the files to the left, is when every other file faces to the left, and marches into the next. In doubling the files, the distance between the files becomes double.

DOVE-TAILING, in carpentry, is the manner of fastening boards together by letting one piece into another, in the form of the tail of a dove. The dovetail is the strongest of the assemblages or jointings, because the tenon, or piece of wood which is put into the other, goes widening to the extreme, so that it cannot be drawn out again, because the extreme or tip is larger than the hole.

DOUGLASSIA, a genus of the class and order polyadelphia polyandria. The cal. is half six-cleft; cor. none; nect. six; filam. none; germ. superior; stigma six-cleft; berry ovate, one-celled, seed one. There is one species, a shrub of Guiana.

DOULEIA, in Grecian antiquity, a kind of punishment among the Athenians, by which the criminal was reduced to the condition of a slave. It never was inflicted but upon the ἄτιμοι, sojourners, and freed servants.

DOWER, the portion which a widow has of the lands of her husband, after his decease, for the sustenance of herself, and the education of her children.

To the consummation of dower, three things are necessary, viz. marriage, seisin, and the husband's death.

There were formerly five kinds of dower in England, viz. 1. Dower by the common law. 2. Dower by custom. 3. Dower ad ostium ecclesiæ. 4. Dower ex assensu patris, and 5. Dower de la plus belle. But of all these kinds of dower, only the first two are now in use.

Dower by the common law, is a third part of such lands or tenements whereof the husband was sole seized in fee-simple, or fee-tail, during the marriage, which the wife is to enjoy during her life; for which there lies

a writ of dower. See DISTRIBUTION OF INTESTATE'S EFFECTS.

Dower by custom varies according to the custom and usage of the place, and is to be governed accordingly; and where such custom prevails, the wife cannot wave the provision thereby made for her, and claim her thirds at common law, because all customs are equally ancient with the common law itself. Co. Lit. 39 b.

Dower ad ostium ecclesiæ, is where a man of full age, seized of lands in fee, after marriage, endows his wife at the church-door of a moiety, a third, or other part of his lands, declaring them in certainty; in which case, after her husband's death, she may enter into such lands without any other assignment, because the solemn assignment at the church-door is equivalent to the assignment in pais by metes and bounds; but this assignment cannot be made before marriage, because *before*, she is not entitled to dower. Lit. sect. 39.

Dower ex assensu patris, is where the father is seized of land in fee; and his son and heir apparent *after* marriage endows his wife by his father's assent, ad ostium ecclesiæ, of a certain quantity of them; in which case, after the death of the son, his wife may enter into such parcel without any other assignment, though the father be living; but this assent of the father's must be by deed, because his estate is to be charged *in futuro*, and this may likewise be of more than a third part. Co. Lit. 35, 36.

The dowers ad ostium ecclesiæ, or ex assensu patris, if the wife enter and assent to them, are a good bar of her in common law; but she may, if she will, wave them, and claim her dower at common law, because being made after marriage, she is not bound by them. Br. 97.

DOWER *de la plus belle*, is where there is a guardian in chivalry, and the wife occupies lands of the heir as guardian in soccage: if the wife bring a writ of dower against such guardian in chivalry, he may show this matter, and pray that the wife may be endowed *de la plus belle* of the tenements in soccage, and it will be adjudged accordingly; and the reason of this endowment was to prevent the dismembering of the lands holden in chivalry, which are pro bono publico, and for the defence of the realm. Lit. sect. 48.

After judgment given, the wife may take her neighbours, and in their presence endow herself of the plus belle, or fairest part, of the tenements which she has in soccage, for her life. Lit. sect. 48.

DOWN, the fine feathers from the breasts of several birds, particularly of the duck kind. That of the eider duck (see ANAS) is the most valuable. These birds pluck it from their breasts, and line their nests with it. We are told that the quantity of down found in one nest more than filled the crown of a hat, yet weighed no more than three quarters of an ounce. Three pounds of this down may be compressed into a space scarcely larger than one's fist; yet is afterwards so dilatable as to fill a quilt five feet square. That found in the nests is most valued, and termed *live down;* it is infinitely more elastic than that plucked from the dead bird, which is little esteemed in Iceland. The best sort is sold at 45 fish per pound when cleansed, and at 16 when not cleansed. There are generally exported every year, on the company's account, 1500 or 2000 lb. of both sorts, exclusive of what is privately exported by foreigners. In 1750, the Iceland company sold as much in quantity of this article as amounted to 3745 banco dollars, besides what was sent directly to Gluckstadt.

DOWNS, a bank or elevation of sand, which the sea gathers and forms along its shores, and which serves it as a barrier.

DOWRY, in ancient time, applied to that which the wife brings her husband in marriage, otherwise called maritagium, or marriage-goods; but these are termed more properly goods given in marriage, and the marriage-portion. 1 Inst. 31.

DOWRY, is used in a monastic sense for a sum of money given along with a maid, upon entering her in some religious order. In France, the dowry of persons entering a monastery, to make profession of a religious life, was limited by law. That given upon entering a monastery of Carmelites, Ursulines, and others not regularly founded, but established since the year 1600, by letters patent, did not exceed the sum of 8000 livres in towns where parliaments were held, nor 6000 in other places.

DRABA, a genus of the siliculosa order, in the tetradynamia class of plants, and in the natural method ranking under the 39th order, siliquosæ. The silicula is entire, and oval-oblong; with the valves a little plane, parallel to the partition; there is no style. There are nine species; of which the only one worthy of notice is the verna, or early whitlow-grass. It has naked stalks, with leaves a little serrated. The blossoms are white, and at night the flowers hang down. It grows on old walls and dry banks. It is one of the earliest-flowering plants we have, and is good to eat as a salad. Goats, sheep, and horses eat it; cows are not fond of it; swine refuse it.

DRABLER, in the sea language, a small sail in a ship, which is the same to a bonnet that a bonnet is to a course, and is only used when the course and bonnet are too shoal to clothe the mast.

DRABLING, in angling, is a method of catching barbels. Take a strong line of six yards, which, before you fasten to your rod, must be put through a piece of lead, that if the fish bite it may slip to and fro, and that the water may something move it on the ground. Bait with a lob-worm well secured, that by its motion the barbel may be enticed into the danger without suspicion. The best places are in running water near piles, or under wooden bridges, supported with oaks floated and slimy.

DRABS, in the salt-works, a kind of wooden boxes for holding the salt when taken out of the boiling-pan. The bottoms of them are made shelving or inclining forwards, that the briny moisture of the salt may drain off.

DRACÆNA, a genus of the monogynia order, in the hexandria class of plants. The corolla is sexpartite and erect; the filaments a little thicker about the middle; the berry trilocular and monospermous. There are 14 species, most of them having the habit of the palms, and one of them at least (the D. draco, which is a magnificent plant, or rather tree) affording a red powder, like the eastern dragon's-blood. See that article.

DRACHM, a Grecian coin, of the value of 14 ots.

Drachm is also a weight used by our physicians; containing just sixty grains, three scruples, or the eighth part of an ounce.

DRACO, the dragon, in zoology, a genus belonging to the order of amphibia reptilia; the characters of which are these: it has four legs, a cylindrical tail, and two membranaceous wings, radiated like the fins of a fish, by which he is enabled to fly, but not to any great distance at a time. There are two species.

1. The volans, or flying-dragon, with the wings entirely distinct from the fore-legs. It is found in Africa and the East Indies.

2. The præpos, with the wings fixed to the fore-legs. It is a native of America. They are both harmless little creatures, and feed upon flies, ants, and small insects. See Plate L. Nat. Hist. fig. 174.

Draco volans, in meteorology, a fiery exhalation, frequent in marshy and cold countries. It is most common in summer; and though principally seen playing near the banks of rivers, or in boggy places, yet sometimes mounts up to a considerable height in the air, to the no small terror of the amazed beholders; its appearance being that of an oblong, sometimes roundish, fiery body, with a long tail. It is entirely harmless, frequently sticking to the hands and clothes of people without injuring them in the least.

Draco, in astronomy, a constellation of the northern hemisphere, whose stars, according to Ptolemy, are 81; according to Tycho, 32; according to Hevelius, 40; according to Bayer, 33; and acoording to Mr. Flamsteed, 80. See Astronomy.

DRACOCEPHALUM, dragon's-head, a genus of the gymnospermia order, in the didynamia class of plants. The throat of the corolla is inflated, the upper lip concave. There are 15 species, most of them herbaceous, annual, or perennial plants, from 18 inches to three feet high, mostly with entire leaves and whorled spikes of small monopetalous and ringent flowers, of a blue, white, or purple colour. They are all easily propagated by seeds, which may be sown either in the spring or autumn; and after the plants are come up, they will require no other culture but to be kept clear from weeds. The D. canariense is well known by the name of balm of Gilead.

DRACONARIUS, in antiquity, dragon-bearer. Several nations, as the Persians, Parthians, Scythians, &c. bore dragons on their standards; whence the standards themselves were called *dracones*, dragons. The Romans borrowed the same custom from the Parthians; or, as Casaubon has it, from the Dacæ; or, as Codin, from the Assyrians. The Roman dracones were figures of dragons painted in red on their flags, as appears from Ammianus Marcellinus: but among the Persians and Parthians they were like the Roman eagles, figures in full relievo; so that the Romans were frequently deceived, and took them for real dragons. The soldier who bore the dragon or standard, was called by the Romans *draconarius*; and by the Greeks δρακοναριος and δρακοντιοφορος; for the emperors carried the custom with them to Constantinople.

DRACONTIUM, dragons, a genus of the polyandria order, in the gynandria class of plants, and in the natural method ranking under the first order, palmæ. The spatha is cymbiform, or shaped like a boat; the spadix covered all over; there is no calyx; there are five petals; the berries polyspermous. There are five species, all natives of the Indies. The only one which makes any appearance is the pentusum, with leaves having holes, and a climbing stalk. This is a native of most of the West India islands. It has trailing stalks, which put out roots at every joint, that fasten to the trunks of trees, walls, or any support which is near them, and by that means rise to the height of 25 or 30 feet. The leaves are placed alternately upon long footstalks: they are four or five inches long, two and a half broad, and have several oblong holes in each, which at first sight appear as if eaten by insects, but they are natural to the leaves. The flowers are produced at the top of the stalk, which always swells to a much larger size in that part than in any other: these are covered with an oblong spatha or hood of a whitish-green colour, which opens longitudinally on one side, and shows the pistil, which is closely covered with flowers of a pale yellow, inclining to white. This plant is easily propagated by cuttings, which if planted in pots filled with poor sandy earth, and plunged into a hot-bed, will soon put out roots; but the plants are so tender, that they must be preserved in a stove.

DRACUNCULI, in medicine, small long worms, which breed in the muscular parts of the arms and legs, called Guinea-worms.

This distemper is very common in Guinea, and principally among the natives: Kempfer found it also at Ormuz, upon the Persian Gulph, and likewise in Tartary. Dr. Tawne, in his Treatise on the Diseases of the West Indies, informs us, that this distemper is not so frequent any where as on the gold-coast, at Anamaboe, and Cormantyn. The worm is white, round, and uniform, very much resembling white round tape, or bobbin. It is lodged between the interstices and membranes of the muscles, where it insinuates itself, sometimes exceeding five ells in length. It occasions no great pain at the beginning; but at such times as it is ready to make its exit, the part adjoining to the extremity of the worm, where it attempts its exclusion, begins to swell, throb, and be inflamed: this generally happens about the ancle, leg, or thigh, and rarely higher.

The countries where this distemper is observed, are very hot and sultry, liable to great droughts, and the inhabitants make use of stagnating and corrupted water, in which it is very probable that the ova of these animalcula may be contained; for the white people who drink this water are obnoxious to the disease as well as the negroes.

The surgeons seldom attempt to extract this worm by making an incision; but as soon as they perceive the tumour rise to a competent bulk, they endeavour to bring it to a suppuration, with all convenient expedition; and then the head of the worm discovers itself, which they secure, by tying it to a bit of stick or cotton, that it may not draw itself up again: thus they continue to rool it round the stick, sometimes one inch, sometimes two or more, each day, taking great care not to break the worm, else it will be very difficult to recover the end of it again; and an abcess will be formed, not only at the suppurated part, but likewise through the whole wind-

ing of the muscles, where the dead putrifying worm remains, which generally occasions very obstinate ulcers. During the extraction of the worm, the patient should be plied with bitter aloetic and other anthelmintic medicines, in order to dislodge the worm the sooner from his tenement. When the worm is totally extracted, the remaining ulcer may be treated in the same manner as other common ulcers; nor does any farther inconvenience remain in the parts of which it had possession. This disease, simply considered, very rarely, if ever, proves mortal.

DRAG, in sea language, is a machine consisting of a sharp, square, iron ring, encircled with a net, and commonly used to take the wheel off from the platform or bottom of the decks.

DRAGOMAN, or Drogman, a term of general use through the East, for an interpreter whose office is to facilitate commerce between the orientals and occidentals. These are kept by the ambassadors of Christian nations residing at the Porte for this purpose. The word is formed from the Arabic *targeman* or *targiman*, of the verb *taragem*, he has interpreted. From *dragoman* the Italians formed *dragomano*, and, with a nearer relation to its Arabic etymology, *turcimanno;* whence the French and our *trucheman*, as well as dragoman and drogman.

DRAGON's *head and tail*, are the nodes of the planets, or the two points wherein the ecliptic is intersected by the orbits of the planets, and particularly that of the moon; making with it angles of five degrees and eighteen minutes. One of these points looks northward, the moon beginning then to have northward latitude; and the other southward, where she commences south. Thus her deviation from the ecliptic seems (according to the fancy of some) to make a figure like that of a dragon, whose belly is where she has the greatest latitude; the intersection representing the head and tail, from which resemblance the denomination arises. But it must be observed that these points abide not always in one place, but have a motion of their own in the zodiac and retrogradewise, three minutes eleven seconds per day, completing their circle in 18 years 225 days: so that the moon can be but twice in the ecliptic during her monthly period, but at all other times she will have a latitude or declination from the ecliptic. It is about these points of intersection that all eclipses happen. They are usually denoted by these characters, ☊ dragon's head, and ☋ dragon's tail.

Dragon, in zoology. See Draco.

Dragon's *blood*, a gummy resinous substance so called, which is brought from the East Indies, either in oval drops wrapped up in flag leaves, or in large masses composed of smaller tears. It is said to be obtained from the palmijuncus draco, the calamus rotang, the dracena draco, the pterocarpus draco, and several other vegetables. In the present practice of medicine, it is very little if at all used, either externally or internally. A solution of dragon's-blood in spirit of wine is used for staining marble, to which it gives a red tinge, which penetrates more or less deeply according to the heat of the marble during the time of application. But as it spreads at the same time that it sinks deep, for fine designs the marble should be cold. M. du Fay says, that by adding pitch to this solution the colour may be rendered deeper.

Dragon-fly. See Libellula.

Dragon-shell, in natural history, a name given by people curious in shells to a species of concamerated patella or limpet. This has a top very much bent, and is of an ash-colour on the outside, but of an elegant and bright flesh-colour within. It has been found sticking on the back of a tortoise, as the common limpets do on the sides of rocks, and some have been found affixed to large shells of the pinna marina.

DRAGONNE'E, in heraldry: a lion dragonne'e is where the upper half resembles a lion, the other half going off like the hinder part of a dragon. The same may be said of any other beast as well as a lion.

DRAGOON, in military affairs, a musqueteer mounted on horseback, who sometimes fights or marches on foot, as occasion requires. Menage derives the word dragoon from the latin *draconarius*, which in Vegetius is used to signify soldier. But it is more probably derived from the German *targen* or *dragen*, which signifies *to carry*, as being infantry carried on horseback. Dragoons are divided into brigades as the cavalry, and each regiment into troops, each troop having a captain, lieutenant, cornet, quarter-master, two serjeants, three corporals, and two drummers: some regiments have hautboys. They are very useful on any expedition that requires despatch; for they can keep pace with the cavalry, and do the duty of infantry. They encamp generally on the wings of the army, or at the passes leading to the camp; and sometimes they are brought to cover the general's quarters: they march in the front and rear of the army. The first regiment of dragoons raised in England was in 1681, and called the regiment of dragoons of North Britain. In battle or attacks they generally fight sword in hand after the first fire.

DRAGOONING, one of the methods used by papists for converting refractory heritics, and bringing them within the pale of the Romish church. The following method of dragooning the French protestants after the revocation of the edict of Nantes, under Louis XIV. is taken from a French work, translated in 1686. The troopers, soldiers, and dragoons, went into the protestants' houses, where they marred and defaced their household-stuff, broke their looking-glasses and other utensils and ornaments, let their wine run about their cellars, and threw about their corn and spoiled it. And as to those things which they could not destroy in this manner, such as furniture of beds, linen, wearing-apparel, plate, &c. they carried them to the market-place, and sold them to the Jesuits and other Roman-catholics. By these means the protestants in Montaubon alone were stripped of above a million of money. But this was not the worst. They turned the dinning-rooms of gentlemen into stables for their horses; and treated the owners of the houses where they quartered with the highest indignity and cruelty, lashing them about from one to another, day and night, without intermission, not suffering them to eat or drink; and when they began to sink under the fatigue and pains they had undergone, they laid them on a bed; and when they thought them somewhat recovered, made them rise, and repeated the

same tortures. When they saw the blood and sweat run down their faces and other parts of their bodies, they sluiced them with water; and putting over their heads kettle-drums turned upside down, they made a continual din upon them, till these unhappy creatures lost their senses. To recount all the ingenious cruelties exercised in the practice of dragooning by these religious savages, would curdle the blood of even the most insensible.

DRAGS, in the sea language, are whatever hangs over the ship in the sea, as shirts, coats, or the like; and boats when towed, or whatever else after this manner may hinder the ship's way when she sails, are called drags.

DRAINING, the art of clearing wet and boggy lands of their superfluous moisture, an art of the highest importance not only to the agriculture, but to the health of a country. It is only in modern times that the principles of this art have been well understood, and it seems yet susceptible of great improvement.

Land becomes charged with moisture from two causes: 1. From water collected in the higher grounds, and filtrating among the different beds of gravel and other porous materials, forming springs below, and flowing over the surface, or stagnating underneath it. 2. From rain or water lodging and becoming stagnant on the surface, from the clayey or impervious nature of the soil or superior statum. The first of their causes bogs, swamps, and morasses, and is the most difficult to be remedied.

It may be laid down as a maxim, that springs are formed in the bowels of the earth, by water percolating through the strata where they are of a porous texture, and it continues to descend till it meets with a stratum of clay that intercepts it in its course; where, being collected in large quantities, it is forced to seek a passage through the porous strata of sand, gravel, or rock, that may be above the clay, following the course of these strata till they approach the surface of the earth, or are interrupted by any obstacle which occasions the water to rise, thus forming springs, bogs, and the other phenomena of this nature; which being variously diversified in different circumstances, produce that variety of appearances in this respect that we often meet with.

This being the case, we may naturally conclude, that an abundant spring need never be expected in any country that is covered to a great depth with sand without any stratum of clay to force it upwards, as is the case in the sandy deserts of Arabia, and the immeasurable plains of Lybia: neither are we to expect abundant springs in any soil that consists of an uniform bed of clay from the surface to a great depth; for it must always be in some porous stratum that the water flows in abundance; and it can be made to flow horizontally in that, only when it is supported by a stratum of clay, or other substance that is equally impermeable by water. Hence the *rationale* of that rule so universally established in digging for wells, that if you begin with sand or gravel, &c. you need seldom hope to find water till you come to clay; and if you begin with clay, you can hope for none in abundance till you reach to sand, gravel, or rock.

It is necessary that the farmer should attend to this process of nature with care, as his success in draining bogs and every species of damp and spouting ground, will in a great measure depend upon his thorough knowledge of this, his acuteness in perceiving in every case the variations that may be occasioned by particular circumstances, and his skill in varying the plan of his operations according to these. As the variety of cases that may occur in this respect is very great, it would be a tedious task to enumerate the whole, and describe the particular method of treating each; we shall therefore content ourselves with enumerating a few particular cases to show in what manner the principles above-established may be applied to practice.

Let fig. 57, Plate XLIV. Miscel. represent a perpendicular section of a part of the earth, in which AB is the surface of the ground, beneath which are several strata of porous substances that allow the water to sink through them till it reaches the line CD, that is supposed to represent the upper surface of a solid bed of clay; above which lies a stratum of rock, sand, or gravel. In this case it is plain that when the water reaches the bed of clay, and can sink no farther, it must be there accumulated into a body; and seeking for itself a passage, it flows along the surface of the clay, among the sand or gravel, from D towards C; till at last it issues forth, at the opening A, a spring of pure water.

If the quantity of water that is accumulated between D and C is not very considerable, and the stratum of clay approaches near the surface; in that case the whole of it will issue by the opening at A, and the ground will remain dry both above and below it. But if the quantity of water is so great as to raise it to a considerable height in the bed of sand or gravel, and if that stratum of sand is not discontinued before it reaches the surface of the ground, the water, in this case, would not only issue at A, but would likewise ooze out in small streams through every part of the ground between A and *a*, forming a barren patch of wet sandy or gravelly ground upon the side of a declivity, which every attentive observer must have frequently met with.

To drain a piece of ground in this situation is perhaps the most unprofitable task that a farmer can engage in, not only because it is difficult to execute, but also because the soil that is gained is but of very little value. It is lucky, however, that patches of this kind are seldom of great breadth, although they sometimes run along the side of a declivity in a horizontal direction for a great length. The only effectual method of draining this kind of ground, is to open a ditch as high up as the highest of the springs at *a*, which should be of such a depth as not only to penetrate through the whole bed of sand or gravel, but also to sink so far into the bed of clay below, as to make a canal in it sufficiently large to contain and carry off the water. Such a ditch is represented by the dotted lines *aez:* but as the expense of making a ditch of such a depth as this would suppose, and of keeping it afterwards in repair, is very great, it is but in very few cases that this mode of draining would be advisable; and never, unless where the declivity happens to be so small as that a great surface is lost for little depth, as would have been the case here if the surface had extended in the direction of the dotted line *ad*.

But supposing that the stratum of clay, after approaching towards the surface at A, continued to keep at a little depth below ground; and that the soil which lay above it was of a sandy or spongy nature, so as to allow the

water to penetrate it easily; even supposing the quantity of water that flowed from D to C was but very inconsiderable, instead of rising out at the spring A, it would flow forward along the surface of the clay among the porous earth that forms the soil, so as to keep it constantly drenched with water, and of consequence render it of very little value.

Wetness arising from this cause is usually of much greater extent than the former; and as it admits of an easy cure, it ought not to be delayed; as a ditch of a very moderate depth opened at A, and carried through a part of the stratum of clay (as represented by the dotted lines A *kf*), would intercept and carry off the whole of the water, and render the field as dry as could be desired. It is, therefore, of very great consequence to the farmer accurately to distinguish between these two cases, so nearly allied to each other in appearance; and as this can be easiest done by boring, every one who has much ground of this kind ought to provide himself with a set of boring-irons, which he will likewise find use for on other occasions.

We might here enumerate a great variety of cases which might be reduced to the same head with the foregoing; but as any attentive reader may, after what has been said, be able easily to distinguish these, we shall only in general observe, that every soil of a soft and porous texture that lies upon a bed of hard clay, whatever its situation in other respects may be, will in some measure be subjected to this disease. And if it is upon a declivity of any considerable length, the undermost parts of the field will be much damaged by it, unless ditches are thrown up across the declivity at proper distances from one another, to intercept the water in its descent.

It may likewise be not improper here to observe, that in cases of this nature, unless where the soil is of a very great depth, the malady will always be increased by raising the ridges to a considerable height; as will appear evident by examining fig. 58. in which the line AB represents the surface of a field of this nature, and CD the surface of the bed of clay. Now if this field was raised into high ridges, as at FFF, so that the furrows EEE descended below the surface of the clay, it is plain that all the water that should sink through the middle of the ridge, would run along the surface of the clay till it came to the sides of the ridge LLLLLL, which would thus be kept continually soaked with water. Whereas, if the ground had been kept level, as in the part of the field from G to H, with open furrows H, at moderate distances from each other, the water would immediately sink to the clay, and be carried off by the furrows, so as to damage the soil far less than when the ridges are high. If the soil is so thin as that the plough can always touch the clay, the ridges ought to be made narrow and quite flat, as from G to H: but if there is a little greater depth of soil, then it ought to be raised into ridges of a moderate height, as from H to B, so as to allow the bottom of the furrow to reach the clay: but neither is this necessary where the soil is of any considerable depth.

Some industrious farmers having ground in this situation, have been at the very great expense of making a covered drain in each furrow. But, had they rightly understood the nature of the disease, they never would have thought of applying such a remedy, as must appear evident at first sight to those who examine the figure. The success was what might be expected from such a foolish undertaking.

These observations, it is hoped, will be sufficient as to the manner of treating wet, sandy, or porous soils. We now proceed to take notice of such as are of a stiff clayey nature, which are often very different in appearance, and require a different treatment, from these.

Suppose that the stratum of sand or gravel DC, fig. 59. should be discontinued, as at E, and that the stratum above it should be of a coherent clayey nature: in this case, the water that flowed towards E, being there pent in on every side, and being accumulated there in great quantities, it must at length force a passage for itself in some way; and pressing strongly upon the upper surface, if any one part is weaker than the rest, it there would burst forth and form a spring (as suppose at A). But if the texture of every part of this stratum was equally strong, the water would squeeze through many small crannies, and would ooze out in numberless places, as between A and F, so as to occasion that kind of wetness that is known by the name of a spouting clayey soil.

The cure, in this case, is much more easily effected than in any of the former; for if a ditch of a considerable size is opened, as at A, towards the lowermost side of the spouting ground, so deep as to penetrate through the upper stratum of clay, and reach to the gravel, the water will rise up through it at first with very great violence, but will gradually decrease as the pressure from the water behind is diminished; and when the whole of the water accumulated in this subterraneous reservoir is run off, there being no longer any pressure upon the clay above it, the whole soon becomes as dry as could be desired, and continues so ever afterwards, if the ditch is always kept open.

It will hardly be necessary in this place to put the farmer upon his guard to be particularly careful in his observations, that he may distinguish between the wetness which is produced from this cause, and that which proceeds from the cause before-mentioned: because the treatment that would cure the one would be of no use at all to the other. The attentive observer likewise will readily perceive, that if any field that is wet from this cause admits of being ploughed, it will be in equal danger of being hurt by being raised into high ridges with the other kind of damp ground before-mentioned. For as the depth of earth above the reservoir would be smaller in the deep furrows than any where else, there would be less resistance to the water in that place, so that it would rise there in greater abundance. And if, in this case, a farmer should dig a drain in each furrow, as a considerable quantity of water would rise into them, in some cases, the ground might be improved or even quite drained by it, especially if they should have accidentally reached the gravel in any one place, although at an expense much greater than was necessary. We take notice of this circumstance, in some measure to prevent the prejudice that some inattentive observers might entertain against what was said before of this method of draining, from their having accidentally seen some fields that may have been bettered by it.

Bogs are only a variety of this last-mentioned kind of wet ground, and therefore ought in general to be drain-

ed after the same manner with them. Clay is a substance that strongly resists the entrance of water into it; but when it is long drenched with it, it is, in process of time, in some measure dissolved by it, loses its firmness of texture and consistence, and becomes a sort of semifluid mass, which is called a bog; and as these are sometimes covered with a strong scurf of a particular kind of grass, with very matted roots, which is strong enough to bear a small weight without breaking, although it yields very much, it is in these circumstances called a shake-bog. But whatever is the nature of the bog, it is invariably occasioned by water being forced up through a bed of clay, as just now described, and dissolving or softening a part of it: we say only a part, because whatever may be the depth of the hog or swaggle, it generally has a partition of solid clay between it and the reservoir of water under it, whence it originally proceeds: for if this was not the case, and the quantity of water was considenable, it would meet with no sufficient resistance from the bog, and would issue through it with violence, and carry the whole semifluid mass along with it. But this would more inevitably be the case if there was a crust at the bottom of the bog, and if that crust should ever be broken, especially if the quantity of water under it was very considerable: and as it is probable that, in may cases of this sort, the water slowly dissolves more and more of this under-crust, we make no doubt that, in the revolution of many ages, a great many eruptions of this kind may have happened, although they may not have been deemed of importance enough to have the history of them transmitted to posterity. Of this kind, although formed of a different substance, we consider the flow of the Solway-moss in Northumberland to have been; which, upon the 16th of November 1771, burst its former boundaries, and poured forth a prodigious stream of semifluid matter, which in a short time covered several hundred acres of very fine arable ground. Nor will any one who is acquainted with the nature of moss, who knows its resemblance to clay in its quality of absorbing and retaining water, and its very easy diffusibility in it, be surprised at this; as, from all these properties, it is much better adapted for forming an extensive bog, and therefore in greater danger of producing an extensive devastation by an eruption of the water into it, than those that are formed of any kind of clay whatever.

If the bog or swampy ground is upon a declivity, the ditch ought to be carried across the field about the place where the lowest springs arise. But if the surface of the ground is level, or nearly so, as between A and B, fig. 60. and the springs break out in several places, *qqqqqq*, so as to form soft quagmires interspersed through the whole of the field, it will be of little consequence in what part the drain is opened; for if it is dug up so deep as to allow the water to rise in it with freedom, it will issue through that opening, and the field will be left perfectly dry.

But as it may frequently happen that the stratum of gravel is at a considerable depth beneath the surface of the earth, and as it may be sometimes even below the level of the place into which the drain must be emptied, it must sometimes be extremely difficult to make a ditch so deep as to reach the bed of sand or gravel. But it is lucky for us that this is not absolutely necessary in the present case; as a drain of two or three feet deep, as at D, will be equally effectual with one that should go to the gravel. All that is necessary in this case is, to sink pits (P) in the course of the drain, at a moderate distance from one another, which go so deep as to reach the gravel; for as the water there meets with no resistance, it readily flows out at these openings, and is carried off by the drain without being forced up through the earth, so that the ground is left entirely dry ever after.

Let it be carefully noted, that if you attempt to make your pit in one of these soft quaggy places where the water is found in great abundance, you will meet with very great difficulty in forming it; for as the substance of which it is composed is soft, it will always flow into the hole as fast as you dig it; on which account we should advise not to attempt to make the pit in the swaggle or shake-bog, but as near it in the solid earth as you conveniently can. However, if it is pretty firm, and of no great extent, it is sometimes practicable to make a pit in the soft bog at the driest time of the year. This soft quaggy ground has seldom been found above three or four feet deep, below which there is always found a stratum of hard tough clay, usually mixed with stones, and so firm that nothing but a mattock or pick-axe could penetrate it; and as this is comparatively so much drier than the ground above it, an inexperienced operator is very apt to imagine that this is the bottom that he is in search of. In digging through this stratum, you will frequently meet with small springs oozing out in all directions; some of them that might fill the tube of a small quill, and others so small as to be scarcely perceptible: but without regarding these, you must continue to dig on without intermission till you come to the main body of the reservoir, if we may so call it, that is contained in the rock, gravel, or sand, which you will generally find from two to four feet below the bottom of the swaggle, and which you will be in no danger of mistaking when you come to it; for if there has been no opening made before that in the field, as soon as you break the crust immediately above the gravel or rock, the water bursts forth like a torrent, and on some occasions rises like a jet-d'eau to a considerable height above the bottom of the ditch, and continues to flow off with great impetuosity for some time, till the pent-up water being drained off, the violent boiling up begins to subside, and the strength of the current to abate; and in a short time it flows gently out like an ordinary spring: allowing it to remain in this state, the quaggy earth begins to subside, and gradually becomes firmer and firmer every day; so that, in the space of a few months, those bogs which were formerly so soft as hardly to support the weight of a small dog, become so firm, that oxen and horses may tread upon them without any danger of sinking, at the very wettest season of the year. We have known a field of this nature that, by having only one such pit as has now been described opened in it, was entirely drained to the distance of above a hundred yards around it in every direction. But as it is possible that the stratum in which the water runs may be in some places interrupted, it will be in general expedient to make several of these pits, if the field is of great extent, always carrying the drain forward through the lowermost part of the field, or as

near the quag as you conveniently can, and sinking a pit wherever you may judge it will be most necessary. But if the stratum of gravel is not interrupted, there will be no violent burst of water at opening any of these after the first. To keep these wells from closing up after they are made, it is always expedient to fill them up with small stones immediately after they are made, which ought to rise to the height of the bottom of the drain.

If the whole field that is to be drained consists of one extensive bog, it will require a long time before the whole work can be entirely finished, as it will be impossible to open a drain through it till one part of it is first drained, and becomes solid ground. In a situation of this kind, the undertaker, after having opened a drain to convey the water from the lowest part of the bog, must approach as near to the swampy ground as he can, and there make his first pit, which will drain off the water from the nearest parts of the bog. When this has continued open for some time, and that part of the bog is become so solid as to admit of being worked, let him continue the ditch as far forward through it as the situation it is in will admit of, and there sink another pit, and proceed gradually forward in the same manner, making cross-cuts where necessary, till the whole is finished.

In this manner may any bog or track of sponting ground of this nature be rendered dry at a very inconsiderable expense; and as there can be no other method of draining ground of this sort effectually, we recommend the study of it to the attention of every diligent farmer who may have occasion for it. Let him first be extremely cautious in examining all the circumstances of his particular fields, that he may be certain which of the classes above enumerated it may be ranked with; and when he is perfectly sure of that, he may proceed without fear, being morally certain of success.

There is, however, one kind of damp ground not yet particularly specified. The soil we have now particularly in view consists of a deep strong clay that does not vary its nature even on the surface, but in as far as manures may have rendered it more friable and tender; the colour usually inclines to a reddish cast, and for the most part it is situated upon the side of some declivity. This bed of clay reaches to a great depth, without any variation, and is intermixed with a considerable quantity of small round stones. Many soils of the sort now described are apt to be continually moist and full of water during the winter season; but when the dry weather of summer sets in, the moisture is diminished, and the surface becomes hard, and it is rent into many large gaps which allow free admission to the sun and air, so as to scorch up almost every plant that is sown upon it: and as these soils are usually in themselves naturally fertile when drained, it is to be wished that some method could be discovered that would be less expensive than what is usually practised with regard to soils of this kind in Essex; where they make covered drains of two and a half feet deep, running diagonally through the whole field, at the distance of 20 feet from each other.

With regard to the making of these drains we have the following directions by T. B. Bayley, esq. of Hope, near Manchester: First make the main drains down the slope or fall of the field. When the land is very wet, or has not much fall, there should, in general, be two of these to a statute acre; for the shorter the narrow drains are, the less liable they will be to accidents. The width of the trench for the main drains should be 30 inches at top; but the width at the bottom must be regulated by the nature and size of the materials intended to be used. If the drain is to be made of bricks ten inches long, three inches thick, and four inches in breadth, then the bottom of the drain must be twelve inches; but if the common sale bricks are used, then the bottom must be proportionably contracted. In both cases there must be an interstice of one inch between the bottom brick and the sides of the trench, and the vacuity must be filled up with straw, rushes, or loose mould. For the purpose of making these drains, the bricks should be moulded ten inches long, four broad, and three thick, which dimensions always make the best drain.

The method to be pursued in constructing the main drains is as follows: When the ground is soft and spongy, the bottom of the drain is laid with bricks placed across. On these, on each side, two bricks are laid flat, one upon the other, forming a drain six inches high and four broad, which is covered with bricks laid flat. When the bottom of the trench is found to be a firm and solid body, as clay or marle, the bottom of the drain does not then require being laid with bricks. In that case the sides are formed by placing one brick edgeways instead of two laid flat.

This latter method is much cheaper, and in such land equally durable with the other. When stones are used instead of bricks, the bottom of the drain should be about eight inches in width. And here it will be proper to remark, that in all cases the bottom of the main drains must be sunk four inches below the level of the narrow ones, even at the point where the latter fall into them.

The main drains should be kept open till the narrow ones are begun from them, after which they may be finished; but before the earth is returned upon the stones or bricks, it will be advisable to throw in straw, rushes, or brushwood, to increase the freedom of the drain.

The small narrow drains should be cut at the distance of 16 or 18 feet from each other, and should fall into the main drain at very acute angles, to prevent any stoppage. At the point where they fall in, and eight or ten inches above it, they should be made firm with brick or stone. These drains should be 18 inches wide at top, and 16 at bottom. Fig. 61. represents a field with drains laid out according to Mr. Bayley's method. The black lines represent the main drains, and the dotted lines represent the narrow drains communicating with the former from all parts of the field.

The celebrated Mr. Elkington's method differs very little from that which we have now laid down, except that in draining lands of the first description pointed out in this article, viz. those which are rendered wet by waters confined under the surface, and attempting to rise in the manner of springs, he employs that very useful instrument, a draining auger, which he observes need not be above two inches in diameter. He was led to this discovery by attempting to drain a piece of ground of this kind on his farm at Princethorp, by making a trench of five feet deep, but without success: he thought it might be of use to know what kind of strata lay under

the trench. Accordingly he forced an iron crow, of about one inch and a half in diameter, three feet down; and upon taking it out, was agreeably surprised to find a great quantity of water burst forth, and run down the trench. This led him to think of applying an auger, an instrument fitter for the purpose of boring, which upon trial he found equalled his expectations; and by continuing the same plan with the auger at last drained all the wet parts of his farm, which were numerous, and had proved destructive to his sheep, by inducing the rot. When a morass is to be drained, his first object is to ascertain the direction in which the trench is to be dug. The principal of his rules for this, as laid before the Board of Agriculture, are these: 1. To obtain as much knowledge as possible respecting the strata in the neighbourhood. 2. To direct the trench so as to hit the bottom of the bed, which occasions the mischief, and the particular spot where the main spring lies. 3. If there are various beds through which the water issues, to prefer the stone one for draining the whole; and to make the trench from six to eight yards from the tail of the bed, where the rock ends, because in limestone and other rocks, the *tail*, as it is technically termed, is harder than any other part of the rock; but a few yards above it, it is softer, and the water is more accessible. The tail of these beds may often be found jutting out in a point. 4. To direct the trench in a line with the bottom of the hill; as it makes the best separation between the upland and meadow inclosures, where the spring can be best intercepted. The trench, however, must be carried in or near the line of the spring; for if it diverges to any distance, all chance of reaching the spring by tapping is over, and the labour of digging it probably lost. 5. To make a new trench rather than to tap the spring in any old brook or run of water. 6. and lastly, Having fixed on the line of direction, and marked out the trench, to begin at the bottom or lowest level, carrying the trench gradually up. The fall of the water need not be above a few inches in one hundred yards.

With respect to the main drain or trench, if it can be made a fence, Mr. Elkington prefers leaving it open; if not, he advises it to be covered. He then makes it either of brick or flat stones, and adds, that a trench made of a particular kind of bricks, invented by him, will last for 50 or 100 years.

DRAMA, a poem containing some certain action, and representing a true picture of human life, for the delight and improvement of mankind.

The principal species of the drama are two, comedy and tragedy. Some others there are of less note, as pastoral, satire, tragi-comedy, opera, &c. See Poetry.

DRANK, among farmers, a term used to denote wild oats, which never fail to infest worn-out lands; so that when plowed lands run to these weeds and thistles, the farmer knows it is high time to fallow them, or else to sow them with hay-seed, and make pasture of them. Some indeed destroy the drank, by sowing the lands with beans, and letting loose sheep upon them when young. This must be done in dry weather, and the sheep will eat up the drank and other weeds, without touching the beans.

DRAPERY, in sculpture and painting, signifies the representation of the clothing of human figures, and also hangings, tapestry, curtains, and most other things that are not figures or landscapes. See Drawing, and Painting.

DRASTIC, in physic, an epithet bestowed on such medicines as are of present efficacy, potent in their operation, and is commonly applied to cathartics.

DRAUGHT, or Draft. See Architecture.

Draught-hooks, are large hooks of iron, fixed on the cheeks of a cannon-carriage, two on each side, one near the trunnion-hole, and the other at the train, distinguished by the name of fore and hind draught-hooks. Large guns have draught-hooks near the middle transum, to which are fixed the chains that serve to keep the shafts of the limbers on a march. The fore and hind hooks are used for drawing a gun backwards or forwards, by men with strong ropes, called draught-ropes, fixed to these hooks.

DRAW, in the sea-language. A ship is said to draw so much water, according to the number of feet she sinks into it; so that if a ship sinks into the water 18 feet perpendicularly, she is said to draw 18 feet water; and according as she draws more or less, she is said to be of more or less draught.

Drawback, in commerce, certain duties, either of the customs or of the excise, allowed upon the exportation of some of our own manufactures; or upon certain foreign merchandize that has paid duty on importation. The oaths of the merchants importing and exporting are required to obtain the drawback of foreign goods, affirming the truth of the officer's certificate of the entry, and the due payment of the duties; and these may be made by the agent of any corporation or company, or by the known servant of any merchant usually employed in making his entries and paying his customs. In regard to foreign goods entered outwards, if less quantity or value is fraudulently shipped out than is expressed in the exporter's certificate, the goods mentioned in it, or their value, are forfeited, and no drawback allowed. Foreign goods exported by certificate, in order to obtain the drawback, if they are not shipped or exported, or if they are relanded, unless in case of distress, to save them from perishing, are to lose the benefit of the drawback, and are forfeited, all their value, with the vessels, horses, carriages, &c. employed in the relanding them; and the persons employed in the relanding, or by whose privity they are relanded, or into whose hands they shall knowingly come, are to forfeit double the amount of the drawback. Officers of the customs conniving at, or assisting in, any fraud relating to certificate goods, besides other penalties, are to forfeit their office, and to suffer six months imprisonment, without bail or mainprize; as are also masters, or persons belonging to the ships employed therein. Bonds given for the exportation of certificate goods from England to Ireland, must not be delivered up, nor drawback allowed for any goods, till a certificate under the hands and seals of the collector or comptroller, &c. of the customs is produced, testifying the landing.

Drawbridge, a bridge made after the manner of a floor, to draw up, or let down, as occasion serves, before the gate of a town or castle. See Bridge.

A drawbridge may be made after several different

modes, but the most common are made with plyers, twice the length of the gate, and a foot in diameter. The inner square is traversed with a cross, which serves for a counterpoise; and the chains which hang from the extremities of the plyers, to lift up or let down the bridge, are of iron or brass. In navigable rivers it is sometimes necessary to make the middle arch of bridges with two moveable platforms, to be raised occasionally, in order to let the masts and rigging of vessels pass through.

DRAWING, in painting, is the accurate representation and just symmetry of forms and proportions; whence a painter or sculptor is said to know much or little of drawing, according to his skill in these respects; and in like manner a figure of a man or other animal, a building, or any other object represented, is said to be in drawing or out of drawing. Drawing may justly be considered as the basis of painting; for it is but labour lost, when the painter endeavours to disguise by ingenious artifices of colour, the defects of forms which are fundamentally incorrect and incoherent.

Amongst the artists of antiquity, Apelles is recorded as the most eminent for the beauty of his drawing. Since the revival of the arts in Italy, Michael Angelo appears the most learned draughtsman, Raffaelle the most correct and graceful. The Roman and Florentine schools have excelled all others in this fundamental part of painting. Of the former, Raffaelle, Giulio Romano, Polydore, and their scholars; of the latter, M. Angelo, Leonardo da Vinci, and Andrea del Sarto, have been the most excellent. In the Bolognese school Annibal Caracci is particularly distinguished. In the French school Poussin, Le Sueur, and Le Brun; in our own, Mortimer and Barry have been the most celebrated.

DRAWING, a representation of objects on paper, by means of chalk, lead, charcoal, crayon, or common ink, or of Indian ink, or water-colours. When the latter method is used, it is called a washed or coloured drawing. This mode has of late years been improved in a singular degree, and it is at present practised with unprecedented excellence in England and other countries.

The drawing of great masters are frequently nothing more than such studies as they have made of various parts of their works, diligently designed after nature; as, in an historical subject, heads, hands, feet, or entire figures, draperies, animals, trees, and, in short, every object that can enter into the composition of the work.

DRAWING, *art of*. The art of delineating objects on the surface of any substance whatever. The fundamental part of this art is a knowledge of geometry and perspective: the study of both is therefore the first step towards the attainment of the art of drawing. See GEOMETRY and PERSPECTIVE.

The study of this art has at all times been held in high estimation by all polished nations, not only on account of the delightful amusement it is capable of affording, but from the superior consideration of its influence on the intellect and judgment, by forming the eye, and with it the mind, to habitual discriminations of dimension, regularity, proportion, and order. There is on record, a saying of Thomas earl of Arundel, lordmarshal of England, "that one who could not draw a little would never make an honest man."

The organ of sight is one of the quickest we possess, and takes in at a single glance an infinite variety of forms, but it cannot perfectly comprehend more than one object at a time, nor even that one accurately, without study and repeated observation. In order, therefore, to acquire a true notion of forms, the student must begin by studying successively each component part, and not pass to a second till he has well stored his memory by a sufficient practice of the first, otherwise he will lose his time, and infallibly protract his studies. Let him be careful also to acquire accuracy before he attempts quickness.

The surest mode therefore for the attainment of excellence in drawing, is to begin with such plain geometrical figures, as squares, arches, circles, ovals, cones, and cylinders, which will be useful in numerous forms of similar proportions, and having acquired sufficient facility and readiness in these figures, then to give to every object its due light and shade, according to its concavity or convexity, so as to convey the perfect idea of the elevation or depression, nearness or distance, of every part.

From this, the next step is the imitation of the forms of fruits, with their leaves; of flowers, herbs, trees of various kinds, &c. giving also to each its proper light and shade.

The third step is the representation, in the same manner, of beasts, birds, fishes, &c. &c.

From this the student may safely proceed to the imitation of the human figure, beginning, as before remarked, with its various parts, as the eye, mouth, hand, foot, &c. &c.; and thence the head, arm, leg, trunk; and lastly, the whole figure, carefully observing all its due proportions. When he is sufficiently master of the naked form, let him proceed to the study of drapery, learning how to clothe a figure, so as to give it every advantage of ornament, without interruption of its air and motion, grace or symmetry.

To these acquisitions are to be added a study of architecture, landscape, and all inanimate objects, or still life. See ARCHITECTURE, LANDSCAPE, and STILL LIFE.

The implements and materials most requisite for the young draughtsman are:

Drawing-boards for fixing the paper upon, so that it may not shift, and also for straining it, to prevent the colours, when laid wet upon the paper, from causing it to swell up, so as to be uneven. The simplest sort is made of a deal-board, framed square, with a strong piece across each end, to prevent warping. Upon this the paper may be fixed down with pins, wafers, or sealing-wax, or it may be strained with paste or glue as follows: having wetted the paper well with a sponge, lay it upon the board, and turning up the edges about half an inch, run a little good paste or glue all round under the under side, and press the paper down upon the board with a cloth, then set it by to dry; the paper, which had expanded and blistered up much when wet, will contract in drying, while the edges, being fixed immoveably, will strain quite flat and tight, and will be much better for drawing upon than when loose.

The best kind of drawing-boards, however, are made with a frame and a moveable pannel, upon which the paper is simply put wet, and then forced into the frame,

where it is confined by wedges at the back. This strains equally well, without the trouble of pasting, so that you may dry it at the fire; and it also looks much neater. These drawing-boards may be bought at most colour-shops. It is necessary to mention, that all the angles of drawing-boards should be exactly square.

Parallel rulers are for drawing parallel lines very readily; they are made of two pieces of ebony fastened together by brass bars, so as always to move parallel to each other. They may be bought of different kinds and prices, at the mathematical instrument makers'. See INSTRUMENT, MATHEMATICAL.

T-squares are rulers made in the form of the letter T, which are used with the drawing-boards; the short end, called the stock, being applied to the edge of the board, so as to slide forwards and backwards, while the long part, called the blade, is used for drawing lines by. These are more convenient than parallel rulers, when a drawing board is used, as by them you draw lines at right angles to each other at once, without using the compasses.

Dividing-compasses are instruments of brass and steel, for dividing lines, and laying down measures from scales, &c. They are generally sold in cases, containing also a steel pen, for drawing lines cleaner than can be done by a common pen, which is very useful where neatness is required; and points with a black-lead pencil, for putting into the compasses, when circles are to be described. These cases also contain scales of equal parts, such as are described under GEOMETRY, and protractors for laying down angles. All these may be had at the instrument-makers'.

Black-lead pencils are made of a mineral substance called plumbago, or black-lead, which is a carburet of iron, sawed into slips, and fitted into sticks of cedar. They are of various qualities: the best are fine without any grit, not too soft, and that cut easily without breaking. An inferior kind is made, by mixing up the dust of black-lead with gum or glue, and forming a composition, which is fitted into sticks in the same manner as the best: these are always gritty, and do not answer so well for most drawings, yet, being cheaper, they may be used upon many occasions. It is necessary to examine pencils before any quantity is bought, by cutting one of them, because the composition-pencils, having the same outward appearance, are often sold for the best.

Indian rubber, or elastic gum, as it is also called, is a substance very much like leather, which has the curious and useful property of erasing or defacing lines drawn with black-lead; it is therefore much used for this purpose. It is brought chiefly from South America, in the form of small bottles, which are cut up into slips. It is originally the juice of a tree that grows very abundantly in Surinam, and is like milk when exuded from the tree, but soon becomes solid when exposed to the air. The natives form balls of clay, which they smear over with this milk; when this coating is almost dry, they apply another, and so on, till it is of the required thickness; they then moisten the clay with water, which does not dissolve the Indian rubber, and wash it out. These bottles are used by the natives for containing water, or other liquors. It is a production common to the East Indies also, whence it is imported in various forms, more convenient for use than the bottles above-mentioned. See CAOUTCHOUC.

Indian ink. This very useful substance comes from China, where it is used for common writing, which is there performed with a brush instead of a pen. It is a solid substance, of a brownish-black colour; and the composition is not known, but is conjectured to be the gall of a species of cuttle-fish. When ground up with water upon a clean tile or earthenware plate, it may be either lighter or darker, as required, by adding to it more or less water. The best Indian ink is always stamped with Chinese characters, breaks with a glossy fracture, and feels smooth, and not gritty, when rubbed against the teeth. An inferior kind is made in England, but it may be easily known by its grittiness. This is made of lamp-black or ivory-black, ground up with gum.

Hair-pencils are made of camel's hair, put into a goose or swan's quill. To choose these, moisten them a little, and if they come to a point without splitting, they are good; if they do not, they are not fit for drawing with. The brushes used by the Chinese, made of a white hair fitted up in reeds, are very excellent for drawing, being much superior for landscapes, and many other purposes, to ours made of camel's hair, as they are more elastic. They are not sold here in common, but they may sometimes be met with.

Charcoal is used for slightly sketching the outlines of figures, in order to get the proportions, previous to making a drawing in chalk. The best charcoal for this purpose is that of the willow; it is cut into slips, and the strokes made with it may easily be rubbed out with a feather of goose's or duck's wing.

Black-chalk is a fossil substance, resembling slaty coal, which is cut into slips for drawing. It is generally used in an instrument called a port-crayon, which is made either of steel or brass. It is much employed for drawing figures, and is the best substance for this purpose, in making drawings from plaister, or after the life. It is more gritty than black lead, but is of a deeper black, and has not the glossiness of the former. It is of two kinds, French and Italian: the former is soft, the latter hard.

For mellowing and softening the shadows into each other, when black chalk is used, stumps are necessary. They are pieces of soft shamony leather, or blue paper, rolled up quite tight, and cut to a point.

White chalk is used, together with black, for laying on the lights. This is different from common chalk, being much harder. Tobacco-pipe clay will do very well instead of it.

Red chalk is a fossil substance of a red ochrey colour, which is sometimes used for drawing, but not so much now as it formerly was, the black being preferred; however, the red being cheaper, will do very well for some purposes.

Drawing paper. Any paper that will do for writing will do for drawing; but as the wire-marks in common writing paper are injurious, paper made without any wire-marks, called wove-paper, is generally used for this purpose. It is made of various sizes and thickness.

Middle-tint paper, is paper of a brownish or of a grey colour, which is used for drawing upon with black and white chalk. Being of a dark colour, the strokes of the white chalk are distinctly seen; and it saves a great deal of time in making drawings, as the tint of the paper answers for the half-shadow, so that all that is necessary to be done is to lay in the dark shadows and the light.

To proceed to directions for the practice of these rules, and the use of the materials which have been mentioned.

Mechanical Drawing.—In giving instructions for the study of drawing, attention must be paid to the particular branch of this art, to which the student wishes most to apply himself. If circumstances lead him to the study of architecture, machinery, or the delineation of objects perfectly regular; and if he wishes to draw plans, elevations, sections, &c. then geometry will form the entire foundation of all his future acquirements. The study of perspective necessarily follows, and with these two sciences he must be intimately acquainted. To these he must add a knowledge of the doctrines of the reflection of rays of light; since not only the outlines of regular objects may be drawn correctly and truly, by the rules of geometry and perspective, but even the forms and intensity of the various parts of the shadows of such objects may be found by certain and invariable rules, founded upon the principles of the reflection of the rays of light; and geometrical drawings should always be shadowed according to these rules. The materials and instruments necessary in this sort of drawing have been already described.

Pencils of black-lead are used for drawing the outlines, previous to their being drawn with ink, as it has the advantage of being easily rubbed out by the Indian rubber, when false lines are made. The Indian ink is rubbed down upon a plate or tile, and may be put into the drawing-pen belonging to the case of instruments, with a pen or hair-pencil. This ink is better to draw the lines with than common ink, the latter being liable to run, or spread, when the drawing is shadowed.

Having completed the outlines, Indian-ink is used for shadowing, as it may be diluted with water, so as to be of any required darkness, and may be softened off, where the objects require it, with water only and a hair-pencil. This branch of drawing we consider as a useful rather than as an ornamental art. It should be learned by every person, as answering the same purposes with writing, but in a much more perfect manner, in those cases to which it is applicable. This is particularly striking in descriptions of apparatus, and machinery of every kind. Every one must be sensible how imperfect are all written descriptions of those objects; whereas a drawing conveys, at a single glance, more satisfactory information than it is possible to convey by words. In the first rudiments of drawing, that is, in drawing geometrical figures and others of similar forms, genius and taste have therefore nothing to do: this degree of art is merely of a mechanical nature, which, like writing, may be acquired by every person possessed of moderate talents.

Drawing of flowers, fruits, herbs, trees, &c.—This first advance in art is so easy as to require little else than strict attention to imitate the objects placed before the eye, observing well those particulars which give the peculiar character of each, and mark the distinctness of the several species. In trees especially, care is to be taken that the oak, ash, elm, &c. &c. may each have its proper and distinct trunk, boughs, and foliage, in such a manner, that it shall be no more possible to mistake one kind of tree for another in the drawing than it is in nature. Nothing is more prejudicial to the student's progress than a habit of indiscriminate forms, which, though they denote a tree in general, do not decide its species.

In all these the process is the same as in the first rudiments, making first a correct outline, and afterwards giving the lights and shades, agreeably to the rules already learned.

Drawing of beasts, birds, fishes, &c.—In this step the student must not only study the forms of each class of the several animals, in the same manner as, in the preceding stage, he studied those of trees, but he must begin to observe the varieties of form, induced by the motions of the muscles, in all the actions of the head, body, or limbs, as well as the expression of face, characteristic action, and every other circumstance which distinguishes these from inanimate objects. In drawing beasts, he will begin to find a necessity of acquiring a general knowledge of anatomy.

The student who is unacquainted with the form and construction of the several bones which support and govern the animal frame, or does not know in what mode the muscles, moving those bones, are fixed to them, can make nothing of what appears of them through the integuments with which they are covered, which appearance, however, is the object of his pencil. It is impossible even for an artist to copy faithfully what he sees, unless he thoroughly understands it; let him employ ever so much time and study in the attempt, it cannot but be attended with many and great mistakes; just as it must happen to a man who undertakes to copy something in a language which he does not understand, or to translate into his own what has been written in another on a subject with which he is not acquainted. This subject will be more fully treated under the ensuing head, where, as well as in the subsequent articles, will also be found more particular instructions for the use of the proper materials for drawing.

Drawing the human figure.—The study of the human figure has always been considered by artists as the most important part of the art. It is the most difficult, and is by many considered as contributing the most of any to general improvement; though there are some who carry this idea to too great an extent, saying, that a person who can draw the human figure well, can draw every thing besides. But this, it is well known, is not the case, there being many artists who can draw the figure very well, who cannot draw landscape nor architecture. To draw any thing well, requires a particular study. The study of the figure, however, includes all the finest principles of the art; and when the eye of the student has been accustomed to copy faithfully all the minute circumstances which constitute the character of a figure, and to attend to the innumerable beauties and graceful forms which it presents, he will be better qua-

lified to pursue with advantage every other branch of the fine arts.

In learning to draw the human figure, it is necessary to begin with each of the parts separately, and after sufficient practice in that way, to proceed to put them together in the complete figure. For instance, the head being the most important part of the human body, it should be studied first. For this purpose, the student should copy the best drawings he can procure of the eye, mouth, nose, and ear, separately, and on a large scale; and of these a front view, profile or side view, oblique view, &c.

The readiest materials for drawing these, as well as all other parts of the figure, are black chalk, or black lead; the former may be used either upon white paper, or upon middle-tint paper; and in that case, white chalk may be used for laying on the lights. Black lead is only used upon white paper. A piece of soft charcoal may be made use of, for first slightly sketching in the general form, which must afterwards be gone over and corrected with the black chalk. The false lines of the black lead may be removed by the Indian rubber; but the student must remember to be as sparing as possible of this, as it is more improving to endeavour to draw every thing correct and decided at once, and not to trust to the being able to erase the lines which are wrong.

The shadows may be laid on by drawing parallel curve-lines, according to the situation of the part, crossing them occasionally, and softening them in with more delicate lines, where necessary.

All the parts of a human figure are composed of curved surfaces; no straight lines are ever admissible, but every line should have a graceful turn; and it is this circumstance particularly, that occasions the study of the figure to give so much freedom in drawing. Care should be taken that no lines ever cross each other at right angles, which gives a disagreeable net-like appearance; neither should the crossings be too oblique, as then they are confused; a proper medium will be acquired by the study of good drawings or prints; in general, however, crossing should be avoided as much as possible. Sometimes the shadows are rubbed in, or their edges are softened, with a stump, which is a very expeditious way, and produces a fine effect; but it should be used with discretion, as it is better to execute the shadows in a clear and regular manner by soft lines. Care should be taken not to make the lines harsh and hard, like those of an engraving; they should be softer and more mellow. On this account, drawings are much better to learn from than prints, as, by copying the latter, the student is very apt to acquire a dry and hard manner. But we particularly caution him to avoid copying with a pen all the lines in engravings used for the shadows, which some, who have not been accustomed to see good drawings, are apt to do.

Many productions of this kind have been executed with an immensity of labour, and have been thought very fine by those who had but little knowledge of the art; yet artists, and those who are good judges, always consider them as very disgusting, and lament to see so much patience and labour misapplied.

In copper-plate engravings, there are no other means of producing shadows than by lines, at least with an equal effect; but this arises from the nature of the process; and in drawing, which is of a very different nature, there is not the same necessity for them. In general it should be observed, that the less labour there appears in any drawing, the better it is; and that though every possible pains should be taken to make drawings or paintings excellent, yet this labour should be always disguised as much as possible, and the whole should appear as if executed with the greatest ease.

In learning to draw, it is of more importance than is generally supposed, to copy from the finest works only. The most prejudicial quality of a model is mediocrity. The bad strike and disgust, but those that are not good, nor absolutely bad, deceive us by offering a dangerous facility. It is for this reason that engraving contributes to the progress of the arts, when it is employed on subjects that are judiciously chosen; but is too often prejudicial by the indifferent works it multiplies without number. But let Raffaelle be copied by skilful engravers, let a young artist profit by his labours, and works without dignity and expression will soon become intolerable to him; he will perceive to what an elevation the excellence of the art can raise him.

The way to avoid mediocrity is by the study and imitation of beautiful productions, or, in want of them, of the most finished translations that have been made from them: for so we may call beautiful prints. Let a young draftsman study the heads of Raffaelle, and he will not see without disgust the sordid figures of indifferent painters. But if you feed him with insipid substances, he will soon lose the taste necessary to relish great excellences. In the one case he will advance firmly in his career; in the other he will continually totter, and even not be sensible of his own weakness.

Having copied frequently the parts of a face, he is next to proceed to the entire head, drawing first a front view, then a profile, a three-quarter, and so on, varying it in every possible direction, till he is thoroughly acquainted with the appearance of all the principal lines in every situation.

The student should now accompany his lessons by making observations on good casts and living models; but more particularly the former, as individual nature is seldom fine, and there is danger of copying what is bad, and acquiring false ideas of beauty. By these exercises he will have acquired some facility in handling his pencil, and he will be thus prepared for the study of the whole figure. But before he can proceed to this with advantage, we would recommend to him the study of anatomy, for the same reasons which have been given under the preceding head. But it is to be remarked, that it is not necessary for the designer to study anatomy as a surgeon, nor to make himself acquainted with all the nerves, veins, &c. It is sufficient to study the skeleton, and the muscles which cover them, and of these he should most particularly make himself familiar with those muscles which most frequently appear and come into action. For this purpose he should procure plaister casts of the anatomy of the human body, and consult treatises written upon the subject; and if he has opportunity, it will be proper afterwards to attend discussions and lectures on anatomy. He should also use every possible opportunity of making observations on

the actions of the muscles in nature. Being thus thoroughly prepared, he will be enabled to draw the human figure with great advantage, and he will make a more rapid progress than he could have done without these previous studies. Until the student, however, has imbibed a proper relish for beautiful proportions, and been well-grounded in their principles, he should not proceed to draw from living models.

In drawing from plaister casts, a good deal depends upon choosing a proper view, and placing the model properly with regard to the light, which should always come in obliquely from above, as it generally does in the day-time. If a candle is used, it should be so high as to cast the light downwards upon the model. The light should only come from one part, as cross-lights will distract and spoil the shadows.

Attitude and action of the Muscles.—The general knowledge of the bones and muscles having been acquired by the study of anatomy, it remains that the draughtsman be careful not to represent any appearance of them contradictory to the attitude of the figure, and the exertion required by it. This demands, in fact, nothing more than a strict attention to nature, who never directs a muscle to act, unless it is necessary to the purpose designed. In this attention the Greek statuaries have particularly excelled. Regard is also to be had to the difference of character in the person represented, as whether a man be strong or weak, and likewise to sex, age, &c.

The muscles in general do not appear in the female so strongly as in the male. No action of a woman although she exert her utmost strength, will occasion such swellings of the muscles as appear in men; the greater quantity of fat, which lies under the skin of women, clothing the muscles so generally, as to prevent every such appearance.

In order to represent properly and consistently the attitude or action of the figure, it is of the highest importance to attend to the parts or limbs employed in performing the action and producing the attitude. For instance, if the figure is standing, the foot must be placed in a right line, or perpendicular to the trunk or bulk of the body, where the centre of gravity may be supposed to fall. This centre is determined by the heel: or, if the figure is upon tiptoe, then the ball of the great toe is in the centre. The muscles of the leg which supports the body ought to be swelled, and their tendons drawn more to an extension than those of the other leg, which is only placed so as to receive the weight of the body towards that way to which the action inclines it. For example, suppose a man striking with a club at any thing before him towards the left side; then let his right leg be placed so as to receive the whole weight of the body, and the left loosely touching the ground with its toes. Here the external muscles of the right leg ought to be expressed very strongly, but those of the left scarcely more than if it was in some sedentary posture, except that, in the present case, the foot being extended, the muscles which compose the calf of the leg are in action, and appear very strong. It is not meant that all the muscles of the right leg, which supports the weight of the body, ought to be expressed very strong or equally swelled, but those principally which are most concerned in the action or posture that the leg is then in. For example, if the leg or tibia is extended, then the extending muscles placed on the thigh are most swelled; if it is bent, then the bending muscles and their tendons appear most. The like may be observed of the whole body in general when it is put into vigorous action. The Greek statue of Laocoon furnishes an example of this muscular appearance through the whole; but in the Antinous Apollo, and other figures disposed in postures where no considerable actions are designed, the muscles are expressed more faintly.

It is of great importance to an artist to be acquainted with the most obvious effects of the action of those muscles which are placed externally on the human body, for these vary with every alteration of posture, and are variously enlarged and changed in their appearance by every effort that is dictated by the will.

The following are frequently given as a few instances of the natural actions of the muscles, and will serve to direct the student to a fuller investigation of the subject.

Effects of the exertions of the nucles.—If either of the mastoid muscles act, the head is turned to the contrary side, and the muscle which performs that action appears very plain under the skin. If the arms are lifted up, the deltoid muscles placed on the shoulders, which perform that action, swell, and make the extremities of the spines of the shoulder-blades, called the tops of the shoulders, appear indented or hollow. The shoulder-blades following the elevation of the arms, their bases incline at that time obliquely downward. If the arms are drawn down, put forwards, or pulled backwards, the shoulder-blades necessarily vary their positions accordingly. All these particulars are to be learned by consulting the life only: when being well acquainted with what then appears in every action, the student will be able to form an adequate idea how it ought to be expressed.

When the cubit or fore-arm is bent, the biceps has its belly very much raised. The same happens in the triceps, when the arm is extended. The straight muscles of the abdomen appear very strong when rising from a decumbent posture. Those parts of the great serratus muscle which are received into the teeth or beginnings of the obliquos descendens muscle immediately below, are very much swelled when the shoulder on the same side is brought forwards; that serratus muscle then being employed in drawing the scapula forwards.

The long extending muscles of the trunk act alternately in walking, after this manner: if the right leg bears the weight of the body, and the left is in translation as on tiptoe, the last-mentioned muscles of the back on the left side may be observed to be tumefied on the other side about the region of the loins, and so on the other side. The trochanters, or outward and uppermost heads of the thigh-bones, vary so greatly in their positions, that no precise observations can explain their several appearances; but the study after the life ought to be chiefly relied on. If the thigh is extended, as when the whole weight of the body rests on that side, the glutæus or buttock-muscle alters its appearance; and if the thigh be drawn backwards, that muscle appears still more and more tumefied. When the whole leg is drawn

upwards and forwards, and at the same time the foot is inclined inwards, the upper part of the sartorius muscle appears to rise very strongly; in other positions of the thigh, that muscle makes a furrowing appearence in its whole progress. If a man is upon tiptoe, the extending muscles of the leg placed on the fore-part of the thigh, and those of the foot that compose the calf of the leg, appear very strong, and the long peronæus makes a considerable indentation or furrowing at that time, in its progress on the outside of the leg. See MUSCLES.

Symmetry, or proportion, will be best learned by copying after the antique statues, of which plaister casts may be easily procured. Nature, which in the formation of every species, seems to have aimed at the last degree of perfection, does not appear to have been equally solicitous in the production of individuals. Parts of individuals are frequently as beautiful as possible, but a complete whole is never to be met with.

The practice of the ancient Greek statuaries was, to select from various individuals the most beautiful parts, and by combining them, to produce figures more perfectly beautiful than nature ever presented. See PROPORTION, STATUES ANTIQUE.

Measures of the several parts of the human figure.—The moderns ordinarily divide the human figure into ten faces; that is, from the crown of the head to the sole of the foot, in the manner following. From the crown of the head to the forehead, is the third part of the face. The face begins at the lowest hairs which are upon the forehead, and ends at the bottom of the chin. The face is divided into three proportional parts: the first contains the forehead, the second the nose, and the third the mouth and chin. From the chin to the pit between the collar-bones are two lengths of a nose. From the pit betwixt the collar-bones to the bottom of the breast one face. From the bottom of the breast to the naval one face. From the naval to the genitals one face. From the genitals to the upper part of the knee two faces. The knee contains half a face. From the lower part of the knee to the ancle two faces. From the ancle to the sole of the foot half a face.

A man, when his arms are stretched out, is from the longest finger of his right hand to the longest of his left, as broad as he is long. From one side of his breast to the other, two faces. The bone of the arm, called humerus, is the length of two faces, from the shoulder to the elbow. From the end of the elbow to the root of the little finger, the bone called cubitus, with part of the hand, contain two faces. From the box of the shoulder-blade to the pit betwixt the collar-bones, one face. If you will be satisfied in the measures of breadth, from the extremity of one finger to the other, so that this breadth should be equal to the length of the body, you must observe that the boxes of the elbows with the humerus, and of the humerus with the shoulder-blade, bear the proportions of half a face, when the arms are stretched out. The sole of the foot is the sixth part of the figure. The thumb contains a nose. The inside of the arm, from the place where the muscle disappears, which makes the breast, called the pectoral muscle, to the middle of the arm, four noses. From the middle of the arm to the beginning of the hand, five noses. The longest toe is a nose long. The two utmost parts of the teats, and the pit betwixt the collar-bones of a woman' make an equilateral triangle.

For the breadth of the limbs no precise measures can be given; because the measures themselves are changeable, according to the quality of the persons, and according to the movement of the muscles. In general, however, the hands are twice as long as they are broad, and each of their parts has its length, breadth, and thickness. The nail upon the finger is about half the joint it is upon. The length of the foot is a sixth part of the height of a person; and the length is five-eighths more than the breadth. The length of the face and hands ought to be exactly equal, and makes but just the tenth part of a person's height.

The rules in drawing children are as follow: Some make a child to contain five measures of the head, viz. from the top of the head to the privities three, and in the thighs and legs two more; the breadth between the two shoulders the length of a head and a half; the breadth of the body above the naval the length of one head; and the breadth of the upper part of the thigh is the third part of two lengths of the head; the breadth of the knee is just the measure there is betwixt the eyes and the chin; the small of the leg, and the brawn of the arm, are of the thickness of the neck.

As to the order and manner of proceeding in drawing the human figure, it is first requisite to mark the exact extent which you propose to give to the whole figure, both in height and breadth; next divide, agreeably to the most general proportions; and having thus ascertained the place where each part is to be drawn, sketch the head, then the shoulders, in their exact breadth; then draw the trunk of the body, beginning with the arm-pits (leaving the arms till afterwards) and so down to the hips on both sides, being sure to observe the exact breadth of the waist. When you have done this, then draw that leg which the body stands upon, and afterwards the other, which stands loose, then draw the arms, and last of all the hands.

Endeavour to form all the parts of your figure with truth, and in just proportion, not one arm or one leg bigger or less than the other; not broad shoulders with a thin slender waist, not raw and bony arms with thick and gouty legs; but let there be a kind of harmony and agreement amongst the members, and an agreeable symmetry throughout the whole figure.

But as the essence of drawing consists in making at first a good sketch, you must in this particular be very careful and accurate; draw no part perfect or exact, till you see whether the whole draught be good; and when you have altered that to your mind, you may then finish one part after another as curiously as you can. In drawing the eyes, ears, legs, arms, hands, feet, &c. great care, study, and practice are requisite; this must be learned, as before remarked, by carefully imitating the best drawings you can get of eyes, ears, &c. for as to the mechanical rules of drawing them by lines and measures, they are not only perplexed and difficult, but also contrary to the practice of the best masters. The actions and postures of the hand are so many and various, that no certain rules can be given for drawing them that will universally hold good; and as the hands and feet are difficult members to draw, it is necessary, and

well worth while, to bestow due time and pains about them, carefully imitating their various postures and actions, so as not only to avoid all lameness and imperfection, but also to give them life and spirit.

In drawing a labouring man, you must represent him with strong limbs and raised muscles, swelling and standing out, especially in bearing burdens, drawing weights, leaping, walking, combating, or such-like violent exercises. In representing persons asleep, you must carefully avoid giving any such postures or actions in their lying as would not in all probability afford rest; for a great want of judgment would appear in representing their limbs or bodies supported by their own force, and not by the help of something else.

Let it be remembered, as a general observation, always to begin with the right side of the draught you are making, that is, on your own left side, as is customary in writing, for by so doing, you will always have the part that is done before your eyes, and the rest will follow with ease; whereas, if you begin with the left side, your hand and arm will cover what you do first, and deprive you of the sight of it.

Expression of the passions.—With regard to the representations of the passions, Mr. de Piles observes, that it is absurd, as well as impossible, to pretend giving such particular demonstration of them as to fix their expression to certain strokes which the painter should be obliged to make use of, as essential and invariable rules. See EXPRESSION.

Drawing of drapery.—In the art of clothing the figures, or casting the drapery properly and elegantly upon them, many things are to be observed. 1. The eye must never be in doubt of its object; but the shape and proportion of the part or limb, which the drapery is supposed to cover, must appear, at least so far as art and probability will permit. 2. The drapery must not sit too close to the parts of the body, but let it seem to flow round, as it were to embrace them, yet so as that the figure may be easy, and have a free motion. 3. The draperies which cover those parts that are exposed to great light, must not be so deeply shaded as to seem to pierce them; nor should those members be crossed by folds that are too strong, lest by the too great darkness of their shades the limbs look as if they were broken. 4. The great folds must be drawn first, and then stroked into lesser ones; and great care must be taken that they do not cross one another improperly. 5. Folds in general should be large, and as few as possible: however, they must be greater or less according to the quantity and quality of the stuffs of which the drapery is supposed to be made. The quality of the persons is also to be considered in the drapery. If they are magistrates, their draperies ought to be large and ample; if country clowns or slaves, they ought to be coarse and short; if ladies or nymphs, light and soft. 6. Suit the garments to the body, and make them bend with it, according as it stands in or out, straight or crooked, or as it bends one way or another; and the closer the garments fit to the body, the narrower and smaller must be the folds. 7. Folds well imagined give much spirit to any kind of action; because their motion implies a motion in the acting member, which seems to draw them forcibly, and makes them more or less stirring as the action is more or less violent. 8. An artful complication of folds in a circular manner greatly helps the foreshortenings. 9. All folds consist of two shades and no more; which you may turn with the garment at pleasure, shadowing the inner side deeper, and the outer more faintly. 10. The shades in silk and fine linen are very thick and small, requiring little folds, and a light shadow. 11. Observe the motion of the air or wind, in order to draw the loose apparel all flying one way; and draw that part of the garment that adheres closets to the body before you draw the looser part that flies off from it, lest, by drawing the loose part of the garment first, you should mistake the position of the figure, and place it improperly. 12. Rich ornaments, when judiciously and sparingly used, many sometimes contribute to the beauty of draperies; but such ornaments are far below the dignity of angels or heavenly figures; the grandeur of whose draperies ought rather to consist in the boldness and nobleness of the folds, than in the quality of the stuff, or the glitter of ornaments. 13. Light and flying draperies are proper only to figures in strong motion, or in the wind: but when in a calm place, and free from violent action, their draperies should be large and flowing; that, by their contrast and the fall of the folds, they may appear with grace and dignity.

Drawing of landscapes.—Every one who wishes to learn to draw landscapes will particularly find the advantages arising from the previous study of perspective. This will enable him not only to understand and draw all the parts of buildings which so frequently form a principal feature in views of places, but will also give him true ideas of the method of expressing distances, the winding of roads, and a variety of particulars that are continually occurring.

Having made himself master of the principal difficulties in perspective, he should next copy some good drawings; and here it is of great importance that what he copies first should be very excellent; for it is an absurd notion, though entertained by many, that indifferent drawings will do to begin with, or to bring the hand in, as it is termed; but, as a great master justly observes, the most likely effect these can produce, will be to put the hand out.

In choosing drawings to copy for beginners, particular attention should be paid to select those where the outlines or forms of the objects are distinctly and correctly drawn, and not those in which a good effect only has been principally aimed at. The first thing to be studied is, to be able to express with the black-lead pencil, decidedly and truly, the forms of all sorts of objects; and till this is attained, no attempt should be made at finished drawings or pictures.

By neglecting this important circumstance, many who would have excelled, if they had been put into the right way, have completely lost themselves, and run quite-wild, by aiming at producing merely dashing effects, which, though very captivating at first, do not continue to maintain that power over the mind, as when they are accompanied by true drawing, and beautiful and correct forms.

Black lead is the most useful material for drawing the outlines of landscapes, which are best executed with this alone, and should not be gone over afterwards by the

pen, which, except it be very judiciously managed, generally gives an appearance of hardness.

Indian ink alone should be used for the shadows till the student has advanced very considerably; nor till then should colours of any kind be used. Beginners are always desirous of producing pictures and making coloured drawings; but nothing is more hurtful than the practising this too early. The first thing to be learned is, to draw forms correctly; next, the mode of shadowing objects truly; then the general light and shadow of a drawing, and, with this, good composition. All this is best learned by using black lead, black chalk, white chalk, Indian ink, and these separately or combined, according to the taste of the student; but he should never think of colours till he has made very considerable progress.

When colours are employed, they should be used with great caution and judgment. Nothing is so disgusting as to see coloured drawings where the reds, greens, and blues, are laid on in the most violent manner, without any regard to harmony. Those who execute such vile daubings, will say in their defence, that nothing can be greener than grass, nor bluer than the sky; but they should consider, that nature employs such a multitude of little shadows, and such a variety of different tints intermixed with her colours, that the harshness of the original colour is corrected, and the effect of the whole is very different from a raw and distinct colour laid upon white paper. A single distinct colour is always bad in a landscape; and the tints should always be varied and broken in every part. Though we should have recourse to the study of nature, in preference to any master, for the study of colouring, yet it requires some judgment to know what part of nature is to be studied, and what is to be avoided; for in nature herself, there are many parts which are bad, and to copy them would do more harm than good. The student in colouring must examine, with every possible attention, the colouring of old walls, broken and stained by time and the weather, old thatch, old tiles, rotten wood; in short, all objects which are covered with moss, stains, and tints of various kinds; there he will find all that is most perfect and harmonious in colouring. Let him copy these with every possible care, and avoid as bad all objects which are of a uniform decided colour. This has been the practice of all the great masters who have excelled in this captivating part of the art. In short, after learning the first principles of drawing, he cannot too soon have recourse to nature; he will obtain from her the materials for acquiring every species of excellence, in a greater degree than from the works of the first masters. The study of these, however, will greatly abridge his labour, and it should go hand in hand with drawing from nature.

In landscapes, the scenes most generally to be met with, and which are most generally interesting, are of the picturesque kind, such as cottages and rustic scenery. In these, straight lines should be avoided, and every thing that is old and broken is preferable to what is new, as affording more variety. Old thatch, old tiles, old plaister, old fencing, are more picturesque, and fitter for the pencil, than the same species of objects when new and entire. An old house almost tumbling down, whose parts are broken and ruinous, some bulging out, and the whole stained and tinted with a variety of chaste and harmonious colours by the pencil of nature, is infinitely preferable, as a subject for a picture, to any new house or gentleman's seat, though the latter may be a more comfortable habitation to live in.

In the same way, an old worn-out carthorse is a much fitter animal to draw from, and a finer subject for the pencil, than a sleek and clean poney; and an ass with a rough coat is more picturesque than the same animal kept in nice order.

In subjects of the grand kind on the contrary, such as magnificent buildings, cities, streets, &c. straight lines are often necessary and proper, as these objects are rather of the sublime than the picturesque kind; and straight lines, and a degree of regularity, form part of the sublime. The employment of straight lines, however, requires great skill and knowledge of the art, to prevent them from appearing bad, and they can only be employed with success by those who have attained to considerable eminence.

The fewer colours that are used in a drawing the better, as harmony is most easily preserved, and by the mixture of a few, every possible tint may be obtained.

The sun's rays were considered by sir Isaac Newton to be composed of seven primitive colours; but later observations have made them to consist only of three; red, blue, and yellow; so that all the vast variety of tints which we see in nature, is formed by the mixture of these in various proportion. If we had pigments of these colours perfectly pure, we should have no occasion for more than these three; but this is not the case, and therefore we are obliged to have recourse to materials of other broken tints. The colours that are found to be the most useful in drawing landscapes in water-colours are, lake, indigo, Prussian blue, gamboge, light red, yellow-ochre, burnt terra Sienna, burnt umber, and Cologne earth. Some of the other colours may be occasionally useful, but these are all that are necessary for general use.

The best sort of water-colours are those mixed with gum and made up into cakes, as these may be used by rubbing upon a tile, in the same manner as Indian ink.

For a more particular account of the colours used in washing of drawings, and best methods of preparing them, see WASHING, and WATER-COLOURS.

GENERAL RULES.

Correctness of outline.—This is the first point to be attained, and can only be the result of patient diligence and long practice. To gain the free use of the pencil or port-crayon, let the student accustom himself to hold it farther from the point than a pen is held in writing, by which means he will have the full command and direction of it. In drawing of figures in Indian ink, the use of the pencil is to draw the first sketches or outlines; as any stroke or line that is amiss, may in this be more easily rubbed out than in any other thing; and when you have made your sketch as correct as you can with the pencil, you may then draw carefully the best outline you have got, with your crow-quill pen and ink. The ink made use of for this purpose, must not be the common, but Indian ink; being much softer than the other, and not running; and by mixing it with water, it may be made to any degree of strength, and may be used in a pen like

common ink. After using the ink, you may wipe out the pencil-lines by rubbing the piece gently with the crumb of stale bread. Having thus got your outline discharged, your next work is to shade the figures, as directed; either by drawing fine strokes with your pen, where it requires to be shaded, or by washing it with the hair-pencil and the Indian ink. As to the rule and compasses, they are never or rarely to be used, except in measuring the proportion of your figures, after you have drawn them, to prove whether they are right or not; or in houses, fortifications, and other pieces of architecture.

Red lead and red or black chalk are used in the same manner as black lead. White chalk and tobacco-pipe clay are used in heightening or giving strong lights, and in drawing on coloured paper. Pastils or crayons are any colours, mixed with tobacco-pipe clay, which, while soft and in the consistency of a paste, is rolled up in pieces, about the thickness of a quill, and two or three inches in length, and then dried: they are generally used on coloured paper: and the colours are rubbed and wrought one into another in such a manner that no strokes appear, but the whole looks as if it was done with a brush.

Of the general distribution of lights and shades.—As soon as the learner has made himself acquainted with the drawing of forms, his next endeavour must be to learn the art of disposing the light and shade of every object properly. The best rule for doing this is, to consider from what point, and in what direction, the light falls upon the objects which he is delineating, and to let all his lights and shades be placed according to that direction throughout the whole work. It is the artful management of light and shade that gives the appearance of substance, roundness, and distance, to whatever bodies are represented by drawing. Draw a circle on a piece of paper; fill it up with any even colour, and it will appear to be a body with a round circumference and flat sides: but by colouring it stronger in the middle, and causing it gradually to weaken towards the circumference, it will receive a convex appearance like that of a ball or globe: wherever the vivacity of colour is strongest, that part of the object catches the sight first, and appears nearest to it: whereas its weakness and goings off are more and more broken and faint, and seem to fly farther off from the sight. In rounding the parts of any object, the extremities in turning must lose themselves insensibly and confusedly, without precipitating the light all of a sudden into the shadows, or shadows into the light, but the passage of the one into the other must be common and imperceptible; that is, by degrees of light into shadow, and shadow into light. Objects that are painted light, must have a sufficient breadth of shadow to sustain them; and dark bodies must have a sudden light behind, to detach them from the ground, or from those objects that are placed behind them; otherwise they will appear confusedly as sticking upon each other; whereas the opposition of shade to a light object, and of light to a dark one, gives a projection, and separates them from other bodies.

There should be a balance preserved between the lights and shadows: a broad light ought not to be introduced into a draught without a large shadow. The nearer any object is to the eye, it is seen so much the stronger and plainer: the sight is weakened by distances, and the more remote any object is, it is seen in a more imperfect manner. Therefore, those objects which are placed foremost to the view, ought to be more finished than those that are cast behind; and they should have such a relative dominion over each other, that as one object by its heightenings causes others to retire more backwards, so the same object must be chased, and made to appear farther from the sight than others which are more strongly illuminated.

It is not sufficient that remote objects be only coloured in a more faint and languid manner; but, according to their distance, the parts must appear more or less confused: the eye not being able to discover minutely what is far separated from it. Pure and unmixed white either draws an object nearer, or carries it off to a greater distance. If it be accompanied with black, the opposition of light and dark renders the object more sensible, and brings it nearer to the advanced part, but pure white, being the lightest of colours, unless it be forced forwards, and supported by black, will fly off to the remotest view. As for pure black, it is the heaviest, most earthy, and most sensible of all colours, and brings the objects nearer to the sight; it must be placed in masses, be insensibly confused, and have its proper reposes.

In the representation of bodies give them always such lights as are most proper and convenient to their supposed situations. If the objects are in the fields or open air, and the sun not visible, or obscured by clouds, you must then introduce almost an universal light, though not warm and strong, and your shades must be faint; but when the sun is conspicuous, and shines in its full lustre, then the light must be very strong and bold, and the shadows very dark. If the objects you represent be supposed in a room, a little, but not very much illuminated, and you survey it from without, and stand on a level with the light that strikes upon it, the shadows of that figure must be very soft, whereby the figure itself will appear beauteous to the eye; and will, notwithstanding the softness of the shadow, seem as embossed, and come boldly out. A small light illuminating the body occasions the shadows on the dark side to be large, and their extremities to be very bold. On the other hand, a broad light makes the shadows on the darker side to be more distinct and more soft in their limitations.

Reflection is to be used in delineating glittering or shining bodies, as glass, pearls, silver, &c. Let the cause of the reflection, be it more or less, be seen in the thing itself. Place all your lights one way through the whole work; and if the light falls sideways on the picture, the other side, which is the farthest from the light, must be made the darkest. That part of the body must be made lightest which has the light most opposite to it; if the light be placed above the head, then the top of the head must be made lightest; the shoulder must receive the next greater degree of light; and thus must you continue to shade, losing the light by degrees. By how much one part of the body projects more than another, it may by so much be made the lighter: and, on the contrary, those parts that bend inward must be made so much the darker. Two equal lights must never be made in one and the same picture; the greater is to strike forcibly into the middle, and with greatest lustre on those

parts of the design where the principal figures and strength of the action seem to lie, diminishing it gradually as it approaches nearest the extremities of the piece.

In copying, before you begin your work, view the original with close attention; divide it in your mind into several parts; observe the length, the breadth, and the similitude of each part; consider their proportion to each other and the whole, the distances from one part to the other, and what parts lie opposite to each other.

After you have done your copy, view it afresh, by comparing it with the original, for the discovering and amending of faults, as it will not only serve to perfect you in that particular draught, but will improve your knowledge of lines and proportions in general, and in time enable you for the nearest imitations. Draw the outlines in a gliding manner, large and smooth, which will give them the resemblance of life and motion. Preserve in your draught a strong resemblance between the parts and the whole; every member ought to be made to agree, and the eyes, legs, hands, and feet, should be exactly paired.

Having good copies to draw after, learn to reduce them to other proportions, either larger or smaller, and this by frequent practice.

PARTICULAR DIRECTIONS.

In drawing after a picture or print, take care to place it in such a light that the gloss of the colours may not interrupt your view, but so that the light and your eye may fall equally and obliquely upon the piece. Let the piece be placed at such a distance, that upon opening your eyes, you may view it all at once: and the larger the picture is, it should be so much placed off at the greater distance; but right before you, and a little reclined.

Draw all your outlines at first very faint with a coal, which may easily be rubbed out again with the feather of a duck's wing, or the crumb of bread; and these outlines should be true, and agreeable to the pattern. The outlines next the light, should be drawn more faint; and when you have drawn one feature it should be a direction for you, in some measure, to draw another, by observing with your eye the distance from that to the next feature, making a full mark at the place with your coal, then draw it, and so on to the next, till you have drawn the whole.

Then observe the middle of the picture you would copy, and touch upon the paper with the point of your coal; afterwards observe the more conspicuous and uppermost figures, if there are more than one, which you are to touch lightly in their proper places. Thus running over the whole draught, you will see, as it were, the skeleton of the piece you are to draw.

Having made out these sketches, view them diligently, to see if they answer your pattern or not; for the gestures of the life ought to show themselves eminently in the first and rudest draught of the piece; correct and amend whatever you perceive amiss; adding and diminishing as it varies from the pattern, by which means it will be brought nearer and nearer to the life.

Observe the distance of one limb, joint, or muscle, from another, and the same in all other accidents of the figure; their length, breadth, turnings, &c. Shadow next to the light very faintly: and where you see bold and free touches, be not timorous in expressing the same. In drawing a head after the life, or otherwise, take care to place the features exactly right upon the cross-lines, whether it be a full face or three-quarter face. In fore-shortening, you must make the cross-lines to fly upwards, but where the aspect is downwards, they must be made downwards in a circular manner.

In copying the exact appearance of prints, having drawn the outlines true with a coal, you are to proceed to trace the same lines again with a pen, Indian ink, &c. drawing them with more exactness; and by imitating all the hatches, with their exact distances one from another, their crossings, turnings, and windings, with more boldness and freedom, perfect your design.

In drawing after a naked body, bear constantly in mind what has been remarked above, that all the muscles are not to be so plainly expressed as in anatomical figures; but that side whose parts are most apparent, and of signification in the performance of any action, must be made to appear more or less, according to the force of that action.

In drawing young persons, the muscles must not appear manifestly so hard as in elder and full-grown persons; the same thing is to be observed as to fat and fleshy persons, and such as are very delicate and beautiful; and in women scarce any muscles at all are to be expressed, or but very little, unless it be in some very forcible action, and then too they are to be represented very faintly: the like is also to be observed as to children. The motion of the whole body must be considered in drawing of the muscles; as in the rising and falling of the arms, the muscles of the breast appear either more or less, and it is the same chiefly in the shoulders, sides, and neck, according to the several actions of the body.

The proportion of the figure ought to be multiplied by degrees, in proportion of one to two, three, four, &c. for herein the chief skill consists; and the diameter of the biggest place between the knee and the foot is double the least, and the largest part of the thigh triple.

Of drawing faces.—In drawing a head, it is usually divided into four equal parts: 1. From the crown of the head to the top of the forehead. 2. From the top of the forehead to the eyebrows. 3. From the eyebrows to the bottom of the nose. 4. From hence to the bottom of the chin. But this proportion is not constant; these features, in different men, being very often different as to length and shape. In a well-proportioned face, however, they are nearly right.

To direct you, therefore, in forming a perfect face, your first business is to draw a complete oval, see the Plate XLV. fig. 1. in the middle of which from the top to the bottom, draw a perpendicular line; and through the centre, or middle of this line, draw another, directly across from one side to the other of your oval. On these two lines all the features of the face are to be drawn, as follows. Divide your perpendicular line into four equal parts: the first must be allotted to the hair of the head; the second is from the top of the forehead to the top of the nose, between the eyebrows; the third is from thence to the bottom of the nose; and the fourth includes the lips and chin. The line across the perpendicular one, or

the breadth of the face, is always supposed to be the length of five eyes; you must therefore divide it into five equal parts, and place the eyes upon it so as to leave exactly the length of one eye betwixt them. This is to be understood only of a full front face; for if it turns to either side, then the distances are to be lessened on that side which turns from you, less or more, in proportion to its turning. The top of the ear is to rise parallel to the eyebrows, at the end of the diameter or cross line, and the bottom of it must be equal to the bottom of the nose; the nostrils ought not to come out farther than the corner of the eye in any face; and the middle of the mouth must always be placed upon the perpendicular line. The mouth, when shut, is as large as an eye.

The following is an ingenious device, which perhaps may somewhat assist the young practitioner, in forming the face according to its different turnings, and in placing the features properly thereon. Procure a piece of smooth wood, turned for the purpose, in the shape of an egg, which is nearly the shape of the human head; draw a line lengthways quite round it, as in the last fig. and divide this line into two equal parts by another line drawn directly across it at right angles. The features being drawn on these two lines, according to the rules delivered above, will produce a fore-right face. Turn the oval a small matter from the left hand to the right, and the perpendicular will appear bent like a bow, as you see in fig. 2; upon which the particular features are to be drawn, as in fig. 3. always observing in what manner the nose projects beyond the round of the oval. The same must be observed, if you turn the oval from the right hand to the left, as in fig. 4. and if you incline the oval downwards and to the right, the lines of the cross will appear as in fig. 5. and the features drawn on them as in fig. 6. If you turn it upwards, reclining to the left, the lines of the cross will appear as in fig. 7. and a face drawn on them as in fig. 8. A great variety of faces may be shown by this oval, according as you incline, recline, or turn it, more or less.

But those figures which come sideways are to be drawn by means of a perpendicular, as in fig. 9. upon which the forehead, nose, mouth, and chin, are to be drawn as you see in fig. 10.

It is to be observed, that if the face be fat, the cheeks will seem to swell; if lean, the jaw-bones will stick out, and the cheeks fall in; but if it be neither too fat nor too lean, it will be nearly round.

Touch the features lightly, where the eyes, nose, mouth, and chin, should stand: then begin to draw them more exactly, and so proceed till you have finished the face; after which draw the hair, beard, and shadows about it. You are to consider all those chief touches which give life to a face, and that discover the disposition of the mind: thus the mouth extended, and the corners turning a little up, shows a smiling countenance, &c. You must take care that the shadows are not made too dark where they should be light, because afterwards they cannot be rendered more light: and remember, that they are to be more faint and light in a fair, than in a swarthy complexion.

Of drawing mixed figures.—In order to draw the form of any beast, or bird, you must be well acquainted, as has been remarked, with its shape and actions, without which you will never perform any thing excellent in this way; and whatever beast you draw, you must be sure to give a sketch of the landscape of the country natural to that beast.

In drawing birds, the feathers, beginning at the head very small, must fall backwards one way in five ranks, still increasing till finished.

Insects, as flies, bees, wasps, grasshoppers, worms, and such-like, are drawn with great ease, provided you, for the first time, have the original before your eyes.

In drawing a flower, begin from the rosetuft, or wart in the middle, as in a rose or marigold with the yellow tuft; which being made, draw lines equally divided from thence to the greatest compass or extent of the flower. They may be drawn either fully open, or in the bud; the leaves may be first drawn rudely, afterwards giving them their veins, or jaggedness.

Of drawing landscapes, buildings, &c.—All true drawing consists in nicely measuring the distances of each part of your piece by the eye. In order to facilitate this, you are to imagine in your mind that the peice you copy is divided into squares: as for example; suppose or imagine a perpendicular and an horizontal line crossing each other in the centre of the picture you are to copy: then suppose also two such lines crossing your own copy. Observe in the original what parts of the design those lines intersect, and let them fall on the same parts of the supposed lines in your copy. If you are to draw a landscape from nature, take your station on a rising ground, where you may have a large horizon, and mark your tablet into three divisions downwards, from the top to the bottom; and divide in your own mind the landscape you are to take into three divisions also. Then turn your face directly opposite to the middle of the horizontal line, keeping your body fixed, and draw what is directly before your eyes upon the middle division of your tablet: then turn your head, but not your body, to the left hand, and delineate what you view there, joining it properly to what you had done before. Lastly, do the same by what is to be seen on your right hand, laying down every thing exactly, both with respect to distance and proportion. Make the nearest objects in your piece the highest, and those that are further off to shoot away lower and lower, till they come almost level with the line of the horizon; lessening every thing proportionably to its distance, and observing also, to make your objects fainter and less distinct the farther they are removed from your eye. Make all your lights and shades fall one way; and let every thing have its proper motion, as trees shaken by the wind, the small boughs bending more, and the large ones less; water agitated by the wind, and dashing against ships or boats, or falling from a precipice upon rocks and stones, and spirting up again into the air, and sprinkling all about: clouds also in the air, now gathered with the winds, now violently condensed into hail, rain, and the like; always remembering that whatever motions are caused by the wind must all be made the same way.

Let the work imitate the season it is intended to represent: as, if you intend it for a winter-piece, represent the felling of woods, sliding upon the ice, fowling, hunting, &c. making the trees every where naked, or laden with snow or hoar-frost; the earth bare; the air thick

or heavy; the water frozen, with carts passing over it, &c.

Let every site have its proper adjuncts, or additional graces, as the farm-house, wind-mill, water-mill, woods, flocks of sheep, herds of cattle, pilgrims, ruins of temples, castles and monuments, with a thousand such other things proper to particular subjects.

Of mechanical means for copying drawings.—There are various methods by which those who are ignorant of the art of drawing may copy very accurately the outlines of pictures, prints, and drawings; and these methods are often useful to those who can draw, and to engravers, when either great expedition, or great accuracy, is required; though none of them should ever be used by one who is learning to draw.

Tracing against the light.—Hold the drawing you wish to copy against one of the panes of the window; or have a pane of glass put in a frame, and fitted up like a music-stand, with a candle behind it. Lay your paper over the drawing, and you will see all the lines of the original distinctly through it, by which means you can easily trace them with a pen, or black-lead pencil.

To make tracing-paper.—Mix together equal parts of oil of turpentine and drying oil, and with a rag rub it evenly over some fan or tissue-paper, or any other very thin paper. Hang it by to dry for a day or two, and it will be fit for use. Lay this over the print or drawing you want to copy, and you will see every line distinctly through, so that you can go over it with the black-lead pencil. If you wish to do it in ink, you must mix a little ox's gall with the ink, to make the paper take it, which it would not otherwise do on account of the oil.

To make camp-paper.—Take some hard soap, mix it with lamp-black; make it into the consistence of a jelly with water; with this, brush over one side of your paper, and let it dry. When you use it, put it between two sheets of clean paper, with its black side downwards; and with a pin, or stick with a sharp point, draw or write what you please upon the clean paper; and where the tracer was touched, there will be an impression upon the lowermost sheet of paper as if it had been written or drawn with a pen. It may be made of any colour, by mixing with the soap black-lead, vermillion, &c.

Stenciling.—Lay the print or drawing you wish to have copied over a sheet of paper, and with a pin or needle prick all the outline over with holes, through both the papers. Then take the clean paper with the holes made in it, and lay it upon the paper you wish to have the design transferred to, and dust it over with the powder of charcoal in a small muslin bag; the dust will penetrate through the holes, and leave a correct copy of the original upon the paper.

This pricked paper will do again for any number of copies. This is very useful for ladies who work flowers upon muslin.

The method of enlarging and contracting by squares.—Divide the sides of your original with a pair of compasses into any number of equal parts, and rule lines across with a black-lead pencil from side to side, and from top to bottom. Then having your paper of the size you intend, divide it into the same number of squares, either larger or less, as you would enlarge or contract it. Then placing your original before you, draw, square by square, the several parts, observing to make the part of the figure you are drawing fall into the same part of the squares in the copy as it does in your original. To prevent mistakes, number the squares both of the original and copy. This method is much used by engravers.

To prevent the necessity of ruling across the original, which in some cases may injure it, take a square pane of crown glass, and divide its sides, and also its top and bottom, into equal parts: then from each division draw lines across the glass with lamp-black ground with gum-water, and you will divide the glass into squares. Then lay the glass upon the original which you wish to copy, and having drawn the same number of squares upon your paper, proceed to copy into each square on your paper what appears behind each corresponding square of the glass. Instead of a glass, an open frame with threads stretched across will answer the same purpose.

The pentagraph.—The pentagraph is an instrument, by means of which one may copy, enlarge, or reduce, the outlines of any picture, print, or drawing. It may be had at most mathematical instrument-makers', and is extremely useful for copying plans, maps, and other complicated figures.

Transparencies.—The effect of this kind of daawing, which has lately become very fashionable, though by no means a modern invention, is very pleasing, if managed with judgment, particularly in fire and moonlights, where brilliancy of light and strength of shade are so very desirable.

The very great expense attending the purchase of stained-glass, and the risk of keeping it secure from accident, almost precludes the use of it in ornamenting rooms; but transparencies form a substitute nearly equal, and at a very small expense.

The paper upon which you intend to draw must be fixed in a straining-frame, in order that you may be able to place it between you and the light, when you see occasion in the progress of your work. After tracing in your design, the colours must be laid on in the usual method of stained drawings. When the tints are got in, you must place your picture against the window, on a pane of glass framed for the purpose, and begin to strengthen the shadows with the Indian ink, or with colours, according as the effect requires, laying the colours sometimes on both sides of the paper, to give greater force and depth of colour. The last touches for giving final strength to shadows and forms, are to be done with ivory-black, or lamp-black, prepared with gum-water, as there is no pigment so opaque and capable of giving strength and decision.

When the drawing is finishing, and every part has got its depth of colour and brilliancy, being perfectly dry, you touch very carefully with spirits of turpentine on both sides those parts which are to be the brightest, such as the moon and fire; and those parts requiring less brightness, only on one side. Then lay on immediately with a pencil a varnish, made by dissolving one ounce of Canada balsam in an equal quantity of spirit of turpentine. You must be cautious with the varnish, as it is apt to spread. When the varnish is dry you tint the flame with red lead and gamboge, slightly tinging the smoke next the flame: the moon must not be tinted with colour.

Much depends upon the choice of the subject; and none

is so admirably adapted to this species of effect as the gloomy Gothic ruin, whose antique towers and pointed turrets finely contrast their dark battlements with the pale yet brilliant moon. The effect of rays passing through the ruined windows, half-choaked with ivy; or of a fire among the clustering pillars and broken monuments of the choir, round which are figures of banditti, or others whose haggard faces catch the reflecting light: these afford a peculiarity of effect not to be equalled in any other species of painting. Internal views of cathedrals also, where windows of stained glass are introduced, have a beautiful effect.

The great point to be attained is, a happy coincidence between the subject and the effect produced. The fine light should not be too near the moon, as its glare would tend to injure her pale silver light; those parts which are not interesting should be kept in an undistinguishable gloom, and where the principal light is, they should be marked with precision. Groups of figures should be well contrasted; those in shadow crossing those that are in light, by which means the opposition of light against shade is effected.

Having thus laid down such complete rules of instruction as may enable a young person of genius, in a remote part of the country, to teach himself drawing, we shall subjoin, for his amusement, some curious devices for drawing any object, in its outlines, as exact as nature; with instructions for shadowing, &c. without any regard to the fore-mentioned rules, or any knowledge in the art of drawing.

Take a sheet of the thinnest, or white-brown paper, and brush it over with the oil of turpentine, which will immediately render it transparent: then, after drying the paper in the air, strain it upon a frame, and fix it against the object you design to draw: this done, place right before it a piece of wood with a hole in it, fit for one's eye to look through, and as you meet any outlines of the object on the transparent paper, trace them over with a pencil; by which means you will obtain the just proportion, and true representation of any object in its outlines.

To render this still more pleasing, observe the tracings of your draught, wherever the shades are, and mark them with your pencil; for all the art in the world can never dispose the shades so regularly, as one may touch by this method; but the shades must be drawn quickly after the outlines are drawn, not at different times, because the sun instantly changes them.

Here observe, as in certain objects you will have fainter, stronger, and darker shades, in your remarks of them, to take such memorandums as may direct you how to finish them with Indian ink, or other colour, when you sit down to complete your work. To this end the best way, before you trace out your object, is to prepare three shells or gallipots of Indian ink, mixed with common water, viz. one of a very faint black, one of a middling black, and one of an intense black, numbering them 1, 2, 3; and as you make your observation on the shades of your object, mark upon your draught the same numbers as they happen to appear, so that afterwards you may finish with certainty.

In this regard the transparent paper is of great use; for, being laid upon any paper or print in a loose sheet, all the lines will be seen so perfectly through it, that you may copy them with the greatest ease; and if the print or picture be done by a good master, you can see which lines are strong, which soft, and how to imitate them.

There is yet another way to take views and landscapes, which some prefer to the transparent paper; and that is, either with white or black tiffany or lawn strained upon a frame, and used in the same manner as the paper, excepting that, as the black-lead pencil is used to the paper, on the white tiffany and on the lawn you must use charcoal very soft and finely powdered; but on the black tiffany very tender white chalk is to be used.

Other curious and easy methods of taking views, copying draughts, prints, &c. to the greatest degree of accuracy.

1. A draught may be taken regularly, from a drawing, on transparent paper, as follows: Take a piece of paper of the same size with that of the draught: rub one side of it with some powder of black lead, till it be well and equally blacked, so that a finger, touching it, will hardly be tinged with the blacking; then take the print, and laying the paper underneath it with the black side downwards, upon another piece of white paper of the same size, pin the three together in two or three places: afterwards, take a pin or needle, somewhat blunted at the point, and trace it over the outlines of your picture, which, with a little pressing, will direct the black paper to impress the white, so as to receive every stroke you draw: this done, you may carefully correct what errors you see with your black-lead pencil, cleaning the new-made draught slightly with the crumb of stale bread.

2. As for the draughts taken on tiffany or lawn, they are only to be laid on paper; that is, such as is drawn with charcoal upon white, and that drawn with chalk upon black or blue paper; and then, giving each of them a knock or two with the hammer, the charcoal or the chalk will fall through them upon the papers directly in the lines they were drawn, and give you the true representation of the object drawn from the life, in white lines upon the black paper, and in black lines upon the white.

Then strengthen these shadows of drawings with your black-lead pencil, chalk, or red oker, upon the pieces of paper where they made the marks; for otherwise the lines will easily be rubbed out. But it must be observed, that this amendment is to be made soon after the lines; because those tender draughts will quickly vanish, if care is not taken to strengthen them immediately. You are to begin this operation at the bottom of the drawing.

3. Another way is, by taking a thin piece of paper, and holding it against a glass-window; particularly a sashed one, because the interruption of the lead in the smaller glazed windows will hinder part of the prospect; then draw what you see from the glass, and afterwards the black-lead paper is to be used as directed before.

4. There is another way still, which may be more easy to the hand or arm of a person not accustomed to drawing upon a paper or lawn placed upright, which is by the use of a camera obscura; though to help the

and one may hold a baguette, or such a stick in the left hand as the oil-painters use to rest the right hand upon; or have some other rest made for the right hand, as may be easily screwed up and down at pleasure. But here is this difference still between drawing a piece of perspective, or view, on a transparent paper or lawn placed upright against any object, and drawing by the camera obscura; that such a piece will take in more of the view or object, and from a greater distance; than the camera obscura will: however, the portable camera obscura will, at first, be very easy to the arm of a beginner, by reason the objects appear on an horizontal plane, such as a table; and the hand, having a proper rest, will more easily follow the line represented on the plane with great exactness.

The camera obscura is a machine or apparatus wherein the images of external objects are represented distinctly, and in their genuine colours, either in an inverted or erect situation. This machine may be made as follows: Darken a chamber, one of whose windows looks into a place set with a variety of objects, leaving only one little aperture open in the window. In this aperture fit a lens, either a plane convex one, or one convex on both sides, so as to be the portion of a large sphere. At a due distance, to be determined by experience, spread a paper or white cloth on the wall, unless the wall itself be whitened so as to serve the purpose: and on this the image of the desired objects will be delineated invertedly.

In this case it is not more difficult to draw, or rather copy the objects, though they are reversed, than to draw or copy several things which we see upright on the frames of transparent paper, lawn, or tiffany; for to trace lines will be as easy done one way as the other; and though the objects falling on the paper or cloth will, while you are drawing them, be reversed, it is but turning the paper or cloth upside down, when they are done, and the drawing will be right to the eye. But to obviate this difficulty, let the paper, or what is to receive the objects, be placed against the back of a chair, and let a person look on the several objects represented thereon over the back of the chair, and this will set them right to the eye. Or, if you would rather have the images appear erect, it may be done either by means of a concave lens, or by receiving the image on a plain speculum inclined to the horizon under an angle of 45 degrees, or by means of two lenses included in a draw-tube instead of one.

It is to be observed, that if the aperture does not exceed the bigness of a pea, the objects will be represented thereon, even though there be no lense at all. To render the images clear and distinct, it is necessary that the objects be illuminated by the sun; and they will be still brighter if the spectator first stay a quarter of an hour in the dark.

Care must be likewise taken that no light escape through any chinks, and that the wall be not too much illuminated. Farther, the greater distance there is between the aperture and the wall, the larger and more distinct will the images be; but the rays becoming thus too much dilated, the brightness of the image is weakened, till at length it becomes insensible. But the portable camera obscura is more proper for beginners, as being more easy for their arm; besides, the objects appearing on an horizontal plane, may, of course, be drawn with greater exactness.

The construction of a portable camera obscura may be as follows: Provide a wooden chest, in the middle of which raise a little turret either round or square, open toward the object. Behind this aperture incline a little plain mirror to an angle of 45 degrees, which will reflect the rays upon a lens convex on both sides, included in a tube. At the end of the focus of the lens, place a table covered with a white paper to receive the image; and, lastly, make an oblong aperture to look through. By means of this machine the images will be exhibited perfectly like their objects, each clothed in their different colours; whereby any person, unacquainted with designing or drawing, will be able to delineate any thing to the greatest degree of accuracy and justness; and those even well versed in painting will find many hints by it to perfect them in this art.

5. Two other methods, both easy and entertaining, not hitherto mentioned, for taking of draughts or drawings, are as follow: 1st. Prick with a pin the outlines of the print or drawing you design to copy, and then laying the same on a sheet of paper, take a powder-puff or tuft of cotton, dipping it now and then in charcoal-dust, and beat it over the pricked lines through the picture, by which means you will have full directions marked on your cloth or paper sufficient to finish a just drawing.

2d. The other way is by making such an impression from the print as shall give a just copy of it; and it is of great use when we want to carry every stroke of the graver along with us; which method, if you are very careful, will indeed but very little sully the print.

For this end, take some white or green soap, which mix with such a quantity of water as will bring it to the consistence of a jelly; with this mixture rub the print, and with a wet sponge gently wet the paper designed for receiving the impression; then laying it on the print, cover all with two or three other pieces of dry paper, and rub it very hard all over with any thing that is smooth and polished; and thus the wetted paper will have upon it the reverse of the print you rubbed it upon, with every distinct line in the original, if you have been careful to rub it equally.

Secrets of copying drawings, &c.

To take a drawing with fixed ink.—Take a thin sheet of paper, and rub it all over with fresh butter, as equally as possible, then dry it well by the fire, and rub the buttered side either with carmine, lamp-black, black-lead powder, or blue bice finely ground, till it is all equally coloured; taking care in rubbing on any of these, that the colours will not come off by a very slight touch of the finger. Then lay the coloured side of this buttered paper upon a clean piece of paper, and lay the print you design to copy upon the buttered paper; afterwards with a fine pin or needle, blunted a little at the point, trace the outlines of the drawing carefully, by which means you will have a good copy of it upon your white paper; which may be touched afterwards with crayons, or the like colour.

To take the impression with red ink.—Mix some vermilion finely ground with linseed oil, but not so much

but that it shall still be liquid enough to run or flow in a pen. With this trace the lines of your print; and then with a sponge dipt in water wet the back side of the print, and turn the printed side down upon a piece of white paper, so as to lie smooth: then lay over that a piece of dry paper, and press it hard in every part; and the lower white paper will receive the impression. But if you have a linen-press, it is better to put your papers between two of the leaves, and screw the press as tight as you can, by which means you will have a fine impression.

To take draughts, writings, &c. with red loose ink.—Take some vermilion finely ground, and mix it with fair water in a gallipot with some cotton in it, so that it may run very free in the pen: with this mixture draw over all the strokes of your print, imitating both the finer and stronger lines; then with a sponge dipt in gum-water wet a piece of clean white paper, and while it is wet turn the print upon it; and pressing it well, take off the print, and you will find all the strokes remain on the clean paper; and as soon as it is dry the vermilion will be fixed to it.

This sort of ink has been used frequently in writing any thing designed to be engraved; for by turning the writing side of the paper down upon a copper-plate covered with bees-wax, and white ground, rubbing it very equally, the impression will be upon the wax.

Taking draughts with blue loose ink.—You may likewise make such a sort of ink with blue bice and common water as will run very finely in a pen, and serve for the same use as the former ink.

To take off a drawing in a standing red colour by tracing.—Take vermilion finely ground, and mixing it with a little fresh butter, rub a clean sheet of paper on one side with this mixture; so that it may bear a slight touch of the finger without leaving the paper; then laying the coloured side of this paper upon a clean sheet, lay your print upon the other side of the coloured paper, and then trace every line you think proper, as already directed in tracing a draught with fixed ink: but be sure to pin the three papers together at the corners, to prevent their slipping, which would inevitably spoil your work. This impression made by tracing will hold without rubbing or pressing the papers. The quills of a swallow, after they are thoroughly dry, are very good for tracing.

By mixing carmine with some fresh butter, and colouring a paper with it in the same manner, you will obtain a more beautiful colour; and by colouring a paper in like manner with blue bice and butter, you may have the drawing blue.

To take the natural or lively shape of any herb or tree.—First take the leaf you would copy, and gently rub the veins on the back side of it with a piece of ivory, or some such like matter, so as to bruise them a little; afterwards wet the same side gently with linseed-oil, and then press it hard upon a piece of white paper, and you shall have the perfect figure of the leaf, with every vein in it justly expressed; this impression being afterwards coloured will seem truly natural, and may be useful to such as would remember plants.

Another way of painting the leaves of plants, so that the impression shall appear as black as if it had been done in a printing-press, is as follows.—When the leaf is dry, take such a ball as the pressmen use for blacking the types, and rubbing it equally over with printer's ink, strike it gently four or five times on the back of the leaf, till all the veins are blacked with the ink; then laying the leaf on a flat board or the like, with the back side upwards, lay a piece of white paper well moistened on the leaf; and pressing it pretty hard, but not so as to bruise the fibres, you shall have a fine impression.

But this may be done to still greater advantage by means of a piece of wood in the form of a cylinder, about a foot long, and an inch and a half diameter, the middle part about six or eight inches long, being covered with a woollen cloth rolled three or four times round it. With this cylinder roll the paper over the leaf four or five times backwards and forwards, and you have a curious impression.

But where printer's ink is not conveniently come at, the following method may be made use of: Rub the back of the leaf, as before directed, with burnt linseed oil: then, strewing some powder of black lead, or, for want of that, some charcoal or small-coal dust, or the powder of burnt cork, upon a smooth board, so as equally to cover it, stroke the powder gently over; and oiling the back side of the leaf, clap it upon the board; then laying the white paper upon the back of the leaf, press or roll it as before.

If none of these ingredients are conveniently had, take vermilion, and mixing it with fresh butter in the consistence of printer's ink, cover your printing ball with it; daub it over the back of the leaf, and take your impression as before.

Where vermilion is used, bice may also be made use of, either with butter or oil, by grinding blue bice with some burnt linseed oil, and using it as before: thus you may have a fine red or blue ink, proper for impressions of this sort; but the blue is preferable in colouring leaves, because it is an agreeable colour for the green sort.

It may be observed, that the reason why the back of the leaf is the proper side to make the impression from, is because the ribs or vessels rise on that side above the fleshy part of it; and therefore being coloured with any of those inks, they are the fittest to give an impression; whereas, in the foreside of the leaf, the fleshy parts rise, and these fine fibres are sunk between them.

DREIN, in the military art, a trench made to draw the water out of a moat, which is afterwards filled with hurdles and earth, or with fascines, or bundles of rushes and planks, to facilitate the passage over the mud.

DRESSING *of ores*, the breaking and powdering them in the stamping-mill, and afterwards washing them in a wooden trough.

DRESSING. See SURGERY.

DRIFT *of the forest*, is an exact view and examination taken at certain times to know what beasts are there; in order that none may come on the forest but such as have right, and that the forest be not overcharged with beasts.

DRIFT, in mining, a passage cut out under the earth, betwixt shaft and shaft, or turn and turn; or a passage or way wrought under the earth, to the end of a meer of ground, or part of a meer.

DRIFT, in navigation, the angle which the line of a ship's motion makes with the nearest meridian, when she drives with her side to the wind and waves, and is not governed by the power of the helm; it also implies the distance which the ship drives on that line. A ship's way is only called drift, in a storm; and then it blows so vehemently as to prevent her from carrying any sail, or at least restrains her to such a portion of sail as may be necessary to keep her sufficiently inclined to one side, that she may not be dismasted by the violent labouring produced by the turbulence of the sea.

DRIFT-SAIL, a sail used under water, veered out right ahead by sheets, as other sails are. It serves to keep the ship's head right upon the sea in a storm, and to hinder her driving too fast in a current.

DRILL, in mechanics, a small instrument for making such holes as punches will not conveniently serve for. Drills are of various sizes, and are chiefly used by smiths, turners, carpenters, and coopers.

DRILL, or *drill-box*, a name given to an instrument for sowing land in the new method of horse-hoeing husbandry.

DRILL-*sowing*, a method of sowing grain or seed of any kind, so that it may all be at a proper depth in the earth, which is necessary to its producing healthful and vigorous plants. For this purpose a variety of drill-ploughs have been invented and recommended; but partly from the expense attending the purchase, partly from the complication of their structure, and partly from the attachment of the illiterate farmer to long habits, these excellent schemes for diminishing labour have not received that share of encouragement to which they seem entitled.

DRIVING, in the sea-language, is said of a ship when an anchor being let fall will not hold her fast, nor prevent her sailing away with the tide or wind. The best help in this case is to let fall more anchors, or to veer out more cable; for the more cable she has out, the safer she rides. When a ship is a-hull or a-try, they say she drives to leeward.

DROIT, *jus*, signifies right or law, of which some distinguish six kinds: 1. Jus recuperandi, right of recovery. 2. Jus entrandi, right of entering. 3. Jus habendi, right of having. 4. Jus retinendi, right of retaining. 5. Jus percipiendi, right of receiving. 6. Jus possidendi, right of possessing.

DROIT is also the highest of all real writs; and takes its name of a writ of right, from the greatest regard being shown to it, and as it has the most assured and final judgment. There are several sorts of these writs used in our law, as droit de avowson, droit de dower, droit de garde, droit patent, droit rationabili parte, and droit sur disclaimer.

DROMEDARY, *dromedarius*, a large animal of the camel kind. See CAMELUS.

DRONE, in the history of insects, a kind of bee, larger than the common working or honey bees. See APIS.

DROPS, in meteorology, small spherical bodies which the particles of fluids spontaneously form themselves into, when let fall from any height. This spherical figure, the Newtonian philosophers demonstrate to be the effect of corpuscular attraction; for considering that the attractive force of one single particle of a fluid is equally exerted to an equal distance, it must follow that other fluid particles are on every side drawn to it, and will therefore take their places at an equal distance from it, and consequently form a round superfices. See ATTRACTION, and METEOROLOGY.

DROPSY, in medicine, an unnatural collection of watery humours in any part of the body. See MEDICINE.

DROSERA, or *sun-dew*, a genus of the pentagynia order, in the pentandria class of plants, and in the natural method ranking under the fourteenth order, gruinales. The calyx is quinquefid, the petals five; the capsule unilocular, and quinquevalved at top; the seeds very numerous. There are nine species, two of which grow naturally in boggy places in many parts of the kingdom. They seem to receive the name of sun-dew from a very striking circumstance in their appearance. The leaves, which are circular, are fringed with hairs supporting small drops or globules of a pellucid liquor like dew, which continue even in the hottest part of the day and in the fullest exposure to the sun. The whole plant is acrid, and sufficiently caustic to erode the skin: but some ladies mix the juice with milk, and apply it to remove freckles. The juice that exudes from it unmixed, will destroy warts and corns. The plant has the same effect upon milk as the common butterwort; and like that too is supposed to occasion the rot in sheep.

DROWNING, signifies the extinction of life by immersion in water. In some respects there seems to be a great similarity between the death occasioned by immersion in water, and that by strangulation, suffocation by fixed air, apoplexies, epilepsies, sudden faintings, violent shocks of electricity, or even violent falls and bruises. Physicians, however, are not agreed with regard to the nature of the injury done to the animal system in any or all of these accidents. It is indeed certain, that in all the cases above-mentioned, particularly in drowning, there is very often such a suspension of the vital powers as to us has the appearance of a total extinction of them; while yet they may be again set in motion, and the person restored to life, after a much longer submersion than has been generally thought capable of producing absolute death.

De Haen, in his treatise on this subject, ascribes the diversity of opinion among physicians to their having been so ready to draw general conclusions from a few experiments. Some, having never found water in the lungs, have thought it never was there; and others, from its presence, have drawn a contrary conclusion. Some have ascribed the death which happens in cases of drowning, to that species of apoplexy which arises from a great fulness of the stomach. But this opinion our author rejects, because in 13 dogs which he had drowned and afterwards dissected, no signs of such a fullness appeared. Another reason is drawn from the want of the common marks of apoplexy on the dissection of the brain, and from the actual presence of water in the lungs. He is of opinion, that the death of drowned persons happens in consequence of water getting into the lungs, and stopping the blood in the arteries, and of course that blowing into the lungs must be hurtful, as it will increase the pressure on the blood-vessels.

Dr. Cullen, in his letter on this subject to lord Cathcart, says, that very often the water does not enter the lungs, nor even the stomach, in any material quantity; and, that in most cases, no injury is done to the organization of the vital parts. Hence he argues, that the death which seems to ensue, is owing to the stoppage of respiration, and the consequent ceasing of the circulation of the blood, whereby the body loses its heat and vital principle.

In the Phil. Trans. vol. lxvi. Mr. Hunter advances the following theory.—The loss of motion in drowning seems to arise from the loss of respiration; and the immediate effect this has on the other vital motions of the animal, at least this privation of breathing, appears to be the first cause of the heart's motion ceasing. It is most probable, therefore, Mr. Hunter observes, that the restoration of breathing is all that is necessary to restore the heart's motion; for if a sufficiency of life still remains to produce that effect, we may suppose every part equally ready to move the very instant in which the action of the heart takes place, their actions depending so much upon it. What makes it very probable that the principal effect depends upon throwing air into the lungs, is, that children in the birth, when too much time has been spent after the loss of that life which is peculiar to the fœtus, lose altogether the disposition for the new life: in such cases there is a total suspension of the actions of life; the child remains to all appearance dead; and would die if air was not thrown into its lungs, and the first principle of action by that means restored. To put this in a clearer light, Mr. Hunter gives the result of some cruel and by no means justifiable experiments made on a dog in 1755. A pair of double bellows were provided, which were so constructed, that by one action air was thrown into the lungs, and by the other air was sucked out which had been thrown in by the former, without mixing them together. The muzzle of these bellows was fixed into the trachea of a dog, and by working them he was kept perfectly alive. While this artificial breathing was going on, the sternum was taken off, so that the heart and lungs were exposed to view. The heart then continued to act as before, only the frequency of its action was greatly increased. Mr. Hunter then stopped the motion of the bellows; and observed that the contraction of the heart became gradually weaker and less frequent, till it left off moving altogether; but by renewing the operation, the motion of the heart also revived, and soon became as strong and frequent as before. This process was repeated upon the same dog ten times, sometimes stopping for five or ten minutes. Mr. Hunter observed, that every time he left off working the bellows, the heart became extremely turgid with blood, and the blood in the left side became as dark as that in the right, which was not the case when the bellows were working. These situations of the animal, he observes, seem to be exactly similar to drowning.

Dr. Goodwyn, in a subsequent treatise on this subject, has endeavoured to ascertain the effects of submersion upon living animals in a still more accurate manner; and this investigation is accompanied with a most careful and ingenious inquiry concerning the causes of the different phenomena which he remarked in the course of a great number of experiments. From a review of these Dr. Goodwyn draws the following conclusions: 1. "A small quantity of fluid usually passes into the lungs in drowning. 2. This water enters the lungs during the efforts to inspire; and mixing with the pulmonary mucus, occasions the frothy appearance mentioned by authors. 3. The whole of this fluid in the lungs is not sufficient to produce the changes that take place in drowning. And hence it follows, that the water produces all changes that take place in drowning indirectly, by excluding the atmospheric air from the lungs. This naturally leads to an investigation of the uses of respiration, and the effects of the air upon the blood and lungs in that action. The author begins with attempting to determine the quantity of air drawn in at each inspiration, with the proportional quantity left after expiration. The experiments by which he endeavoured to ascertain these quantities seem to be more uncertain than the others, as indeed there are not data sufficient for them. Concerning the chemical changes produced in the air by respiration, and the effects of the air upon the blood itself, we shall only observe in general, that his experiments evidently show that the disease produced by drowning arises entirely from the exclusion of the atmospheric air or its pure part; for which reason he recommends inflating the lungs with that kind of air in preference to any other.

From these different views of the matter, physicians have differed considerably in their account of the methods to be followed in attempting the recovery of drowned persons. De Haen recommends agitation of all kinds; every kind of stimulus applied to the mouth, nose, and rectum; bleeding; heat, both by warm cloths and warm water; blowing air into the trachea; stimulants, such as blisters, warm ashes, &c. applied to the head, ankles, thighs, pit of the stomach, and other parts. Dr. Cullen's instructions on this subject, however, are of much more importance; but they are detailed too much at length to admit of an adequate abridgement in this article. For every practical purpose, indeed, the plan of recovery distributed by the Royal Humane Society of London is sufficient. It is as follows:

1. As soon as the patient is taken out of the water, the wet clothes, if the person is not naked at the time of the accident, should be taken off with all possible expedition on the spot (unless some convenient house is very near), and a great coat or two, or some blankets if convenient, should be wrapped round the body.

2. The patient is to be thus carefully conveyed in the arms of three or four men, to the nearest public or other house, where a good fire, if in the winter season, and a warm bed, can be made ready for his reception. As the body is conveying to this place, great attention is to be paid to the position of the head; it must be kept supported in a natural and easy posture, and not suffered to hang down.

3. In cold or moist weather, the patient is to be laid on a mattress or bed before the fire, but not too near, or in a moderately heated room: in warm and sultry weather, on a bed only. The body is then to be wrapped as expeditiously as possible with a blanket, and thoroughly dried with warm coarse cloths or flannels.

4. In summer or sultry weather too much air cannot be admitted. For this reason it will be necessary to set

open the windows and doors, as cool refreshing air is of the greatest importance in the process of resuscitation.

5. Not more than six persons are to be present to apply the proper means; a greater number will be useless, and may retard, or totally prevent, the restoration of life, by rendering the air of the appartment unwholesome. It will be necessary, therefore, to request the absence of those who attend merely from motives of curiosity.

6. It will be proper for one of the assistants, with a pair of bellows of the common size, applying the pipe a little way up one nostril, to blow with some force, in order to introduce air into the lungs; at the same time the other nostril and the mouth are to be closed by another assistant, while a third person gently presses the chest with his hands, after the lungs are observed to be inflated. By pursuing this process, the noxious and stagnant vapours will be expelled, and natural breathing imitated. If the pipe of the bellows is too large, the air may be blown in at the mouth, the nostrils at the same time being closed, so that it may not escape that way: but the lungs are more easily filled, and natural breathing better imitated, by blowing up the nostril.

7. Let the body be gently rubbed with flannels, sprinkled with spirits. A warming pan heated (the body being surrounded with flannel) may be lightly moved up and down the back. Fomentations of hot brandy are to be applied to the pit of the stomach, loins, &c. and often renewed. Bottles filled with hot water, heated tiles covered with flannel, or hot bricks, may be efficaciously applied to the soles of the feet, palms of the hands, and other parts of the body. The temples may be rubbed with spirits of hartshorn, and the nostrils now and then tickled with a feather; and snuff, or eau de luce, should be occasionly applied.

8. Tobacco-fumes should be thrown up the fundament; if a fumigator is not at hand, a common pipe may answer the purpose.

The operation should be frequently performed, as it is of importance; for the good effects of this process have been experienced in a variety of instances of suspended animation. But should the application of tobacco-smoke in this way not be immediately convenient, or other impediments arise, clysters of this herb, or other acrid infusions with salt, &c. may be thrown up with advantage.

9. When these means have been employed a considerable time without success, and a brewhouse or warm bath can be readily obtained, the body should be carefully conveyed to such a place, and remain in the bath, or surrounded with warm grains, for three or four hours. If a child has been drowned, its body should be wiped perfectly dry, and immediately placed in bed between two healthy persons. The salutary effects of the natural vital warmth, conveyed in this manner, have been proved in a variety of successful cases.

10. While the various methods of treatment are employed, the body is to be shaken every ten minutes in order to render the process of animation more successful: and children in particular, are to be much agitated, by taking hold of their legs and arms frequently and for a continuance of time. In various instances agitation has forwarded the recovery of boys who have been drowned, and continued for a considerable time apparently dead.

11. If there are any signs of returning life, such as sighing, gasping, or convulsive motions, a spoonful of any warm liquid may be given: and if the act of swallowing can be performed, a cordial of warm brandy or wine may be given in small quantities and frequently repeated.

12. Electricity may be tried by the judicious and skilful, as its application neither prevents nor retards the various modes of recovery already recommended; but, on the other hand, will most probably tend to render the other means employed more certainly and more expeditiously efficacious. This stimulus promises to prove an important auxiliary in case of apparent death, and therefore deserves the serious regard and attention of the faculty.

The methods which have been described, are to be employed with vigour for three hours or upwards, although no favourable circumstances should arise; for it is a vulgar and dangerous error to suppose that persons are irrecoverable because life does not soon make its appearance; an opinion that has consigned to the grave an immense number of the seemingly dead, who might have been restored to life by resolution and perseverance. Bleeding is never to be employed in such cases, unless by direction of one of the medical assistants, or some other gentleman of the faculty who has paid attention to the resuscitating art.

We shall now describe the apparatus made use of in recovering bodies from the water, and in restoring suspended animation.

Pl. LIII. Mis. fig. 44, is a forked instrument with blunt points for making superficial search after the drowned body, sounding the particular situation in which it sunk.

Fig. 45, a ladder with a long jointed handle.

Fig. 46, an extractor, or a linked pair of tongs, which in the plate appears closed; but on immersing it into water, opens by its own weight, as well as by the sliding down of the iron ring *o* from the part marked *x* to that of *u*. It may again be closed by pulling the double rope fastened to the ring *o*, which is thus shifted upward from *u* to *x*: by means of expanding the iron arms *n n*, which are likewise connected with this ring, the mouth or flaps of the instrument *rr* may be shut; and to prevent their opening till required, the two ropes are firmly tied round the iron bolt *ss*, in which situation they remain till the body is extracted. Great attention is required in preserving them from the effects of rust; and, independantly of the weight of iron work, it is perhaps the most complete piece of machinery that can be contrived for this purpose.

Fig. 47, a pair of bellows with two separate bags, so contrived that by opening them when applied to the nostrils or mouth of a patient, one bag will be filled with common air, and the other with the air extracted from the longs; and by shutting them again, pure atmospheric air will be introduced into these organs, and that drawn out consequently discharged into the room. Thus the artificial breathing may be continued, while the other operations on the surface of the body are carried on: which could not be conveniently done if the muzzle of a common pair of bellows were introduced into the nostril.

a, Is an intermediate board, but which admits of no communication between the two bags. In the external board of each side, there is the usual hole, marked *b*, provided with a valve; and the cylindrical part through which the air is expelled in common bellows, is here soldered to a copper box, within which two other valves are applied to the tubes conducting the air. The cover *d* of this box, may be unscrewed by means of an interposed leather ring, almost of the shape of a funnel, to the neck of which is fastened a flexible tube, *e*, made of varnished silk cloth, and a spiral wire that forms the cavity. To the extremity of this tube is attached a small ivory pipe *f*, the front of which may either be tubular and round, for introducing it into the nostril, or flat, like the top-piece of a clarionet, if it is intended for the mouth. The valves (which cannot be represented in a plate) consist of stiffened taffety, and are so arranged, that the corresponding ones stand in an inverted order. If therefore both bags of the bellows are expanded, two of the valves open themselves towards the internal part of the machine: one of these is fixed to one of the side boards, but the other is within the box, on the mouth of the conducting tube belonging to the opposite bag of the bellows. By this contrivance, the air enters both bags of the bellows at the same time, and is, on compression, again expelled by means of two other valves, which open from within towards the external parts. Both bags of the bellows terminate below the valve in one principal tube of communication; because, though the action of both bellows is simultaneous, the stream of air conformably to the arrangement before pointed out, can only enter and escape alternately. In using this machine, the small ivory pipe is applied either to one of the nostrils, or put into the mouth: in the former case, the other nostril and the mouth must be closed; in the latter, both nostrils. When the bellows are set in action, one of the bags receives a column of atmospheric air through its valve, while the other, by means of its flexible tube and its valve, extracts a portion of air from the lungs. But if the bellows are again shut, one of the bags parts with the impure gas drawn out of the pulmonary vessels, and the second conveys pure atmospheric air to the organs of respiration. By properly repeating this alternate process, the patient may again be enabled to exercise the important function of breathing. As, however, a precipitate and irregular method of proceeding might be productive of injury, this delicate operation ought to be performed by persons who are acquainted with the mechanism of respiration. In some cases, where the patient has, for a considerable time, lain under water, or was afterwards neglected for want of due assistance, it would be desirable to introduce into his lungs oxygen, or pure vital dephlogisticated air, instead of that of the common atmosphere; as the latter is generally more or less corrupted on such occasions hy the breath of many persons in the same room. For this purpose may be used a bladder, marked *g*, which is provided with a cock and pipe fitted or screwed to the board of the inspiring valve and bag of the bellows. If, therefore, after opening the cock, the machine is set in motion, it will extract the pure air contained in the bladder, and, on the subsequent compression of the bellows, force it into the lungs of the patient.

Fig. 48, is a machine for injecting the smoke of tobacco by way of clyster, in those desperate cases which require the application of this remedy. It consists of a pair of bellows, to the muzzle of which is fitted a metal box *a*, provided with a ring, in the middle of which it may be unscrewed, and again closed, after being filled with tobacco, and set on fire; the pipe *c* of the flexible tube *b*, is introduced into the fundament, and thus by means of the bellows *d*, the smoke is forced into the rectum. To these may be added,

A bier of wicker-work, in the form of a slanting oblong basket, for conveying the body of the drowned, in a posture somewhat raised. This simple contrivance has the advantage, that the water may easily run off, while the patient is carried: and as many unfortunate persons are materially injured by rough treatment, before they arrive at a house of reception, so that their recovery is thus often frustrated, we recommend the universal adoption of this useful implement.

The Royal Humane Society of London have, for a series of years, offered premiums for machines and other inventions to save mariners and other persons from drowning in case of shipwreck, or other accidents at sea. The life-boat of Mr. Greathead has been already described under the article Boat; but at the last anniversary (April 15th, 1806), a model of a life-boat was exhibited which may be put together in the space of half an hour, in any case of shipwreck, and which cannot sink or overset, let the sea run ever so high. All that is necessary to be provided with is, a keel or plank of any convenient length, and a few pigs of iron (such as vessels commonly carry out for ballast). The officers of the ship are to take care to keep two or three empty water-casks, perfectly tight, the bungholes corked up, and a piece of tin or leather nailed over them. These casks are to be lashed with ropes to the keel, along with the pigs of iron for ballast; and any spare poles or spars may be also lashed to the sides, so as to give the raft the form of a vessel, and at each end to make a lodgment for the men. Any of the square sails of the ship will form a lug-sail, and may speedily be adapted to the new life-boat; and a strong and broad spar may be lashed on as a rudder. Several inventions have also been recommended by the committee of the society to enable persons to swim from a wreck to the shore; particularly the cork or marine spencer, already noticed under the article Cork, and "the life-preserver" invented by Mr. Daniel, of Wapping. This last is a machine of water-proof leather, which wraps round the body just under the armpits, and is inflated like a bladder in the space of half a minute, by blowing with the breath through a silver tube, furnished with a stop-cock, which is to be turned when the machine is full of air.

The immediate views of this committee of the Royal Humane Society for affording assistance and preventing shipwreck, are clearly developed in their resolutions of the 19th March 1798, which in the hope of exciting the attention of scientific men to so interesting a subject we insert.

"Resolved, That it is the opinion of this committee,

"I. That means may be contrived for preventing vessels which are light and of particular importance, such as packets, from foundering at sea, by means of a thick lining of cork or very light timber, which may prevent the

vessel from sinking in case of any of her planks starting, or other accidents happening to the hull.

"II. That, in case of shipwreck, the grand object is to form a communication with the shore: and it appears to this committee, that the most probable means of effecting this object is, to convey a rope or line by some projectile force to the nearest land; and that, the more simple the machine for this purpose (having ample power), the more likely it is to have a proper practical effect.

III. "That the construction of life-boats to go from the shore to a vessel wrecked or in distress (which life-boats ought to be lined with cork or light timber, so as to keep buoyant in almost all cases), is a most laudable and excellent invention; and this committee cannot but hope, that, if this plan was universally adopted on all our sea-coasts, at least wherever it is practicable, it would save the lives of numbers of mariners, and other persons valuable to society.

"IV. That the institution of a body of watermen ready to venture, on all occasions of shipwreck, in life-boats, or other vessels, to assist persons in distress, would be extremely useful. That such persons should have particular privileges, as protections from being impressed, and perhaps badges such as the firemen in London, and should be encouraged by the prospect of rewards to adventure on all such occasions.

DRUG, among fan-makers, is a composition of gum arabic, and some other ingredients, used in laying gold or silver leaf upon fans, or in covering them with either of these metals in powder. They use it also to paste together the papers, gauzes, taffetas, and other matters, used by them in their fans.

Drug signifies also a salt, or cinder of glass, used by some in bleaching cloth. The use of this drug is prohibited in France, as being found corrosive, destructive of the linen, and likely to injure the health of those who use it.

DRUGGET, in commerce, a stuff sometimes all wool, and sometimes half wool half thread, sometimes corded, but usually plain.

DRUIDS, the priests or ministers of religion of the ancient Britons and Gauls. The Druids were chosen out of the best families; and were held, both by the honours of their birth, and their office, in the greatest veneration. They are said to have understood astrology, geometry, natural history, politics, and geography: they had the administration of all sacred things, were the interpreters of religion, and the judges of all affairs indifferently.

DRUM, is a martial musical instrument in form of a cylinder, hollow within, and covered at the two ends with vellum, which is stretched or slackened at pleasure by the means of small cords and sliding knots. Some drums are made of brass, but they are commonly of wood.

There are several beats of the drum, as assembly, chamade, reveille, retreat, &c.

Drums, *kettle*, are large basons of copper or brass, rounded in the bottom, and covered with vellum or goat-skin, which is kept fast by a circle of iron, and several holes fastened to the body of the drum, and a like number of screws to screw up and down. They are much used among the horse, as also in operas, oratorios, concerts, &c.

DRUNGUS, a name given in the latter times of the Roman empire to a body of troops, amounting to from one thousand to four thousand men. At first it was used to denote the troops of strangers and enemies, but in the eastern empire to signify the troops of the empire itself.

DRUNKENNESS, excuses no crime; but he who is guilty of any crime whatever, through his voluntary drunkenness, shall be punished for it as much as if he had been sober; for the law, seeing how easy it is to counterfeit this excuse, and how weak an excuse it is (though real,) will not suffer any man thus to privilege one crime by another. 4 Black. 26.

By several statutes temp. Jac. every person convicted of drunkenness shall forfeit 5*s*. or be committed to the stocks for six hours, and offending a second time, shall be bound in a recognizance of 10*l*. for future good behaviour. And an alehouse-keeper convicted of drunkenness, shall besides the other penalties, be disabled to keep any such alehouse for three years.

DRUPA, or *druppa*, in botany, a species of pericarpium, or seed-vessel, which is succulent or pulpy, has no valve or external opening like the capsule and pod, and contains within its substance a stone or nut. The cherry, plum, peach, apricot, and all other stone-fruit, are of this kind. The term, which is of great antiquity, is synonimous to Tournefort's fructus mollis ossiculo, "soft fruit with a stone;" and to the prunus of other botanists. The stone or nut, which in this species of fruit is surrounded by the soft pulpy flesh, is a kind of ligneous or woody cup, which contains a single kernel or seed. This definition, however, will not apply to every seed-vessel denominated drupa in the Genera Plantarum. The almond is a drupa, so is the seed-vessel of the elm-tree and the genus rumphia, though far from being pulpy or succulent; the first and third are of a substance like leather, the second like parchment. The same may be said of the walnut, pistachio-nut, guettarda, quisqualis, jack-in-a-box, and some others. Again, the seeds of the elm, schrebera, flagellaria, and the mango-tree, are not contained in a stone. The seed-vessel of burr-reed is dry, shaped like a top, and contains two angular stones.

DRYADS, in the heathen theology, deities, or nymphs, which the ancients thought inhabited groves and woods. They differed from the hamadryades, these latter being attached to some particular tree, with which they were born, and with which they died; whereas the dryades were goddesses of trees and woods in general.

We likewise find mention made of a kind of prophetesses, or witches, among the Gauls, called the dryades or druides.

DRYANDRIA, a genus of the class and order diœcia monadelphia. The calyx is two-leaved; corolla five-petalled; stamina nine; fruit three or four grained. There is one species, a dwarf tree of the Mauritius.

DRYAS. a genus of the icosandria-pentagynia class of plants, the flower of which consists of eight oblong, emarginated, patent petals, inserted into the cup. There is no pericarpium, but the seeds are numerous, of a roundish compressed figure, and furnished with very long hairy styles. There are two species.

DRYPIS. a genus of the class and order pentandria trigynia. The calyx is five-toothed; petals five; capsule

clipped round. one-seeded. There is one species, a shrubby plant of Barbary.

DUCAT, a coin current in Germany, and other countries abroad, for the different values of which see COIN.

DUCATOON, a silver coin, likewise frequent in several parts of Europe.

DUCENARIUS, in Roman antiquity, a military officer who had the command of two hundred men. The title ducenarii is also given to certain procurators of the emperors, so called either from their having a salary of 200 sesterces, or from their being appointed to raise the tax of the two-hundredth penny.

DUCES TECUM, in law, a writ that commands a person to appear in the court of chancery, and bring with them certain writings, evidences, or other things, which the court is inclined to view.

DUCES *tecum licet languidus*, in law, is a writ directed to the sheriff, on a return that he is not able to bring his prisoner without danger of death, he brings adeo languidus; upon which the court grants a habeas corpus, in nature of a duces tecum licet languidus.

DUCK. See ANAS.

DUCKING, plunging in water, a diversion anciently practised among the Goths, by way of exercise; but among the Celtæ, Franks, and ancient Germans, it was a sort of punishment for persons of scandalous lives. They were shut up, naked to the shift, fastened to the yard of a shallop, and ducked several times.

DUCKING *at the main yard*, among seamen, is a way of punishing offenders on board a ship; and is performed by binding the malefactor, by a rope, to the end of the yard, whence he is violently let down into the sea, once, twice, or three times, according to his offence: and if the offence is very great, he is drawn underneath the keel of the ship, which they call keel-haling.

DUCK-UP, at sea, is a term used by the steersman, when the mainsail, foresail, or spritsail, hinders his seeing to steer by a land-mark: upon which he calls out, "Duck up the clew-lines of these sails," that is, hale the sails out of the way. Also, when a shot is made by a chace-piece, if the clew of the spritsail hinders the sight, they call out, "Duck-up," &c.

DUCT, *ductus*, in general, denotes any tube or canal. See ANATOMY.

DUCTILITY, in physics, a property of certain bodies, whereby they are capable of being expanded, or stretched forth, by means of a hammer, press, &c. See MECHANICS.

The great ductility of some bodies, especially gold, is very surprising: the gold-beaters and wiredrawers furnish us with abundant proofs of this property; they every day reduce gold into lamellæ inconceivably thin, yet without the least aperture or pore discoverable, even by the microscope: a single grain of gold may be stretched under the hammer, into a leaf that will cover a house, and yet the leaf remain so compact as not to transmit the rays of light, nor even admit spirit of wine to transude. Dr. Halley took the following method to compute the ductility of gold: he learned from the wiredrawers, that an ounce of gold is sufficient to gild, that is, to cover or coat, a silver cylinder of forty-eight ounces weight, which cylinder may be drawn out into a wire so very fine, that two yards shall weigh only one grain; and consequently ninety-eight yards of the same wire, only forty-nine grains: so that a single grain of gold here gilds ninety-eight yards; and, of course, the ten-thousandth part of a grain is here above one-third of an inch long. And since the third part of an inch is yet capable of being divided into ten lesser parts visible to the naked eye, it is evident that the hundred-thousandth part of a grain of gold may be seen without the assistance of a microscope. Proceeding in his calculation, he found, at length, that a cube of gold, whose side is the hundredth part of an inch, contains 2,433,000 visible parts; and yet, though the gold with which such wire is coated, is stretched to such a degree, so intimately do its parts cohere, that there is not any appearance of the colour of the silver underneath.

Mr. Boyle, examining some leaf-gold, found that a grain and a quarter in weight took up an area of fifty square inches; supposing therefore the leaf divided by parallel lines 100th part of an inch apart, a grain of gold will be divided into five hundred thousand minute squares, all discernible by a good eye; for the same author shows, that an ounce of gold drawn out in wire would reach 155 miles and a half.

But Mr. Reaumur has carried the ductility of gold to a still greater extent. What is called gold-wire, every body knows, is only a silver one gilt. The cylinder of silver, covered with leaf-gold, they draw through the hole of an iron, and the gilding still keeps pace with the wire, stretch it to what length they can. Now Mr. Reaumur shows, that in the common way of drawing gold-wire, a cylinder of silver twenty-two inches long, and fifteen lines in diameter, is stretched to 1,163,520 feet, or is 634,692 lines longer than before, which amounts to about ninety-seven leagues. To wind this thread on silk for use, they first flatten it, in doing which it stretches at least one-seventh farther, so that the twenty-two inches, are now 111 leagues; but in the flattening, instead of one-seventh, they could stretch it one-fourth, which would bring it to 120 leagues. This appears a prodigious extension, and yet it is nothing to what this gentleman has proved gold to be capable of.

DUCTILITY *of glass*. We all know that, when well penetrated with the heat of the fire, the workmen can figure and manage glass like soft wax; but what is most remarkable, it may be drawn, or spun out, into threads exceedingly long and fine.

Our ordinary spinners do not form their threads of silk, flax, or the like, with half the ease and expedition as the glass-spinners do threads of this brittle matter. We have some of them used in plumes for children's heads, and divers other works, much finer than any hair, and which bend and wave like hair with every wind.

Nothing is more simple and easy than the method of making them. There are two workmen employed; the first holds one end of a piece of glass over the flame of a lamp; and, when the heat has softened it, a second operator applies a glass hook to the metal thus in fusion; and, withdrawing the hook again, it brings with it a thread of glass, which still adheres to the mass: then, fitting his hook on the circumference of a wheel about two feet and a half in diameter, he turns the wheel as fast as he pleases: which, drawing out the thread, winds

it on its rim; till, after a certain number of revolutions, it is covered with a skein of glass thread.

The mass in fusion over the lamp diminishes insensibly; being wound out like a clue of silk upon the wheel; and the parts, as they recede from the flame, cooling, become more coherent to those next to them, and this by degrees: the parts nearest the fire are always the least coherent, and, of consequence, must give way to the effort the rest make to draw them towards the wheel.

The circumference of these threads is usually a flat oval, being three or four times as broad as thick: some of them seem scarcely bigger than the thread of a silkworm, and are surprisingly flexible. If the two ends of such threads are knotted together, they may be drawn and bent, till the aperture, or space in the middle of the knot, does not exceed one-fourth of a line, or one-forty-eighth of an inch, in diameter.

Hence M. Reaumur advances, that the flexibility of glass increases in proportion to the fineness of the threads; and that, probably, had we but the art of drawing threads as fine as a spider's web, we might weave stuffs and cloths of them for wear. Accordingly, he made some experiments this way; and found that he could make threads fine enough, viz. as fine, in his judgment, as spider's thread, but he could never make them long enough to do any thing with them.

DUEL, a single combat, at a time and place appointed, in consequence of a challenge. This custom came originally from the northern nations, among whom it was usual to decide all their controversies by arms. Both the accuser and accused gave pledges to the judges on their respective behalf; and the custom prevailed so far amongst the Germans, Danes, and Franks, that none were excused from it but women, sick people, cripples, and such as were under twenty-one years of age, or above sixty. Even ecclesiastics, priests, and monks, were obliged to find champions to fight in their stead. The punishment of the vanquished was either death by hanging or beheading, or mutilation of members, according to the circumstances of the case. Duels were at first admitted not only on criminal occasions, but on some civil ones for the maintenance of rights to estates: in latter times, however, before they were entirely abolished, they were restrained to these four cases: 1. That the crime should be capital. 2. That it should be certain the crime was perpetrated. 3. The accused must, by common fame, be supposed guilty. And, 4. The matter not capable of proof by witnesses. In England, though the trial by duel is disused, the law on which it is founded is still in force.

DUELLING, or single combat, between any individuals of their own heads, and for private malice or displeasure, is now prohibited by law; for in a settled state governed by law, no man, for any injury whatever, ought to use private revenge. 3 Inst. 157.

And where one party kills the other, it comes within the notion of murder, as being committed by malice aforethought; where the parties meet with an intent to murder, thinking it their duty as gentlemen, and claiming it as their right to wanton with their own lives, and the lives of others, without any warrant for it either human or divine; and therefore the law has justly fixed on them the crime and punishment of murder. 4 Black. 199.

And the law so far abhors all duelling in cold blood, that not only the principal, who actually kills the other, but also his seconds, are guilty of murder, whether they fought or not; and it is holden that the seconds of the party slain are likewise guilty as accessaries. 12 Haw. 8.

DUETT, a composition expressly written for two voices or instruments, with or without a bass and accompaniments. In good duetts, the execution is pretty equally distributed between the two parts; and the melodies so connected, intermingled, and so dependant on each other, as to lose every effect when separated, but to be perfectly related and concinnous when heard together. Yet, however combined by the disposition of the harmony, the parts are not necessarily to be similar in their motion; indeed it is when the composer is sufficiently master of his art to be able to vary them by contrary directions, that the happiest effects of which this species of composition is capable are most frequently produced.

DUKE, is either the title of a sovereign prince, as the duke of Savoy, Parma, &c. the grand-duke of Tuscany, &c. or it is the title of honour and nobility next below princes. The commanders of armies in time of war, the governors of provinces, and wardens of marches, in time of peace, were called duces, under the latter emperors. The Goths and Vandals divided all Gaul into duchies and counties, the governors of which they sometimes called duces, and sometimes comites. In France, under the second race of kings, though they retained the name and form of ducal government, there were scarcely any dukes except those of Burgundy, Aquitaine, and France.

In England, among the Saxons, the commanders of armies, &c. were called dukes, duces, without any addition, till Edward III. made his son, the Black Prince, duke of Cornwall; after whom there were more made in the same manner, the title descending to their posterity. Duke, at present in England, is a mere title of dignity, without giving any domain, territory, or jurisdiction over the place whence the title is taken. A duke is created by patent, cincture of sword, mantle of state, imposition of a cap and coronet of gold on his head, and a verge of gold put into his hand. His title is Grace; and in the style of the heralds, Most high, potent, high-born, and noble prince.

DULCIMER, a triangular instrument, strung with about fifty wires cast over a bridge at each end; the shortest, or most acute of which, is eighteen inches long, and the longest, or most grave, thirty-six. It is performed upon by striking the wires with little iron rods. This name is also given by the translators of holy writ to an instrument used by the Hebrews, concerning the form, size, and tone of which, there have been various conjectures, but of which nothing certain is known.

DULCINO, the name formerly given to a certain small bassoon, which was used as a tenor to the hautboy.

DULEDGE, in gunnery, a peg of wood which joins the ends of the six felloes that form the round of a wheel of a gun-carriage. The plate of iron on the outside of the wheel, which strengthens the joint, is called the duledge-plate.

DUMBNESS, the privation of the faculty of speech. The most general, and frequently the sole cause of dumbness, is the want of the sense of hearing (see DEAFNESS); language being originally acquired by imitating articulate sounds. From this source of intelligence deaf people are entirely excluded: they cannot acquire articulate sounds by the ear: unless, therefore, articulation can be communicated to them by some other medium, these unhappy people must for ever be deprived of the use of language; and as language is the principal source of knowledge, whoever has the misfortune to want the sense of hearing, must remain in a state little superior to that of the brute creation. Of late years, however, it has been shown, that although deaf people cannot learn to speak or read by the direction of the ear, there are other sources of imitation, by which the same effect may be produced. The organs of hearing and speech have little or no connection. Persons deprived of the former generally possess the latter in such perfection, that nothing further is necessary, in order to make them articulate, than to teach them how to use these organs. This indeed is no easy task; but the regular seminaries kept near the metropolis, by the late Mr. Braidwood and Mr. Telfair, in which the instruction of deaf and dumb persons has been successfully conducted, show that it is certainly practicable. The former began with a single pupil in 1764: and since that period has taught great numbers to speak so as to be understood, to read, to write, to understand figures, the principles of religion and morality, &c.

The first thing attempted in the practice of his method is, to teach the pupil to pronounce the simple sounds of the vowels and consonants. The teacher pronounces the sound of the letter *a* very slowly, pointing out the figure of it upon paper at the same time; and makes the pupil observe the motion of his mouth and throat. He then puts his finger into his pupil's mouth, depresses or elevates the tongue, and makes him keep the parts in that position; then he lays hold of the outside of the throat, and applies such a kind of pressure as shall indicate to the pupil a certain necessary action to be performed by the muscles. All the while he is pronouncing *a*, the pupil is anxiously imitating him, but at first seems not to understand what he would have him to do. In this manner he proceeds, till the pupil has learned to pronounce the sounds of the letters. He goes on in the same manner to join a vowel and a consonant, till at length the pupil is enabled both to utter distinct words, and to read.

The pupils instructed in these academies are not only taught the mere pronunciation, but also to understand the meaning of what they read. Of this Mr. Pennant gives a remarkable instance in a young lady of about 13, who had been some time under the care of Mr. Braidwood. "She readily apprehended (says he) all I said, and returned me answers with the utmost facility. She read; she wrote well. Her reading was not by rote. She could clothe the same thoughts in a new set of words, and never vary from the original sense. I have forgotten the book she took up, or the sentences she made a new version of, but the effect was as follows:

"*Original passage.* Lord Bacon has divided the whole of human knowledge into history, poetry, and philosophy; which are referred to the three powers of the mind, memory, imagination, and reason.

"*Version.* A nobleman has parted the total, or all of man's study or understanding, into—An account of the life, manners, religion, or customs of any people or country; verse or metre; moral or natural knowledge: which are pointed to the three faculties of the soul or spirit; the faculty of remembering what is past, thought or conception, and right judgment."

A new and different method, equally laborious and successful, has been practised by the abbe' de l'Epe'e, of Berlin, who, it is said, begins his instructions not by endeavouring to form the organs of speech to articulate sounds, but by communicating ideas to the mind by means of signs and characters: to effect this, he writes the names of things; and, by a regular system of signs, establishes a connection between these words and the ideas to be excited by them. After he has thus furnished his pupils with ideas, and a medium of communication, he teaches them to articulate and pronounce, and renders them not only grammarians but logicians. In this manner he has enabled one of his pupils to deliver a Latin oration in public, and another to defend a thesis against the objections of one of his fellow-pupils in a scholastic disputation, in which the arguments of each were communicated to the other, but whether by signs or in writing is not said; for it does not appear that the abbe' teaches his pupils to discern what is spoken, by observing the motion of the organs of speech, which those instructed by other teachers do very readily.

There is perhaps no word, says the abbe', more difficult to explain by signs than the word croire, "to believe." To do this, he writes the verb with its significations in the following manner:

Je croie, Je dis oui par l'esprit, Je pense que oui.
Je dis oui par le cœur, J'aime a penser qne oui.
Je dis oui par la bouche.
Je ne vois pas des yeux.

After teaching these four significations, which he does by as many signs, he connects them with the verb, and adds other signs to express the number, person, tense, and mood, in which it is used. If to the four signs corresponding with the lines abovementioned, be added that of a substantive, the pupil will write the word foi, "faith;" but if a sign, indicating a participle used substantively, be adjoined, he will express la croyance, "belief;" to make him write croyable, "credible," the four signs of the verb must be accompanied with one that indicates an adjective terminating in *able*; all these signs are rapidly made, and may be immediately comprehended.

M. Linguet, a member of the Royal Academy, having asserted that persons thus instructed could be considered as little more than automata, the abbe' invited him to be present at his lessons, and expressed his astonishment that M. Linguet should be so prejudiced in favour of the medium by which he had received the first rudiments of knowledge, as to conclude that they could not be imparted by any other: desiring him, at the same time, to reflect, that the connection between ideas and the articulate sounds, by which they are excited in the mind, is not less arbitrary than that between these ideas and the written characters which are made to represent them to the eye. M. Linguet complied with

the invitation; and the abbe' having desired him to fix on some abstract term which he would by signs communicate to his pupils, he chose the word "unintelligibility;" which, to his astonishment, was almost instantly written by one of them. The abbe' informed him, that to communicate this word he had used five signs, which, though scarcely perceivable to him, were immediately and distinctly apprehended by his scholars: the first of these signs indicated an internal action; the second represented the act of a mind that reads internally, or, in other words, comprehends what is proposed to it; a third signified that such a disposition is possible; these, taken together, form the word "intelligible:" a fourth sign transforms the adjective into the substantive; and a fifth, expressing negation, completes the word required. M. Linguet afterwards proposed this question, "What do you understand by metaphysical ideas?" which being committed to writing, a young lady immediately answered on paper in the following terms: "I understand the ideas of things which are independent of our senses, which are beyond the reach of our senses, which make no impression on our senses, which cannot be perceived by our senses."

DUMBNESS, *periodical*. In the German Ephemerides is an account of an innkeeper's son affected with a periodical dumbness, which had continued for fifteen years. The loss of speech was at first instantaneous, and continued only a few minutes; but the duration of it began to lengthen every day: so that it soon amounted to half an hour, two hours, three hours, and at last to 23 hours, yet without any order. At last the return of speech kept so constant and regular an order, that, for 14 years together, he could not speak except from noon, during the space of one entire hour, to the precise moment of one o'clock. Every time he lost his speech, he felt a sense of something rising from his stomach to his throat, but in other respects was in good health. Both his internal and external senses also continued sound: he heard always perfectly well, and answered the questions proposed to him by gestures or in writing. The account states, that all suspicion of imposture was removed by his keeping exactly the same hour, though he had no access to any instruments by which time can be measured.

DUM FUIT INFRA ÆTATEM, a writ that lies for him, who, before he came to his full age, made a feoffment of his land in fee, or for a term of life, or in tail, to recover them again from him to whom he conveyed them.

DUM NON FUIT COMPUS MENTIS, a writ that lies against the alienee, or lessee, for him that not being of sound memory, aliened any lands or tenements in fee-simple, fee-tail, or for term of life, or for years.

DUNG-MEERS, in husbandry, places where soils and dungs are mixed and digested together. For this purpose it is usual to dig a pit sufficient to hold the stock of soil the husbandman is capable of making; and to prepare it at the bottom with stone and clay, that it may hold water, or the moisture of the dung; and besides, it should be so situated that the sinks and drips of the houses and barns may run into it. Into this pit they cast refuse-fodder, litter, dung, weeds, &c. where they lie and rot together, till the farmer has occasion for it. Where such a pit is wanting, it is proper to cover the dung with turf, or other stuff, to prevent the sun and wind from drawing off its virtues. See HUSBANDRY.

DUODENUM, in anatomy, the first of the small guts, intestina tenuia, so called from its length, which is about twelve fingers breadth.

DUPLE, among mathematicians, denotes the ratio of 2 to 1. Thus the ratio of 8 to 4 is duple, or as 2 to 1.

Sub-DUPLE RATIO is just the reverse of the former, or as 1 to 2. Such is 4 to 8, or 6 to 12.

DUPLICATE, among lawyers, denotes a copy of any deed, writing, or account. It is also used for the second letters patent, granted by the lord chancellor in a case wherein he had before done the same. Also, a second letter written and sent to the same party and purpose as a former, for fear of the first's miscarrying, is called a duplicate.

DUPLICATE PROPORTION OR RATIO, is a ratio compounded of two ratios: thus, the duplicate ratio of a to b, is the ratio of a a to b b, or of the square of a to the square of b. Hence the duplicate ratio ought to be well distinguished from double.

In a series of geometrical proportionals, the first term to the third is said to be in a duplicate ratio of the first to the second: thus in 2, 4, 8, 16, &c. the ratio of 2 to 8 is duplicate of that of 2 to 4, or as the square of 2 to the square of 4. Duplicate ratio is therefore the proportion of squares, as triplicate is of cubes, &c. and the ratio of 2 to 8 is said to be compounded of that of 2 to 4, and of 4 to 8.

DUPLICATION, in general, signifies the doubling of any thing, or multiplying of it by 2: also the folding of any thing back again on itself.

The duplication of a cube is a problem famous in antiquity: it was proposed by the oracle at Delphos, as a means to stop the plague, to double Apollo's altar, which was cubical. See CUBE.

DUPLICATURE, among anatomists, a term used to denote the folds of any membrane, or vessel: thus we say, the duplicatures of the intestines, peritonæum, &c. See ANATOMY.

DUPONDIUS, in antiquity, the weight of two pounds; also a piece of money equal to two ases in value.

DURA MATER, in anatomy, one of the membranes, as they are called, which surround the brane.

DURATE', in music, a term properly applicable to whatever offends the ear by its effect. The B natural, on account of its hardness, was formerly called B durate'. There are rough or hard intervals in melody; such are those produced by the regular series of three whole tones, whether ascending or descending, and such are all false relations.

DURANTA, a genus of the angiospermia order, in the didynamia class of plants, and in the natural method ranking under the 40th order, personatæ. The calyx is quinquefid, superior; the berry tetraspermous; the seeds bilocular. There are three species, shrubs of South America.

DURESS, in law, is where a man is kept in prison, or restrained of his liberty, contrary to the order of law; or threatened to be killed, maimed, or beaten: and if such person so in prison, or in fear of such threats, make any specialty or obligation by reason thereof,

such deed is void in law; and in any action brought upon such specialty, the party may plead that it was made by duress, and so he may avoid the action. Cowel.

Every act of contract must be altogether the act of the understanding, which those are incapable of using, who are under restraint and terrors; and therefore the law requires the free assent of the the parties as essential to every contract, and that they be not under any force or violence. 2 Bac. Abr. 155.

DURIO, a genus of the class and order polyadelphia polyandria. The calyx is five-cleft; corola five-petalled; style one; stamina in five bodies; pome five-celled. There is one species, a tree of the East Indies.

DUROIA, in botany, a genus of the monogynia order, belonging to the hexandria class of plants. The calyx above is cylindrical and lobed; the border six-parted; there are no filaments; the fruit a hispid apple. There is one species, a tree of Surinam.

DUTCH-COURT. See CHANCELLOR.

DUTY, in policy and commerce, signifies the impost laid on merchandises, at importation or exportation, commonly called the duties of customs; also the taxes of excise, stamp-duties, &c. See CUSTOMS, EXCISE, & .

There is no task more delicate or difficult to a statesman than the laying on of duties or imposts. Experience teaches us that a very small duty laid on commodities raises the price of them considerably to the consumer, beyond the gross duty. By the fees given to officers; by tradesmen's loss of time in attending upon excisemen, or at custom-houses; by taking away a quarter of our traders' stock for duties; and forcing them to take as great pains on one quarter of their stock laid out in goods, in order to live, as they would on the whole, if duty-free; by tradesmen's profits on the duty, and advances in all the hands that all taxed goods come through to the consumer: as for example, suppose there should be no other tax but that on leather, let us see how many advances that would make on the price of shoes.

The grazier lays (1) on the beast he fats, his advanced price of shoes: he sells to the butcher, who takes (2) his profit on the grazier's advanced price of the beast; and raises (3) on the hide his advanced price of shoes: he sells to the tanner, whose journeymen raise (4) their wages, on account of the advanced price of shoes; the tanner pays (5) the tax of two-pence per pound on the leather; takes (6) his profit on the before-mentioned five advances, and raises (7) his advanced price of shoes on the tanned hide: he sells to the leather-cutter, who takes (8) his profit on the before-mentioned seven advances, and raises (9) on the hide he cuts, his advanced price of shoes: he sells to the shoemaker, whose journeymen raise (10) their wages, on account of their advanced price of shoes; the shoemaker takes (11) his profit on the before-mentioned ten advances, and raises (12) on the shoes he makes the advanced price of the shoes he wears: he sells to the consummer with all these twelve advances, highly magnified beyond the bare duty.

So much for the tax on leather only; but the grazier, butcher, tanner, leather-cutter, and shoemaker, use soap: that soap, like leather, is taxed, and, like that leather-tax, must be raised: but that caused twelve advances on our shoes; place therefore twelve advances more on shoes for the soap-tax. These tradesmen use candles; twelve advances more for the tax on them: and the same for every other tax on necessaries. All which, duly considered, might be computed at above cent. per cent. on the gross produce of the duties; but though the large duties cause some farther advance on all the goods they are laid on, charged with profit upon profit through every hand they pass, yet as they keep not pace with the small duties, and as all calculations appear fair when moderate, let us abate in the advances, and set them down only at 50 per cent.

DUTY, in the military art, is the exercise of those functions that belong to a soldier; with this distinction, that mounting guards and the like, where there is no enemy directly to be engaged, is called duty; but their marching to meet and fight an enemy is called going on service.

DUUMVIRI, in Roman antiquity, a general appellation given to magistrates, commissioners, and officers, where two were joined together in the same functions.

DUUMVIRI CAPITALES were the judges in criminal causes: from their sentence it was lawful to appeal to the people, who only had the power of condemning a citizen to death. The judges were taken from the body of the decuriones; they had great power and authority, were members of the public council, and had two lictors to walk before them.

DUUMVIRI MUNICIPALES, were two magistrates in some cities of the empire, answering to what the consuls were at Rome: they were chosen out of the body of the decuriones; their office lasted commonly five years, upon which account they were frequently termed quinquinales magistratus. Their jurisdiction was of great extent: they had officers walking before them, carrying a small switch in their hands, and some of them assumed the privilege of having lictors, carrying axes and the faces, or bundles of rods, before them.

DUUMVIRI NAVALES, were the commissaries of the fleet, first created at the request of M. Decius, tribune of the people, in the time of the war with the Samnites. The duty of their office consisted in giving orders for the fitting of ships, and giving their commissions to the marine officers, &c.

DUUMVIRI SACRORUM were magistrates created by Tarquinius Superbus, for the performance of the sacrifice, and keeping of the sybil's books. They were chosen from among the patricians, and held their office for life: they were exempted from serving in the wars, and from the offices imposed on the other citizens, and without them the oracles of the sybil could not be consulted.

DWARF, in general, an appellation given to things greatly inferior in size to that which is usual in their several kinds; thus there are dwarfs of the human species, dwarf dogs, dwarf trees, &c.

Dwarf fruit-trees may be propagated by grafting them on a quince-stock, about six inches above the ground; and when the bud is shot so far as to have four eyes, it must be stopped, to give rise to lateral branches; for which purpose the uppermost eye should always be left outwards. Apple, pear, plumb, and cherry-trees are

thus formed into dwarfs; but the summer and autumn pears are found to succeed best.

As to the planting of dwarf trees, they should be set at 25 feet square distance, and the ground between sown or planted for kitchen use while the trees are young, only keeping at some distance from their roots: stakes also should be fixed all round them, to which the branches may be nailed with list, and trimmed in an horizontal direction, and prevented from crossing one another.

DYE, in architecture, any square body, as the trunk, or notched part, of a pedestal. See ARCHITECTURE.

DYE is also used for a cube of stone placed under the feet of a statue, and over its pedestal, to raise it, and show it the more.

DYEING. *Principles of dyeing.*—The substances commonly employed for clothing may be reduced to four; namely wool, silk, cotton, and linen.

Permanent alterations in the colour of cloth can only be induced two ways; either by producing a chemical change in the cloth, or by covering its fibres with some substances which possesses the wished-for colour. Recourse can seldom or never be had to the first method, because it is hardly possible to produce a chemical change in the fibres of cloth, without spoiling its texture, and rendering it useless. The dyer, therefore, when he wishes to give a new colour to cloth, has always recourse to the second method.

The substances employed for this purpose are called colouring matters, or dye-stuffs. They are for the most part extracted from animal and vegetable substances, and have usually the colour which they are to give to the cloth.

Since the particles of colouring matter with which cloth, when dyed, is covered, are transparent, it follows, that all the light reflected from dyed cloth must be reflected, not by the dye-stuff itself, but by the fibres of the cloth below the dye stuff. The colour therefore does not depend upon the dye alone, but also upon the previous colour of the cloth. If the cloth is black, it is clear that we cannot dye it any other colour whatever; because as no light in that case is reflected, none can be transmitted, whatever dye-stuff we employ. If the cloth was red, or blue, or yellow, we could not dye it any colour except black; because, as only red, or blue, or yellow rays were reflected, no other could be transmitted. Hence the importance of a fine white colour, when cloth is to receive bright dyes. It then reflects all the rays in abundance, and therefore any colour may be given, by covering it with a dye-stuff which transmits only some particular rays.

If the colouring matters were merely spread over the surface of the fibres of cloth by the dyer, the colours produced might be very bright, but they could not be permanent; because the colouring matter would be very soon rubbed off; and would totally disappear whenever the cloth was washed, or even barely exposed to the weather. The colouring matter then, however perfect a colour it possesses, is of no value, unless it also adheres so firmly to the cloth that none of the substances usually applied to cloth, in order to clean it, &c. can displace it. Now this can only happen, when there is a strong affinity between the colouring matter and the cloth, and when they are actually combined together in consequence of that affinity.

Dyeing then is merely a chemical process, and consists in combining a certain colouring matter with fibres of cloth. This process can in no instance be performed, unless the dye-stuff is first reduced to its integrant particles; for the attraction of aggregation between the particles of dye-stuffs, is too great to be overcome by the affinity between them and the cloth, unless they could be brought within much smaller distances than is possible while they both remain in a solid form. It is necessary, therefore, previously to dissolve the colouring matter in some liquid or other, which has a weaker affinity for it than the cloth has. When the cloth is dipped into this solution, the colouring matter, reduced by this contrivance to a liquid state, is brought within the attracting distance; the cloth therefore acts upon it, and from its stronger affinity, takes it from the solvent, and fixes upon itself. By this contrivance too, the equality of the colour is in some measure secured, as every part of the cloth has an opportunity of attracting to itself the proper proportion of colouring particles.

The facility with which cloth imbibes a dye, depends upon two circumstances; namely, the affinity between the cloth and the dye-stuff, and the affinity between the dye-stuff and its solvent. It is directly as the former, and inversely as the latter. It is of importance to preserve a due proportion between these two affinities, as upon that proportion much of the accuracy of dyeing depends. If the affinity between the colouring matter and the cloth is too great, compared with the affinity between the colouring matter and the solvent, the cloth will take the dye too rapidly, and it will be scarcely possible to prevent its colour from being unequal. On the other hand, if the affinity between the colouring matter and the solvent is too great, compared with that between the colouring matter and the cloth, the cloth will either not take the colour at all, or it will take it very slowly and very faintly.

Wool has the strongest affinity for almost all colouring matters, silk the next strongest, cotton a considerably weaker affinity, and linen the weakest affinity of all. In order therefore, to dye cotton or linen, the dye stuff should in many cases be dissolved in a substance for which it has a weaker affinity than for the solvent employed in the dyeing of wool or silk. Thus we may use oxide of iron dissolved in sulphuric acid, in order to dye wool; but for cotton and linen, it is better to dissolve it in acetous acid.

Was it possible to procure a sufficient number of colouring matters, having a strong affinity for cloth, to answer all the purposes of dyeing, that art would be exceedingly simple and easy. But this is by no means the case; if we except indigo, the dyer is scarcely possessed of a dye-stuff which yields of itself a good colour, sufficiently permanent to deserve the name of a dye.

This difficulty, which at first sight appears insurmountable, has been obviated by a very ingenious contrivance. Some substance is employed, which has a strong affinity, both for the cloth and the colouring matter. This substance is previously combined with the cloth, which is then dipped into the solution containing the dye-stuff. The dye-stuff combines with the intermediate

substance, which, being firmly combined with the cloth, secures the permanence of the dye. Substances employed for this purpose are denominated mordants.

The most important part of dyeing, is undoubtedly the proper choice, and the proper application, of mordants; as upon them, the permanency of almost every dye depends. Every thing which has been said respecting the application of colouring matters, applies equally to the application of mordants. They must be previously dissolved in some liquid, which has a weaker affinity for them than the cloth has, to which they are to be applied; and the cloth must be dipped, or even steeped in this solution, in order to saturate itself with the mordant.

Almost the only substances used as mordants, are earths, metallic oxides, tan, and oil.

Of earthy mordants the most important, and most generally used, is alumina. It is used either in the state of common alum, in which it is combined with sulphuric acid, or in that of acetite of alumina.

Alum, when used as a mordant, is dissolved in water, and very frequently a quantity of tartar is dissolved along with it. Into this solution the cloth is put, and kept in it till it has absorbed as much alumina as is necessary. It is then taken out, and for the most part washed and dried. It is now a good deal heavier than it was before, owing to the alumina which has combined with it. The tartar serves two purposes; the potass which it contains, combines with the sulphuric acid of the alum, and thus prevents that very corrosive substance from injuring the texture of the cloth, which otherwise might happen: the tartareous acid, on the other hand, combines with part of the alumina, and forms a tartrite of alumina, which is more easily decomposed by the cloth than alum.

Acetite of alumina has been but lately introduced into dyeing. This mordant is now prepared by pouring acetite of lead into a solution of alum; a double decomposition takes place, the sulphureous acid combines with the lead, and the compound precipitates, in the form of an insoluble powder, while the alumina combines with the acetous acid, and remains dissolved in the liquid. This mordant is employed for cotton and linen, which have a weaker affinity than wool for alumina. It answers much better than alum; the cloth is much easier saturated with alumina, and takes in consequence, both a richer and more permanent colour.

Besides alumina, lime is sometimes used as a mordant. Cloth has a strong affinity enough for it; but, in general, it does not answer so well, as it does not give so good a colour. When used, it is either in the state of lime-water, or of sulphate of lime dissolved in water.

Almost all the metallic oxides have an affinity for cloth, but only two of them are extensively used as mordants, namely, the oxides of tin, and of iron.

The oxide of tin was first introduced into dyeing by Kuster, a German chemist, who brought the secret to London in 1543. This period forms an æra in the history of dyeing. The oxide of tin has enabled the moderns greatly to surpass the ancients in the fineness of their colours; by means of it alone, scarlet, the brightest of all colours, is produced.

Tin, as Proust has proved, is capable of two degrees of oxydation. The first oxide is composed of 0.70 parts of tin, and 0.30 of oxygen; the second, or white oxide, of 0.60 parts of tin, and 0.40 of oxygen. The first oxide absorbs oxygen with very great facility, even from the air, and is rapidly converted into white oxide. This fact makes it certain, that it is the white oxide of tin alone, which is the real mordant; even if the other oxide was applied to cloth, as it probably often is, it must soon be converted into white oxide, by absorbing oxygen from the atmosphere.

Tin is used as a mordant in three states: dissolved in nitro-muriatic acid, in acetous acid, and in a mixture of sulphuric and muriatic acids. Nitro-muriate of tin is the common mordant employed by dyers. They prepare it by dissolving tin and diluted nitric acid, to which a certain proportion of muriate of soda (common salt), or of ammonia (sal ammoniac), is added. Part of the nitric acid decomposes these salts, combines with their base, and sets the muriatic acid at liberty. It was prepared at first with nitric acid alone, but that mode was very defective, because the nitric acid very readily converts tin to white oxide, and then is incapable of dissolving it; the consequence of which was, the precipitation of the whole of the tin. To remedy this defect, common salt, or sal ammoniac, was very soon added; muriatic acid having the property of dissolving white oxide of tin very readily. A considerable saving of nitric acid might be obtained, by employing as much sulphuric acid as is just sufficient to saturate the base of the common salt, or sal ammoniac, employed.

When the nitro-muriate of tin is to be used as a mordant, it is dissolved in a large quantity of water, and the cloth is dipped in the solution, and allowed to remain till sufficiently saturated. It is then taken out, and washed and dried. Tartar is usually dissolved in the water along with the nitro-muriate. The consequence of this is a double decomposition: the nitro-muriatic acid combines with the potass of the tartar, while the tartareous acid dissolves the oxide of tin. When tartar is used, therefore, in any considerable quantity, the mordant is not a nitro-muriate, but a tartrite of tin.

Iron, like tin, is capable of two degrees of oxydation; but the green oxide absorbs oxygen so readily from the atmosphere, that it is very soon converted into the red oxide. It is only this last oxide which is really used as a mordant in dyeing. The green oxide is, indeed, sometimes applied to cloth; but it very soon absorbs oxygen, and is converted into the red oxide. This oxide has a very strong affinity for all kinds of cloth. The permanency of the iron-spots on linen and cotton is a sufficient proof of this. As a mordant, it is used in two states; in that of sulphate of iron (copperas), and acetite of iron. The first is commonly used for wool. The salt is dissolved in water, and the cloth dipped in it. It may be used also for cotton, but in most cases acetite of iron is preferred. It is prepared by dissolving iron, or its oxide, in vinegar, sour beer, &c. and the longer it is kept, the more it is preferred. The reason is, that this mordant succeeds best when the iron is in the state of red oxide. It would be better then to oxidate the iron, or convert it into rust, before using it; which might be easily done, by keeping it for some time in a moist place, and sprinkling it occasionally with water.

Tin has a very strong affinity for cloth, and for several colouring matters; it is therefore very frequently

employed as a mordant. An infusion of nut-galls, or of sumach, or any other substance containing tan, is made in water, and the cloth is dipped in this infusion, and allowed to remain till it has absorbed a sufficient quantity of tan. Silk is capable of absorbing a very great proportion of tan, and by that means acquires a great increase of weight. Manufactures sometimes employ this method of increasing the weight of silk.

Tan is often employed also, along with other mordants, in order to produce a compound mordant. Oil is also used for the same purpose, in the dyeing of cotton and linen. The mordants with which tan most frequently is combined, are alumina, and oxide of iron.

Besides these mordants, there are several other substances frequently used as auxiliaries, either to facilitate the combination of the mordant with the cloth, or to alter the shade of colour; the chief of these are, tartar, acetite of lead, common salt, sal ammoniac, sulphate or acetite of copper, &c.

Mordants not only render the dye permanent, but have also considerable influence on the colour produced. The same colouring matter produces very different dyes, according as the mordant is changed. Suppose, for instance, that the colouring matter is cochineal; if we use the aluminous mordant, the cloth will acquire a crimson colour; but the oxide of iron produces with it a black.

In dyeing then, it is not only necessary to procure a mordant which has a sufficiently strong affinity for the colouring matter and the cloth, and a colouring matter which possesses the wished-for colour in perfection, but we must procure a mordant and a colouring matter of such a nature, that when combined together, they shall possess the wished-for colour in perfection. It is evident too, that a great variety of colours may be produced with a single dye-stuff, provided we can change the mordant sufficiently.

The colouring matter with which the cloth is dyed, does not cover every portion of its surface; its particles attach themselves to the cloth at certain distances from each other; for cloth may be died different shades of the same colour, lighter or darker, merely by varying the quantity of colouring matter. With a small quantity, the shade is light; and it becomes deeper as the quantity increases. Now this would be impossible, if the dye-stuff covered the whole of the cloth.

That the particles of colouring matter, even when the shade is deep, are at some distance, is evident from this well-known fact, that cloth may be dyed two colours at the same time. All those colours to which the dyers give the name of compound, are in fact two different colours applied to the cloth at once. Thus cloth gets a green colour, by being first dyed blue and then yellow.

The colours denominated by dyers simple, because they are the foundation of all their other processes, are four: namely, first, blue: second, yellow; third, red; fourth, black. To these they usually add a fifth, under the name of root or brown colour.

Of dyeing blue.—The only colouring matters employed in dyeing blue, are woad and indigo.

Woad is a plant cultivated in England, and even growing wild in some parts of it.

Indigo is a blue powder, extracted from a species of plant which is cultivated for that purpose in the East and West Indies. These plants contain a peculiar green pollen, which in that state is soluble in water. This pollen has a strong affinity for oxygen, which it attracts greedily from the atmosphere; in consequence of which it assumes a blue colour, and becomes insoluble in water.

Indigo has a very strong affinity for wool, silk, cotton, and linen. Every kind of cloth, therefore, may be dyed with it, without the assistance of any mordant whatever. The colour thus induced is very permanent; because the indigo is already saturated with oxygen, and because it is not liable to be decomposed by those substances, to the action of which the cloth is exposed. But it can only be applied to cloth in a state of solution; and the only solvent known being sulphuric acid, it would seem at first sight, that the sulphuric acid solution is the only state in which indigo can be employed as a dye.

The sulphate of indigo is indeed often used to dye wool and silk blue; but it can scarcely be applied to cotton and linen, because the affinity of these substances for indigo is not great enough to enable them readily to decompose the sulphate. The colour given by sulphate of indigo is exceedingly beautiful; it is known by the name of Saxon blue.

One part of indigo is to be dissolved in four parts of concentrated sulphuric acid; to the solution one part of dry carbonate of potass is to be added, and then it is to be diluted with eight times its weight of water. The cloth must be boiled for an hour in a solution, containing five parts of alum, and three of tartar, for every 32 parts of cloth. It is then to be thrown into a water-bath, containing a greater or smaller proportion of the diluted sulphate of indigo, according to the shade which the cloth is intended to receive. In this bath it must be boiled till it has acquired the wished-for colour.

The alum and tartar are not intended to act as mordants, but to facilitate the decomposition of the sulphate of indigo. The alkali added to the sulphate, answers the same purpose. These substances also, by saturating part of the sulphuric acid, serve in some measure to prevent the texture of the cloth from being injured by the action of the acid, which is very apt to happen in this process.

But sulphate of indigo is by no means the only solution of that pigment employed in dyeing. By far the most common method is, to deprive indigo of the oxygen, to which it owes its blue colour, and thus to reduce it to the state of green pollen; and then to dissolve it in water by means of alkalis, or alkaline earths, which in that state act upon it very readily.

Two different methods are employed for this purpose. The first of these methods is, to mix with indigo a solution of some substance which has a stronger affinity for oxygen than the green basis of indigo; green oxide, for instance, and different metallic sulphurets. If therefore indigo, lime, and green sulphate of iron, are mixed together in water, the indigo gradually loses its blue colour, becomes green, and is dissolved; while the green oxide of iron is converted into the red oxide. The manner in which these changes take place is obvious; part of the lime decomposes the sulphate of iron; the green

oxide, the instant that it is set at liberty, attracts oxygen from the indigo, decomposes it, and reduces it to the state of green pollen. This green pollen is immediately dissolved by the action of the rest of the lime.

The second method is, to mix the indigo in water with certain vegetable substances, which readily undergo fermentation. During this fermentation, the indigo is deprived of its oxygen, and dissolved by means of quick-lime or alkali, which is added to the solution. The first of these methods is usually followed in dyeing cotton and linen; the second, in dyeing wool and silk.

In the dyeing of wool, woad and bran are commonly employed as vegetable ferments, and lime as the solvent of the green base of the indigo. Woad itself contains a colouring matter precisely similar to indigo; and by following the common process, indigo may be extracted from it. In the usual state of woad, when purchased by the dyer, the indigo which it contains is probably not far from the state of the green pollen. Its quantity in woad is but small, and it is mixed with a great proportion of other vegetable matter.

When the cloth is first taken out of the vat, it is of a green colour; but it soon becomes blue, by attracting oxygen from the air. It ought to be carefully washed, to carry off the uncombined particles. This solution of indigo is liable to two inconveniences: first, it is apt sometimes to run too fast into the putrid fermentation; this may be known by the putrid vapours which it exhales, and by the disappearing of the green colour. In this state it would soon destroy the indigo altogether. The inconvenience is remedied by adding more lime, which has the property of moderating the putrescent tendency. Secondly, sometimes the fermentation goes on too languidly. This defect is remedied by adding more bran or woad, in order to diminish the proportion of quick-lime.

Silk is dyed light-blue by a ferment of six parts of bran, six of indigo, six of potass, and one of madder. To dye it of a dark blue, it must previously receive what is called a ground-colour; a red dye-stuff, called archil, is used for this purpose.

Cotton and linen are dyed blue by a solution of one part of indigo, one part of green sulphate of iron, and two parts of quick-lime.

Of dyeing yellow.—The principal colouring matters for dyeing yellow are weld, fustic, and quercitron bark.

Weld is a plant which grows commonly in England, reseda luteola.

Fustic is the wood of a large tree which grows in the West Indies, morus tinctoria.

Quercitron is a tree growing in North America, the bark of which contains colouring matter.

Yellow colouring matters have too weak an affinity for cloth, to produce permanent colours without the use of mordants. Cloth, therefore, before it is dyed yellow, is always prepared by combining some mordant or other with it. The mordant most commonly employed for this purpose, is alumina. Oxide of tin is sometimes used when very fine yellows are wanting. Tan is often employed as a subsidiary to alumina, and in order to fix it more copiously on cotton and linen. Tartar is also used as an auxiliary, to brighten the colour; and muriate of soda, sulphate of lime, and even sulphate of iron, in order to render the shade deeper.

The yellow dyed by means of fustic is more permanent, but not so beautiful as that given by weld, or quercitron. As it is permanent, and not much injured by acids, it is often used in dyeing compound colours, where a yellow is required. The mordant is alumina. When the mordant is oxide of iron, fustic dyes a good permanent drab colour.

Weld and quercitron bark yield nearly the same kind of colour; but as the bark yields colouring matter in much greater abundance, it is much more convenient, and upon the whole, cheaper than weld. It is probable, therefore, that it will gradually supersede the use of that plant. The method of using each of these dye-stuffs is nearly the same.

Wool may be dyed yellow by the following process: Let it be boiled for an hour or more with about $\frac{1}{8}$th of its weight of alum, dissolved in a sufficient quantity of water. It is then to be plunged, without being rinsed, into a bath of warm water, containing in it as much quercitron bark, as equals the weight of the alum employed as a mordant. The cloth is to be turned through the boiling liquid, till it has acquired the intended colour. Then a quantity of clean powdered chalk, equal to the hundredth part of the weight of the cloth, is to be stirred in, and the operation of dyeing continued for eight or ten minutes longer. By this method a pretty deep and lively yellow may be given, fully as permanent as weld yellow.

For very bright orange or golden yellow, it is necessary to have recourse to the oxide of tin as a mordant.

For producing bright golden yellows, some alum must be added along with the tin.

In order to give the yellow that delicate green shade so much admired for certain purposes, tartar must be added in different proportions, according to the shade.

By adding a small proportion of cochineal, the colour may be raised to a fine orange, or even an aurora.

Silk may be dyed different shades of yellow, either by weld or quercitron bark, but the last is the cheapest of the two. The proportion should be from one to two parts of bark to twelve parts of silk, according to the shade. The bark, tied up in a bag, should be put into the dyeing vessel, while the water which it contains is cold; and when it has acquired the heat of about 100°, the silk, having been previously alumed, should be dipped in, and continued till it assumes the wished-for colour. When the shade is required to be deep, a little chalk or pearl-ash should be added towards the end of the operation.

The best method of dyeing cotton and linen yellow, is as follows:

The mordant should be acetite of alumina, prepared by dissolving one part of acetite of lead, and three parts of alum, in a sufficient quantity of water. This solution should be heated to the temperature of 100°: the cloth should be soaked in it for two hours, then wrung out and dried. The soaking may be repeated, and the cloth again dried as before. It is then to be barely wetted with lime-water, and afterwards dried. The soaking in the acetite of alumina may be again repeated; and if the shade of yellow is required to be very bright and durable, the alternate wetting with lime-water and soaking

in the mordant may be repeated three or four times. By this contrivance, a sufficient quantity of alumina is combined with the cloth, and the combination is rendered more permanent by the addition of some lime. The dyeing-bath is prepared by putting 12 or 18 parts of quercitron bark (according to the depth of the shade required), tied up in a bag, into a sufficient quantity of cold water. Into this bath the cloth is to be put, and turned round in it for an hour, while its temperature is gradually raised to about 120°. It is then to be brought to a boiling heat, and the cloth allowed to remain in it after that only a few minutes. If it is kept long at a boiling heat, the yellow acquires a shade of brown.

Of dyeing red.—The colouring matters employed for dyeing red, are kermes, cochineal, archil, madder, carthamus, and Brazil-wood.

Kermes is a species of insect, affording a red colour by solution in water; but it is not so beautiful as cochineal, which is likewise an insect common in America (see both under Coccus). The decoction of cochineal is a very beautiful crimson-colour. Alum brightens the colour of the decoction, and occasions a crimson precipitate. Muriate of tin gives a copious fine red precipitate.

Archil is a paste formed of a species of lichen pounded, and kept moist for some time with stale urine.

Madder is the root of a well-known plant, rubia tinctorum.

Carthamus is the flower of a plant (carthamus tinctorius), cultivated in Spain and the Levant. It contains two colouring matters: a yellow, which is soluble in water; and a red, insoluble in water, but soluble in alkaline carbonates. The red colouring matter of carthamus, extracted by carbonate of soda, and precipitated by lemon-juice, constitutes the rouge employed by ladies as a paint. It is afterwards ground with a certain quantity of talc. The fineness of the talc, and the proportion of it mixed with the carthamus, occasion the difference between the cheaper and dearer kinds of rouge.

Brazil-wood is the wood of a tree growing in America and the West Indies (See Cæsalpinia). Its decoction is a fine red colour.

None of the red colouring matters has so strong an affinity for cloth as to produce a permanent red, without the assistance of mordants. The mordants employed are alumina and oxide of tin; oil, and tan, in certain processes, are also used; and tartar, and muriate of soda, are frequently called in as auxiliaries.

Coarse woollen stuffs are dyed red with madder or archil; but fine cloth is almost exclusively dyed with cochineal, though the colour which it receives from kermes is much more durable. Brazil-wood is scarcely used, except as an auxiliary, because the colour which it imparts to wool is not permanent.

Wool is dyed crimson, by first impregnating it with alumina, by means of an alum bath, and then boiling it in a decoction of cochineal, till it has acquired the wished-for colour. The crimson will be finer if the tin mordant is substituted for alum; indeed, it is usual with dyers to add a little nitro-muriate of tin, when they want fine crimsons. The addition of archil and potass to the cochineal, both renders the crimson darker, and gives it more bloom; but the bloom very soon vanishes. For paler crimsons, one-half of the cochineal is withdrawn, and madder substituted in its place.

Wool may be dyed scarlet, the most splendid of all colours, by first boiling it in a solution of murio-sulphate of tin, then dyeing it pale yellow with quercitron bark, and afterwards crimson with cochineal; for scarlet is a compound colour consisting of crimson mixed with a little yellow.

Silk is usually dyed red with cochineal or carthamus, and sometimes with Brazil-wood. Kermes does not answer for silk; madder is scarcely ever used for that purpose, because it does not yield a colour bright enough. Archil is employed to give silk a bloom; but it is scarcely used by itself, unless when the colour wanted is lilac.

Silk may be dyed crimson by steeping it in a solution of alum, and then dyeing it in the usual way in a cochineal bath.

The colours known by the names of poppy, cherry, rose, and flesh-colour, are given to silk by means of carthamus. The process consists merely in keeping the silk as long as it extracts any colour, in an alkaline solution of carthamus, into which as much lemon-juice as gives it a fine cherry colour has been poured.

Silk cannot be dyed a full scarlet; but a colour approaching to scarlet may be given it, by first impregnating the stuff with murio-sulphate of tin, and afterwards dyeing it in a bath, composed of four parts of cochineal, and four parts of quercitron bark. To give the colour more body, both the mordant and the dye may be repeated. A colour approaching scarlet may be also given to silk, by first dyeing it in crimson, then dyeing it with carthamus, and lastly, yellow without heat. Cotton and linen are dyed red with madder. The process was borrowed from the East; hence the colour is often called Adrianople or Turkey red. The cloth is first impregnated with oil, then with galls, and lastly with alum. It is then boiled for an hour in a decoction of madder, which is commonly mixed with a quantity of blood. After the cloth is dyed, it is plunged into a soda ley, in order to brighten the colour. The red given by this process, is very permanent, and when properly conducted, it is exceedingly beautiful. The whole difficulty consists in the application of the mordant, which is by far the most complicated employed in the whole art of dyeing.

Cotton may be dyed scarlet, by means of murio-sulphate of tin, cochineal, and quercitron bark, used as for silk, but the colour is too fading to be of any value.

Of dyeing black.—The substances employed to give a black colour to cloth are, red oxide of iron, and tan. These two substances have a strong affinity for each other; and when combined, assume a deep black colour, not liable to be destroyed by the action of air or light.

Logwood is usually employed as an auxiliary, because it communicates lustre, and adds considerably to the fullness of the black. It is the wood of a tree (See Hæmatoxylon) which is a native of several of the West India islands, and of that port of Mexico which surrounds the Bay of Honduras. It yields its colouring matter to water. The decoction is at first a fine red, bordering on violet; but if left to itself, it gradually assumes a black colour. Acids give it a deep red colour;

alkalis a deep violet, inclining to brown; sulphate of iron renders it as black as ink, and occasions a precipitate of the same colour.

Cloth, before it receives a black colour, is usually dyed blue: this renders the colour much fuller and finer than it would otherwise be. If the cloth is coarse, the blue dye may be too expensive; in that case, a brown colour is given, by means of walnut-peels.

Wool is dyed black by the following process. It is boiled for two hours in a decoction of nut-galls, and afterwards kept for two hours more in a bath composed of logwood and sulphate of iron, kept during the whole time at a scalding heat, but not boiled. During the operation, it must be frequently exposed to the air; because the green oxide of iron, of which the sulphate is composed, must be converted into red oxide by absorbing oxygen, before the cloth can acquire a proper colour. The common proportions are five parts of galls, five of sulphate of iron, and thirty of logwood, for every hundred of cloth. A little acetite of copper is commonly added to the sulphate of iron, because it is thought to improve the colour.

Silk is dyed nearly in the same manner. It is capable of combining with a great deal of tan; the quantity given is varied at the pleasure of the artist, by allowing the silk to remain a longer or shorter time in the decoction.

It is by no means so easy to give a full black to linen and cotton. The cloth, previously dyed blue, is steeped for 24 hours in a decoction of nut-galls. A bath is prepared, containing an acetite of iron, formed by saturating acetous acid with brown oxyd of iron: into this bath the cloth is put in small quantities at a time, wrought with the hand for a quarter of an hour, then wrung out, and aired again; wrought in a fresh quantity of the bath, and afterwards aired. These alternate processes are repeated, till the colour wanted is given: a decoction of alder bark is usually mixed with the liquor containing the nut-galls.

Of dyeing brown.—Brown, or fawn colour, though in fact a compound, is usually ranked among the simple colours, because it is applied to cloth by a simple process. Various substances are used for brown dyes.

Walnut-peels, or the green covering of the walnut, when first separated are white internally, but soon assume a brown, or even a black colour, on exposure to the air. They readily yield their colouring matter to water. They are usually kept in large casks, covered with water, for above a year before they are used. To dye wool brown with them, nothing more is necessary, than to steep the cloth in a decoction of them till it has acquired the wished-for colour. The depth of the shade is proportional to the strength of the decoction. The root of the walnut-tree contains the same colouring matter, but in smaller quantity. The bark of the birch also, and many other trees, may be used for the same purpose. It is very probable that the brown colouring matter is in these vegetable substances combined with tan. This is certainly the case in sumach, which is often employed to produce a brown. This combination explains the reason why no mordant is necessary; the tan has a strong affinity for cloth, and the colouring matter for the tan. The dye-stuff, and the mordant, are already, in fact, combined together.

Of dyeing compound colours.—Compound colours are produced by mixing together two simple ones; or, which is the same thing, by dyeing cloth first one simple colour, and then another. These colours vary to infinity, according to the proportions of the ingredients employed. They may be arranged under the following classes.

Mixtures of, 1. Blue and yellow; 2. Blue and red; 3. Yellow and red; 4. Black and other colours.

Mixture of blue and yellow.—This forms green; which is distinguished by dyers into a variety of shades, according to the depth of the shade, or the prevalence of either of the component parts. Thus we have sea-green, grass-green, pea-green, &c.

Wool, silk, and linen, are usually dyed green by giving them first a blue colour, and afterwards dyeing them yellow; because, when the yellow is first given, several inconveniences follow: the yellow partly separates again in the blue vat, and communicates a green colour to it, and thus renders it useless for every other purpose, except dyeing green. Any of the usual processes for dyeing blue and yellow may be followed, taking care to proportion the depth of the shades to that of the green required. When sulphate of indigo is employed, it is usual to mix all the ingredients together, and to dye the cloth at once; this produces what is known by the name of Saxon or English green.

Mixtures of blue and red.—These form different shades of violet, purple, and lilac. Wool is generally first dyed blue, and afterwards scarlet, in the usual manner. By means of cochineal mixed with sulphate of indigo, the process may be performed at once. Silk is first dyed crimson, by means of cochineal, and then dipped into the indigo vat. Cotton and linen are first dyed blue, then galled, and soaked in a decoction of logwood; but a more permanent colour is given by means of oxide of iron.

Mixtures of yellow and red.—These produce orange. When blue is combined with red and yellow on cloth, the resulting colour is olive. Wool may be dyed orange, by first dyeing it scarlet, and then yellow. When it is dyed first with madder, the result is cinnamon-colour.

Silk is dyed orange by means of carthamus; a cinnamon colour by logwood, Brazil-wood, and fustic mixed together.

Cotton and linen receive a cinnamon-colour by means of weld and madder; and an olive-colour, by being passed through a blue, yellow, and then a madder-bath.

Mixtures of black with other colours.—These constitute greys, drabs, and browns. If cloth is previously combined with brown oxide of iron, and afterwards dyed yellow with quercitron bark, the result will be a drab of different shades, according to the proportion of mordant employed. When the proportion is small, the colour inclines to olive or yellow; on the contrary, the drab may be deepened or saddened, as the dyers term it, by mixing a little sumach with the bark. See CALICO-PRINTING.

DYERS. By stat. 3 & 4 Ed. VI. c. 2, no dyer may dye any cloth with orchel, or with brazil, to make a false colour in cloth, wool, &c. on penalty of 20*s*. By stat. 23 Eliz. c. 9, dyers are to fix a seal of lead to

cloths, with the letter M, to show that they are well maddered, &c. or forfeit 3*s.* 4*d.* per yard. By stat. 23 Geo. III. c. 15, several penalties are inflicted on dyers who dye any cloths deceitfully, and not woaded throughout with indigo and madder. Dying blue with logwood, to forfeit 20*l.* Dyers in London are subject to the inspection of the dyers' company, who appoint searches. In other places, these are appointed by the justices, and opposing the searchers incurs a penalty of 10*l.*

DYNASTY, among ancient historians, signifies a race or succession of kings of the same line or family: such were the dynasties of Egypt. The Egyptians reckon thirty dynasties, within the space of 36525 years; but the generality of chronologers look upon them as fabulous. And it is very certain, that these dynasties are not continually successive, but collateral.

DYSENTERY. See MEDICINE.

DYSOREXY, among physicians, denotes a want of appetite, proceeding from a weak stomach.

DYSPEPSY, a difficulty of digestion, for which physicians prescribe bitters. See MEDICINE.

DYSPNŒA, a difficulty of breathing, usually called asthma. See MEDICINE.

DYSURY, in medicine, a difficulty of making urine, attended with a sensation of heat and pain. It is distinguished from a strangury, as, in the last, the urine is voided by only a drop, as it were, at a time, but however with pain; and from an ischury, as in this disorder there is an almost total suppression of urine. See MEDICINE.

DYTISCUS, THE WATER-BEETLE, in zoology, a genus of insects of the order of coleoptera; the antennæ of which are slender and setaceous, and the hind feet are hairy, and formed for swimming. There are 23 species, distinguished by their antennæ, the various colours of the elytra, &c. The larvæ of the dytiscus are often met with in water. They are oblong, and have six scaly feet. The body consists of eleven segments. The head is large, with four filiform antennæ, and a strong pair of jaws. The last segments of the body have rows of hairs on the sides; and the abdomen is terminated by two spines charged with the like hairs, forming a kind of plumes. These larvæ are frequently of a greenish variegated brown: they are lively, active, and extremely voracious: they devour and feed upon other water-insects, and often tear and destroy each other. The perfect insect is little inferior to its larvæ in voraciousness, but it can only exercise its cruelty on the larvæ; the perfect insects, like himself, being sheltered by the kind of scaly cuirass with which they are armed. This creature must be touched cautiously; for, besides its power of giving a severe gripe with its jaws, it has moreover under the thorax, another weapon, a long sharp spine, which it will drive into one's fingers by the effort it makes to move backwards. The eggs of the dytisci are rather large, and are by them inclosed in a kind of silky duskish cod, of a strong and thick texture, in form round, and terminated by a long appendix or slender tail, of the same substance. These cods are often found in the water, and from them are brought forth the eggs and larvæ of the dytisci. The strength of these cods probably serves the insect to defend their eggs from the voraciousness of several other aquatic insects, and even from that of their fellow-dytisci, who would not spare them.

Many species of the perfect insect are common in stagnated waters, which they quit in the evening to fly about. They swim with incredible agility, making use of their hinder legs after the fashion of oars. The elytra of the females are, in general, furrowed, and those of the male plain. When they first arrive at their perfect state, their elytra are almost transparent, and in many species of a beautiful dun colour, mingled with shades of a greenish brown. The best method of catching them is with a hand-net or sieve; for they are so nimble, and exercise their defensive weapons so often, and with such painful success to those who endeavour to catch them, that they are very often obliged to let them escape; the easiest way to kill them is, to let them fall into boiling-hot water, which instantly destroys them. See Plate L. Nat. Hist. fig. 175.

E.

E, the fifth letter of the alphabet as a numeral, stands for 250. In music, it denotes the tone *e-la-mi*. In the calandar, it is the fifth of the dominical letters. And in sea-charts, it distinguishes all the easterly points: thus, E. alone denotes east, E. by S. and E. by N. east by south and east by north.

EAGLE, in ornithology. See FALCO.

EAGLE, in heraldry, is accounted one of the most noble bearings. The reason why eagles are generally borne with their wings and tail expanded is, because this posture is best fitted to fill up the escutcheon. However, there are eagles borne in other postures, though not so common; all which will be explained under their respective articles. The arms of the emperor of Germany are, or, a spread eagle with two heads, sable; diademed, langued, beaked, and membered, gules. Some authors express the two heads by the term displayed. The kingdom of Poland bore, gules, an eagle, argent; crowned and membered, or.

EAGLE-STONE. See ÆTITE.

EAGLE, *Black*, an order of knighthood, instituted by the elector of Brandenburgh, in 1701, on his being crowned king of Prussia. The knights of this order wear an orange-coloured ribband, suspending a black eagle.

EAGLE, *White*, a like order in Poland, instituted in 1325, by Uladislaus V. on occasion of the marriage of his son Casimir to the daughter of the great-duke of Lithuania. The knights of this order wore a chain of gold, suspending a silver eagle, crowned.

EAR, *auris*, in anatomy, the organ of hearing. See ANATOMY.

EARING, in the sea-language, is that part of the bolt-rope which, at the four corners of the sail, is left

open, in the shape of a ring. The two uppermost parts are put over the ends of the yard-arms, and so the sail is made fast to the yard; and into the lowermost earings, the sheets and tacks are seized or bent at the clew.

EARL, a British title of nobility, next below a marquis, and above a viscount. Earls were anciently called comites, because they were wont *comitari regem*, to wait upon the king, for council and advice. The Germans call them *graves*, as landgrave, margrave, palsgrave, rheingrave; the Saxons caldormen, unless that title might be more properly applied to our dukes; the Danes, eorlas; and the English, earls. The title originally died with the man. William the Conqueror first made it hereditary, giving it in fee to his nobles, and allotting them for the support of their state the third penny out of the sheriff's court, issuing out of all pleas of the shire; whence they had their title. But now the matter is quite otherwise; for formerly *comes* and *comitatus* were correlatives, and there was no comes or earl but had a county or shire for his earldom; of later years, the number of earls increasing, and no more counties being left, divers have made choice of some eminent part of a county, as Lindsey, Holland, Cleveland, &c.; some of a lesser part, as Stafford, &c.; others have chosen for their title some eminent town, as Marlborough, Exeter, Bristol, &c.; and some have taken for their title the name of a small village, or their own seat or park, as Godolphin, Clarendon, &c.; and others have the title added to the family name, as earl Rivers, earl Stanhope, &c. An earl is created by cincture of sword, mantle of state put upon him by the king himself, a cap and a coronet put upon his head, and a charter in his hand.

EARL *marshal of England*, is a great officer, who had anciently several courts under his jurisdiction, as the court of chivalry, and the court of honour. Under him is also the heralds' office, or college of arms. He has some pre-eminence in the court of marshalsea, where he may sit in judgment against those who offend within the verge of the king's court. This office is of great antiquity in England, and anciently of greater power than now; and has been for several ages hereditary in the most noble family of Howard.

EARNEST, is the money advanced to bind the parties to the performance of a verbal agreement. The person who gives it, is in strictness obliged to abide by his bargain; and in case he declines, is not discharged upon forfeiting his earnest, but may be sued for the whole money stipulated, and damages; and by the statute of frauds 29 H. II. c. 3. no contract for sale of goods to the value of 10*l*. or more is to be valid, unless such earnest is given.

EARTH, in astronomy and geography, one of the primary planets, being this terraqueous globe which we inhabit.

EARTH, FIGURE OF, was accounted by some of the ancients to be like that of an oblong cylinder; by others, of the form of a drum; and by others to be flat. The moderns demonstrate it to be nearly sperical, from the following among other considerations. 1. All the appearances of the heavens, both at land and at sea, are the same as they would be if the earth was a globe. 2. In eclipses of the moon, which are caused by the shadow of the earth falling upon the moon, this shadow is always circular, and a body can be no other than a globe, which, in all situations, casts a circular shadow. 3. Several navigators have sailed quite round the globe, steering their course directly south and west till they came to the Magellanic sea, and thence to the north and west till they returned to their port from the east: and all the phænomena, which should naturally arise from the earth's rotundity, happened to them. Besides, their method of sailing was also founded upon this hypothesis, which could never have succeeded, if the earth had been of any other figure. It is true, the surface of the earth is not an exact geometrical globe, but then the inequalities are so inconsiderable, that the highest mountain bears no greater proportion to the bulk of the earth, than a grain of dust does to a common globe. The figure of the earth was formerly considered, by mathematicians and geographers, as perfectly spherical, excepting the small inequalities on its surface, of mountains and valleys; till an accident engaged the attention of sir Isaac Newton and Mr. Huygens, who demonstrated from the laws of hydrostatics, and the revolution of the earth about its axis, that its figure was not a true sphere, but an oblate spheroid flatted towards the poles. Monsieur Richer, when at the island of Cayenne, about five degrees distant from the equator, found that his clock which, at Paris, kept true time, here lost two minutes and twenty-eight seconds every day. Now, though heat will lengthen pendulums, and consequently retard their motion, it is certain the heats of Cayenne were not sufficient to solve this phænomenon, which can flow only from a diminution in the pressure of gravity. For, as the earth revolves about its axis, all its parts will endeavour to recede from the axis of motion, and the equatorial parts where the motion is quickest will tend less towards the centre than the rest; their endeavour to fly off from the axis about which they revolve, taking off part of their tendency that way; so that those parts will become lighter than such as are nearer the poles. The polar parts, therefore, will press in towards the centre, and raise the equatorial parts, till the quantity of matter in the latter is so far increased as to compensate for its lightness, and an equilibrium is restored; on which account, the form which the earth assumes will be that of an oblate spheroid, whose shorter axis passes through the poles. By virtue only of the rotation of the earth about its axis, the weight of bodies at the equator is less than at the poles, in the proportion of 288 to 289. Hence arises, as before observed, a spheroidical form of the earth; and from that spheroidical form arises another diminution of gravity at the equator, by which if the earth was homogeneous throughout, bodies at the equator would lose one pound in 1121; and so on both accounts taken together, the gravity of bodies at the poles would be to the same at the equator as 230 to 229. Whence, if we suppose the gravity of bodies within the earth to be directly as their distance from the centre, those numbers will also express the relation between its polar and equatorial diameter.

The proportion of the two diameters was calculated by Newton in the following manner. Having found that the centrifugal force at the equator is $\frac{1}{289}$th of gravity, he assumes as an hypothesis, that the axis of

the earth is to the diameter of the equator as 100 to 101, and thence determines what must be the centrifugal force at the equator to give the earth such a form, and finds it to be $\frac{1}{289}$ths of gravity: then, by the rule of proportion, if a centrifugal force, equal to $\frac{4}{289}$ths of gravity, would make the earth higher at the equator than at the poles by $\frac{1}{100}$th of the whole height at the poles, a centrifugal force that is the $\frac{1}{289}$th of gravity will make it higher by a proportional excess, which, by calculation, is $\frac{1}{229}$th of the height at the poles; and thus he discovered that the diameter at the equator is to the diameter at the poles, or the axis, as 230 to 229. But this computation supposes the earth to be every where of an uniform density; whereas if the earth is more dense near the centre, then bodies at the poles will be more attracted by this additional matter being nearer: and therefore the excess of the semi-diameter of the equator above the semiaxis will be different. According to this proportion between the two diameters, Newton farther computes, from the different measures of a degree, that the equatorial diameter will exceed the polar, by 34 miles and $\frac{1}{2}$.

Nevertheless, Messrs. Cassini, both father and son, the one in 1701, and the other in 1713, attempted to prove, in the Memoirs of the Royal Academy of Sciences, that the earth was an oblong spheroid; and in 1718, M. Cassini again undertook, from observations, to show that, on the contrary, the longest diameter passes through the poles; which gave occasion for Mr. John Bernoulli, in his Essai d'une Nouvelle Physique Celeste, printed at Paris in 1735, to triumph over the British philosopher, apprehending that these observations would invalidate what Newton had demonstrated. And in 1720, M. De Mairan advanced arguments, supposed to be strengthened by geometrical demonstrations, farther to confirm the assertions of Cassini. But in 1735, two companies of mathematicians were employed, one for a northern, and another for a southern expedition, the result of whose observations and measurement plainly proved that the earth was flatted at the poles.

The proportion of the equatorial diameter to the polar, as stated by the gentlemen employed on the northern expedition for measuring a degree of the meridian, is as 1 to 0.9891; by the Spanish mathematicians as 266 to 265, or as 1 to 0.99624; by M. Bouguer as 179 to 178, or as 1 to 0.99441.

As to all conclusions deduced from the length of pendulums in different places, it is to be observed, that they proceed upon the supposition of the uniform density of the earth, which is a very improbable circumstance; as justly observed by Dr. Horsley, in his letter to captain Phipps. "You finish your article, he concludes, relating to the pendulum, with saying, 'that these observations gave a figure of the earth nearer to sir Isaac Newton's computation, than any others that have hitherto been made;' and then you state the several figures given, as you imagine, by former observations, and by your own. Now it is very true, that *if* the meridians be ellipses, or *if* the figure of the earth be that of a spheroid generated by the revolution of an ellipsis, turning on its shorter axis, the particular figure, or the ellipticity of the generating ellipsis, which your observations give, is nearer to what sir Isaac Newton saith it should be, if the globe were homogeneous, than any that can be derived from former observations. But yet it is not what you imagine. Taking the gain of the pendulum in latitude 79° 50′, exactly as you state it, the difference between the equatorial and the polar diameter, is about as much less than the Newtonian computation makes it, and the hypothesis of homogeneity would require, as you reckon it to be greater. The proportion of 212 to 211 should, indeed, according to your observations, be the proportion of the force that acts upon the pendulum at the poles, to the force acting upon it at the equator. But this is by no means the same with the proportion of the equatorial diameter to the polar. If the globe were homogeneous, the equatorial diameter would exceed the polar by $\frac{1}{230}$ of the length of the latter: and the polar force would also exceed the equatorial by the like part. But if the difference between the polar and equatorial force be greater than $\frac{1}{230}$ (which may be the case in an heterogeneous globe, and seems to be the case in ours), than the difference of the diameters should, according to theory, be less than $\frac{1}{230}$, and vice versa.

"I confess this is by no means obvious at first sight; so far otherwise, that the mistake, which you have fallen into, was once very general. Many of the best mathematicians were misled by too implicit a reliance upon the authority of Newton, who had certainly confined his investigations to the homogeneous spheroid, and had thought about the heterogeneous only in a loose and general way. The late Mr. Clairault was the first who set the matter right, in his elegant and subtle treatise on the figure of the earth. That work hath now been many years in the hands of mathematicians, among whom I imagine there are none, who have considered the subject attentively, that do not acquiesce in the author's conclusions.

"In the second part of that treatise, it is proved, that putting P for the polar force, Π for the equatorial, δ for the true ellipticity of the earth's figure, and ε for the ellipticity of the homogeneous spheroid.

$\frac{P-\Pi}{\Pi} = 2\varepsilon - \delta$: therefore $\delta = 2\varepsilon - \frac{P-\Pi}{\Pi}$ and, therefore, according to your observation, $\delta = \frac{1}{231}$. This is the just conclusion from your observations on the pendulum, taking it for granted, that the meridians are ellipses: which is an hypothesis, upon which all the reasonings of theory have hitherto proceeded. But, plausible as it may seem, I must say, that there is much reason, from experiment, to call it in question. If it were true, the increment of the force which actuates the pendulum, as we approach the poles, should be as the square of the sine of the latitude: or, which is the same thing, the decrement, as we approach the equator, should be as the square of the co-sine of the latitude. But whoever takes the pains to compare together such of the observations of the pendulum in different latitudes, as seem to have been made with the greatest care, will find that the increments and decrements do by no means follow these proportions: and in those which I have examined, I find a regularity in the deviation which little resembles the mere error of observation. The unavoidable conclusion is, that the true figure of

the meridians is not elliptical. If the meridians are not ellipses, the difference of the diameters may, indeed, or it may not, be proportional to the difference between the polar and the equatorial force; but it is quite an uncertainty, what relation subsists between the one quantity and the other; our whole theory, except so far as it relates to the homogeneous spheroid, is built upon false assumptions, and there is no saying what figure of the earth any observations of the pendulum give."

He then lays down the following table, which shows the different results of observations made in different latitudes; in this the first three columns contain the names of the several observers, the places of observation, and the latitude of each; the fourth column shows the quantity of $P - \Pi$ in such parts as Π is 100000, as deduced from comparing the length of the pendulum at each place of observation, with the length of the equatorial pendulum, as determined by M. Bouguer, upon the supposition that the increments and decrements of force, as the latitude is increased or lowered, observe the proportion which theory assigns; only the second and the last value of $P - \Pi$ are concluded from comparisons with the pendulum at Greenwich and at London, not at the equator. The fifth column shows the value of δ corresponding to every value of $P - \Pi$, according to Clairault's theorem:

Observers.	Places.	Latitudes.	$P-\Pi$	δ
Bouguer	Equator	0° 0′		
Bouguer	Porto Bello	9 34	741.8	$\frac{1}{178}$
Green	Otaheitee	17 29	563.2	$\frac{1}{326}$
Bouguer	San Domingo	18 27	591.0	$\frac{1}{308}$
Abbe' de la Caille	Cape of Good Hope	33 55	731.5	
- - - - -	Paris	48 50	585.1	$\frac{1}{351}$
The Academicians	Pello	66 48	565.9	$\frac{1}{329}$
Capt. Phipps	- - - - - - -	79 50	471.2	$\frac{1}{251}$

"By this table it appears, that the observations in the middle parts of the globe, setting aside the single one at the Cape, are as consistent as could reasonably be expected; and they represent the ellipticity of the earth as about $\frac{1}{310}$. But when we come within 10 degrees of the equator, it should seem that the force of gravity suddenly becomes much less, and within the like distance of the poles much greater, than it could be in such a spheroid."

The following problem communicated by Dr. Leatherland to Dr. Pemberton, and published by Mr. Robertson, serves for finding the proportion between the axis and the equatorial diameter, from measures taken of a degree of the meridian in two different latitudes, supposing the earth an oblate spheroid.

Let *APap* (Plate LIV. Miscel. fig. 83.) be an ellipse representing a section of the earth through the axis *Pp*; the equatorial diameter, or the great axis of the ellipse, being *Aa*; let E and F be two places where the measure of a degree has been taken: these measures are proportional to the radii of curvature in the ellipse at those places; and if CQ, CR, be conjugates to the diameters whose vertices are E and F, CQ will be to CR in the subtriplicate ratio of the radius of curvature at E to that at F, by cor. 1, prop. 4, part 6, of Milnes's Conic Sections, and therefore in a given ratio to one another; also, the angles QCP, RCP, are the latitudes of E and F; so that, drawing QV parallel to *Pp*, and QXYW to *Aa*, these angles being given, as well as the ratio of CQ to CR, the rectilinear figure CVQXRY is given in species; and the ratio of $VC^2 - ZC^2$ $(= QX \times XW)$ to $RZ^2 - QV^2$ $(= RX \times XS)$ is given, which is the ratio of CA^2 to CP^2; therefore the ratio of CA to CP is given.

Hence, if the sine and cosine of the greater latitude be each augmented in the subtriplicate ratio of the measure of the degree in the greater latitude to that in the lesser, then the difference of the squares of the augmented sine, and the sine of the lesser latitude, will be to the difference of the squares of the cosine of the lesser latitude and the augmented cosine, in the duplicate ratio of the equatorial to the polar diameter. For, Cq being taken in CQ equal to CR, and qv drawn parallel to QV, Cv, and vq, CZ and ZR will be the sines and cosines of the respective latitudes to the same radius; and CV, VQ, will be the augmentations of Cv and Cq in the ratio named.

Hence, to find the ratio between the two axes of the earth, let E denote the greater, and F the lesser of the two latitudes, M and N the respective measures taken in each, and let P denote $\sqrt[3]{\frac{M}{N}}$: then

$$\sqrt{\frac{\cos.^2 F - P^2 \times \cos.^2 E}{P^2 \times \sin.^2 E - \sin.^2 F}} \text{ is} = \frac{\text{lesser axis}}{\text{greater axis}}.$$

It also appears by the above problem that when one of the degrees measured is at the equator, the cosine of the latitude of the other being augmented in the subtriplicate ratio of the degrees, the tangent of the latitude will be to the tangent answering to the augmented cosine, in the ratio of the greater axis to the less. For supposing E the place out of the equator; then if the semicircle *Plmnp* be described, and *lc* joined, and *mo* drawn parallel to *aC*: *Co* is the cosine of the latitude to the radius CP, and CY that cosine augmented in the ratio beforenamed: YQ being to *Yl*, that is C*a* to C*n* or C*P*, as the tangent of the angle YCQ, the latitude of the point E, to the tangent of the angle YC*l*, belonging to the augmented cosine. Thus, if M represent the measure in a latitude denoted by E, and N the measure at the equator, let A denote an angle whose measure is

$\cos. E \times \sqrt{\frac{M}{N}}$. Then $\frac{\tan A}{\tan E}$ is $= \frac{\text{lesser axis}}{\text{greater axis}}$.

But M, or the length of a degree, obtained by actual mensuration in different latitudes, is known from the following table:

Names.	*Latit.* ° ′	*Value of M.* toises.	
Maupertuis, &c.	66 20	M=57038	
Cassini and La Caille	49 22	M=57074	
	45 00	M=57050	
Boscovich	43 00	M=56972	
De la Caille	33 18	M=57037	
Juan and Ulloa	00 00	M=56768	at the equator.
Bouguer	00 00	M=56753	
Condamine	00 00	M=56749	

Now, by comparing the first with each of the following ones; the second with each of the following; and, in like manner, the third, fourth, and fifth, with each of the following; there will be obtained 25 results, each showing the relation of the axes or diameters; the arithmetical means of all of which will give that ratio as 1 to 0.9951989.

If the measures of the latitudes of 49° 22′, and of 45°, which fall within the meridian line drawn through France, and which have been re-examined and corrected since the northern and southern expedition, be compared with those of Maupertuis and his associates in the north, and that of Bouguer at the equator, there will result six different values of the ratio of the two axes; the arithmetical mean of all which is that of 1 to 0.9953467, which may be considered as the ratio of the greater axis to the less; which is as 230 to 228.92974, or 215 to 214, or very near the ratio assigned by Newton.

Now, the magnitude as well as the figure of the earth, that is, the polar and equatorial diameters, may be deduced from the foregoing problem. For, as half the latus rectum of the greater axis Aa is the radius of curvature at A, it is given in magnitude from the degree measured there, and thence the axes themselves are given. Thus, the circular arc whose length is equal to the radius being 57.29578 degrees, if this number be multiplied by 56750 toises, the measure of a degree at the equator, as Bouguer has stated it, the product will be the radius of curvature there, or half the latus rectum of the greater axis; and this is to half the lesser axis in the ratio of the less axis to the greater, that is, as 0.9953467 to 1: whence the two axes are 6533820 and 6564366 toises, or 7913 and 7950 English miles; and the difference between the two axis about 37 miles.

And very nearly the same ratio is deduced from the lengths of pendulums vibrating in the same time, in different latitudes; provided it be again allowed that the meridians are real ellipses, or the earth a true spheriod, which, however, can only take place in the case of an uniform gravity in all parts of the earth.

Thus, in the new Petersburgh acts, for the years 1788 and 1789, are accounts and calculations of experiments relative to this subject, by M. Krafft. These experiments were made at different times, and in various parts of the Russian empire. This gentleman has collected and compared them, and drawn the proper conclusions from them: thus he infers that the length x of a pendulum that swings seconds in any given latitude λ, and in a temperature of 10 degrees of Reaumur's thermometer, may be determined by this equation:

$x = 439.178 + 2.321 \sin^2\lambda$. lines of a French foot.. or $x = 39.0045 + 0.206 \sin^2\lambda$. in English inches, in the temperature of 53 of Fahrenheit's thermometer.

This expression nearly agrees, not only with all the experiments made on the pendulum in Russia, but also with those of Mr. Graham in England, and those of Mr. Lyons in 79° 50′ north latitude, where he found its length to be 431.38 lines. It also shows the augmentation of gravity from the equator to the parallel of a given latitude λ: for, putting g for the gravity under the equator, G for that under the pole, and y for that under the latitude λ, M. Krafft finds

$y = (1 + 0.0052848 \sin^2\lambda)\, g$; and therefore $G = 1.0052848 g$.

From this proportion of gravity under different latitudes, the same author infers that, in case the earth is a homogeneous ellipsoid, its oblateness must be $\frac{1}{191}$; instead of $\frac{1}{230}$, which ought to be the result of this hypothesis: but on the supposition that the earth is a heterogenious ellipsoid, he finds its oblateness, as deduced from these experiments, to be $\frac{1}{257}$; which agrees with that resulting from the measurement of some of the degrees of the meridian. This confirms an observation of M. De la Place, that if the hypothesis of the earth's homogeneity is given up, then theory, the measurement of degrees of latitude, and experiments with the pendulum, all agree in their result with respect to the oblateness of the earth.

In the Philos. Trans. for 1791, Mr. Dalby has given some calculations on measured degrees of the meridian, whence he infers, that those degrees measured in middle latitudes, will answer nearly to an ellipsoid whose axes are in the ratio assigned by Newton, viz. that of 230 to 229. And as the deviations of some of the others, viz. towards the poles and equator, he thinks they are caused by the errors in the observed celestial arcs.

EARTH, MAGNETISM OF. The notion of the magnetism of the earth was started by Gilbert; and Boyle supposes magnetic effluvia moving from one pole to the other. See MAGNETISM.

EARTH, MAGNITUDE OF. This has been variously determined by different authors, both ancient and modern. The usual way has been, to measure the length of one degree of the meridian, and multiply it by 360, for the whole circumference. Diogenes Laertius informs us, that Anaximander, a scholar of Thales, who lived about 550 years before the birth of Christ, was the first who gave an account of the circumference of the sea and land; and it seems his measure was used by the succeeding mathematicians, till the time of Eratosthenes. Aristotle, at the end of lib. 2 De Cœlo, says, the mathematicians who have attempted to measure the circuit of the earth, make it 40000 stadia: which, it is thought, is the number determined by Anaximander.

Snellius relates, from the Arabian geographer Abulfedea, who lived about the 1300th year of Christ, that about the 800th year of Christ, Almaimon, an Arabian king, having collected together some skilful mathematicians, commanded them to find out the circumference of the earth. Accordingly these made choice of the fields of Mesopotamia, where they measured under the same meridian from north to south, till the pole was depressed one degree lower: which measure they found equal to 56 miles, or $56\frac{2}{3}$: so that, according to them, the circuit of the earth is 20160 or 20340 miles.

It was a long time after this before any more attempts were made in this business. At length, however, Mr. Snell, professor of mathematics at Leyden, about the year 1620, with great skill and labour, by measuring large distances between two parallels, found one degree equal to 28500 perches, each of which is 12 Rhinland feet, amounting to 19 Dutch miles, and so the whole periphery 6840 miles; a mile being, according to him, 1500 perches, or 18000 Rhinland feet.

The next that undertook this measurement, was Richard Norwood, who, in the year 1635, by measuring the distance from London to York with a chain, and taking

the sun's meridian altitude, June 11th, old style, with a sextant of about 5 feet radius, found a degree contained 367200 feet, or 69 miles and a half and 14 poles; and thence the circumference of a great circle of the earth is a little more than 25036 miles, and the diameter a little more than 7966 miles. See the particulars of this measurement in his Seaman's Practice.

The measurement of the earth by Snell, though very ingenious and troublesome, and much more accurate than any of the ancients', being still thought, by some French mathematicians, liable to certain small errors, the inquiry was renewed, after Snell's manner, by Picard and other mathematicians, by the king's command, using a quadrant of $3\frac{1}{6}$ French feet radius; by which they found a degree contained 542360 French feet.

M. Cassini the younger, in the year 1700, by the king's command also, renewed the experiment with a quadrant of 10 feet radius, for taking the latitude, and another of $3\frac{1}{8}$ feet for taking the angle of the triangles; and found a degree, from his calculation, contained 27292 toises, or almost $69\frac{1}{2}$ English miles.

From the mean of a great many measurements, the following dimensions may be taken as near the truth:

the circumference	25000 miles,
the diameter	$7957\frac{3}{4}$ miles,
the superficies	198944206 square miles
the solidity	263930000000 cubic miles.

Also, the seas and unknown parts of the earth, by a measurement of the best maps, contain 160522026 square miles: the inhabited parts 38922180; of which Europe contains 4456065; Asia, 10768823; Africa, 9654807; and America, 14110874.

EARTH, STRUCTURE OF. After the preceding survey of the form and magnitude of this globe of earth, the next object of attention is the general arrangement of those substances of which it is composed. These are neither disposed in a regular series, according to their specific gravities, nor yet thrown together in total disorder, as if by accident or chance. Human industry has hitherto been able to penetrate but a very little way into the bowels of the earth, and we can but know little of its interior parts. The depth of the earth, from the surface to the centre, is nearly four thousand miles; and yet the deepest mine in Europe, that at Cottenberg, in Hungary, is not more than one thousand yards deep; "the greatest depth, therefore," says an excellent writer, "to which avarice has ever yet penetrated, may be compared to the puncture made in the body of an elephant by the proboscis of a gnat."

From what has been discovered, however, of those parts which lie most contiguous to our observation, naturalists have compared the structure of the earth to the leaves of a book, or the coats of an onion. Except, indeed, in some of those immense mountains, which have existed from the creation, or at least from the deluge, where the matter, from whatever cause, is more homogeneous, the earth is found to consist of various strata, or layers, which differ according to the circumstances of climate and situation. The surface, in general, evidently consists of a confused mixture of decayed animal and vegetable substances and earths rudely united together; but when we have penetrated below the surface, we find the materials of the globe arranged in a more regular manner. Sometimes, indeed, we find heaps of stone, which do not consist of layers, but are confused masses of unequal thickness, and are called rocks. The strata are, in general, extended through a whole country, and perhaps, with some interruptions and varieties, through the globe itself. These extensive bodies are found most regular when the country is flat, being, in that case, nearly parallel to the horizon, though frequently dipping downwards in a certain angle; in many places the beds have a wave, as where the country consists of gently waving hills and vales; here, too, they generally dip. In travelling a mile we, perhaps, pass through ground composed mostly of sand; in another mile we find it, perhaps, composed of clay; and this is occasioned by the edges of the different strata lying with an obliquity to the horizon. By the same kind of projection, mountains, or ridges of mountains, are produced, which, in general, have what is called a back and a face, the former smoother, and the latter more rugged. We generally find, too, on one side of a mountain, a more gradual ascent than on the other; which is occasioned by the strata, which have risen above the general level of the country, being abruptly broken off.

Dr. Woodward has considered the circumstances of these strata with great attention, viz. their order, number, situation with respect to the horizon, depth, intersections, fissures, colour, consistence, &c. He ascribes the origin and formation of them all, to the great flood or cataclysmus. At that terrible revolution he supposes that all sorts of terrestrial bodies had been dissolved and mixed with the waters, forming altogether a chaos or confused mass. This mass of terrestrial particles, intermixed with water, he supposes, was at length precipitated to the bottom; and that generally according to the order of gravity, the heaviest sinking first, and the lightest afterwards. By such means were the strata formed of which the earth consists; which, attaining their solidity and hardness by degrees, have continued distinct ever since. These sediments, he farther concludes, were at first all parallel and concentrical; and the surface of the earth formed of them, perfectly smooth and regular; but that, in course of time, divers changes happening, from earthquakes, volcanos, &c. the order and regularity of the strata were disturbed and broken, and the surface of the earth, by such means, brought to the irregular form in which it now appears.

M. De Buffon surmises that the earth, and the other planets, are also parts struck off from the body of the sun by the collision of comets; and that, when the earth assumed its form, it was in a state of liquefaction by fire. But that could not be the method of producing the planets; for if they were struck off from the body of the sun, they would move in orbits that would pass through the sun, instead of having the sun for their focus, or centre, as they are now found; so that having been struck off, they would fall down into the sun again, terminating their career, as it were, after one revolution only. See GEOLOGY.

EARTH, *its quantity of matter, density, and attractive power.* Although the relative densities of the earth and most of the other planets have been known a considerable time, it is but very lately that we have come to the knowledge of the absolute gravity or density of the

whole mass of the earth. This has been calculated and deduced from the observations made by Dr. Maskelyne, at the mountain Schehallien, in the years 1774, 5, and 6. The attraction of that mountain on a plummet, was observed on both sides of it, and its mass computed from a number of sections in all directions, and consisting of stone; these data being then compared with the known attraction and magnitude of the earth, gave, by proportion, its mean density, which is to that of water as 9 to 2, and to common stone as 9 to 5: from which very considerable mean density, it may be presumed that the internal parts contain some great quantities of metals.

From the density now found, its quantity of matter becomes known, being equal to the product of its density by its magnitude. From various experiments, too, we know that its attractive force, at the surface, is such, that bodies fall there through a space of about $16\frac{1}{12}$ feet in the first second of time: whence the force at any other place, either within or without it, becomes known; for the force at any part within it, is directly as its distance from the centre; but the force of any part without it, reciprocally as the square of its distance from the centre.

Earth, Motion of the. It is now generally granted that, besides the small motion of the earth which causes the precession of the equinoxes, the earth has two great and independant motions; viz. the one by which it turns round its own axis, in the space of 24 hours nearly, and causing the continual succession of day and night; and the other, an absolute motion of its whole mass in a large orbit about the sun, having that luminary for its centre, in such manner that its axis keeps always parallel to itself, inclined in the same angle to its path, and, by that means, causing the vicissitudes of seasons; spring, summer, autumn, winter.

It is, indeed, true, that, as to sense, the earth appears to be fixed in the centre, with the sun and stars moving round it every day; and such, doubtless, would be considered as the true nature of the motions in the rude ages of mankind, as they are still by the rude and unlearned. But, to a thinking and learned mind, the contrary will soon appear.

By the diurnal rotation of the earth on its axis, the same phenomena will take place as if it had no such motion, and as if the sun and stars moved round it. For, turning round from west to east, causes the sun and all the visible heavens to seem to move the contrary way, or from east to west, as we daily see them do. So, when in its rotation it has brought the sun or a star to appear just in the horizon in the east, they are then said to be rising; and as the earth continues to remove more and more towards the east, other stars seem to rise and advance westwards, passing the meridian of the observer, when they are due south from him, and at their greatest altitude above his horizon; after which, by a continuance of the same motions, viz. of the earth's rotation eastwards, and the luminaries' apparent countermotion westwards, these decline from the meridian, or south point, towards the west, where being arrived, they are said to set and descend below it; and so on continually from day to day; thus making it day while the sun is above the horizon, and night while he is below it.

While the earth is thus turning on its axis, it is, at the same time, carried by its proper motion in its orbit round the sun, as one of the planets; namely, between the orbits of Venus and Mars: having the orbits of Venus and Mercury within its own, or between it and the sun, in the centre, and those of Mars, Jupiter, Saturn, &c. without or above it; which are, therefore, called superior planets, and the others, inferior ones. This is called the annual motion of the earth, because it is performed in a year, or 365 days 6 hours nearly; or rather 365 days, 5 hours, and 49 minutes, from any equinox or solstice to the same again, making the tropical year; but from any fixed star to the same again, as seen from the sun, in 365 days, 6 hours, 9 minutes, which is called the sidereal year. The figure of this orbit is elliptical, having the sun in one focus, the mean distance being about 95 millions of miles; which is upon the supposition that the sun's parallax is about $8''\frac{2}{3}$ or the angle under which the earth's semidiameter would appear to an observer placed in the sun; and the eccentricity of the orbit, or distance of the sun, in the focus, from the centre of this elliptic orbit, is about $\frac{1}{60}$th of the mean distance.

EARTHS. The word earth in common language, has two meanings: it sometimes signifies, as we have seen, the globe which we inhabit, and sometimes the mould on which vegetables grow. Chemists have examined this mould, and have found that it consists of a variety of substances mixed together, without order or regularity. The greatest part of it, however, as well as of the stones which form apparently so large a proportion of the globe, consist of a small number of bodies, which have a variety of common properties. These bodies chemists have agreed to class together, and to denominate earths.

Every body which possesses the following properties is an earth.

1. Insoluble in water, or nearly so; or at least becoming insoluble when combined with carbonic acid. 2. Little or no taste or smell; at least when combined with carbonic acid. 3. Fixed, incombustible, and incapable while pure of being altered by the fire. 4. A specific gravity not exceeding 4.9. 5. When pure, capable of assuming the form of a white powder. 6. Not altered when heated with combustibles.

The earths at present known, are nine in number, namely,

1. Barytes.
2. Strontian.
3. Lime.
4. Magnesia.
5. Alumina.
6. Yttria.
7. Glucina.
8. Zirconia.
9. Silica.

Which see under their respective names.

Every one of the above characteristics is not, perhaps, rigorously applicable to each of these bodies; but all of them possess a sufficient number of common properties to render it useful to arrange them under one class.

Earth Nuts, or *Ground Nuts*. See Arachis.

EARTHQUAKES. When we consider the very formidable nature of these phenomena, we cannot wonder that human ingenuity has been often exercised in accounting for their causes. To explain the theory of earthquakes, it will be necessary to recal to the reader's

attention what was said in the preceding article on the structure of the earth, which, being formed of different strata, we compared to the leaves of a book or the coats of an onion; and if with this consideration we combine the operation of subterraneous fires, we shall have at least a probable explanation of the cause of earthquakes.

The sudden explosions which take place from volcanoes, probably depend on the access of a quantity of water, which enters through some fissure communicating with the sea, or which is derived from other sources in the earth. If this mass of water is sufficiently great, it will extinguish the volcano; if not, it will be converted into steam, the expansive force of which far exceeds that of gunpowder. The elastic fluid thus formed either finds vent at the mouth of the volcano, or, if the superincumbent weight should be too great, it will force a passage between the strata of the earth, and occasion that undulatory, but sometimes violent, motion, which is called an earthquake. From various facts demonstrative of the cohesion and elasticity of bodies, we are warranted in concluding, that the different strata of which the earth is composed will adhere together, and that a freer passage will be afforded to any intervening body between the strata than directly through them. If the confined fire or steam acts directly under a province or town, it will heave the earth perpendicularly upwards, and the shocks will be more sudden and violent. If it acts at a distance, it will raise that tract obliquely; and the motion will be more oblique, undulatory, and tremulous:

The great earthquake at Lisbon, in 1755, was felt as far as Scotland; and from the phenomena which attended it, it was evident, that the ground had a waving motion from south to north. All the oblong lakes that lay from north to south were much agitated, the wave commencing at the south end; whilst all other lakes which lay across, from east to west, were much less affected.

The great distance to which earthquakes extend, depends on the compressibility and elasticity of the earth; which may be understood from the vibration of the walls of houses, occasioned by the passing of carriages in the adjacent streets. Another instance is the vibration of steeples by the ringing of bells or gusts of wind. The Eddistone lighthouse often vibrates from the force of the waves which beat against its foundation.

Previous to an eruption of Vesuvius, the earth always trembles, and subterraneous explosions are heard. On the 1st of November 1755, the era so fatal to Lisbon, the island of Madeira was violently shaken by an earthquake, accompanied with subterraneous explosions. So thoroughly convinced, indeed, are the inhabitants of volcanic countries, of the connection between earthquakes and volcanoes, that when a great eruption takes place from a volcano, they congratulate themselves on having escaped an earthquake.

Earthquakes, as well as volcanic eruptions, are always preceded by a violent agitation of the sea. Previous to the breaking out of Vesuvius, the sea retires from the adjacent shores till the mountain is burst open, and then it returns with such impetuosity as to overflow its usual boundary. About an hour after the first shocks, which alarmed the city of Lisbon in 1755, the sea was observed to come rushing towards the city like a torrent, though against both wind and tide: it rose forty feet higher than was ever known, and as suddenly subsided. A ship, fifty leagues off at sea, received so violent a shock as greatly to injure the deck, &c. The same effect was observed at Cadiz, and at a number of ports throughout the Mediterranean; and, indeed, more or less, all over Europe.

That earthquakes are the effect of steam generated within the bowels of the earth, and that they are produced in the manner which has been described, appears highly probable from the quantities of boiling water which have occasionally been thrown up by volcanoes in different parts of the world. In 1631 and 1698, vast torrents of boiling water flowed from the crater of Vesuvius, previous to the eruption of fire; and what was, perhaps, still more remarkable, many species of sea-shells, in a calcined state, were found on the brink of the crater, and also in the channel formed by the flood. The same thing happened at Ætna, in 1755, when a dreadful torrent of boiling water flowed from the crater at the time of an eruption of fire. Sir William Hamilton observes, that the sea-shells emitted along with the water clearly indicate a communication with the sea. All warm springs probably receive their heat from the action of pyrites, near which the water passes.

Authors of very high repute have, however, attributed earthquakes entirely to the agency of the electric fluid, and regarded them chiefly as violent shocks of electricity. We must confess there is indeed an intimate, though hitherto inexplicable, connection between earthquakes and even volcanoes, and the electric fluid; and the state of the atmosphere previous either to an earthquake or a volcanic eruption is always highly electrical.

Though there is hardly any country known in which shocks of an earthquake have not at some time or other been felt, yet there are some much more subject to them than others. It has been observed, that northern countries in general are less subject to earthquakes than those situated near the equator, or in the southern latitudes; but this does not hold universally. Islands are also more subject to earthquakes than continents; but neither does this hold without exceptions. Some particular parts of continents, and some particular islands, are more subject to them than others lying in the neighbourhood, and differing very little from them in external appearance. Thus, Portugal is more subject to earthquakes than Spain, and the latter much more than France; Mexico and Peru more than the other countries of America; and Jamaica more than the other Caribbee islands. Earthquakes are frequent, though not often violent, in Italy; but in Sicily they are often terribly destructive. Asia Minor has been remarkably subject to them from the remotest antiquity; and the city of Antioch in particular has suffered more from earthquakes than any other in that country. The same phenomena are said also to occur very frequently in the north-eastern extremities of Asia, even in very high latitudes.

From the observations that have been made, the following phenomenon respecting earthquakes may be deduced, and reckoned pretty certain:

I. Where there are any volcanoes or burning mountains, earthquakes may reasonably be expected more

frequently than in other countries. 2. If the volcano has been for a long time quiet, a violent earthquake is to be feared, and vice versa: but to this there are many exceptions. 3. Earthquakes are generally preceded by long droughts; but they do not always come on as soon as the drought ceases. 4. They are also preceded by electrical appearances in the air; such as the aurora borealis, falling stars, &c. but this does not hold universally. 5. A short time before the shock, the sea swells up and makes a great noise; fountains are troubled, and send forth muddy water; and the beasts seem frightened, as if sensible of an approaching calamity. 6. The air at the time of the shock is generally calm and serene, but afterwards commonly becomes obscure and cloudy. 7. The shock comes on with a rumbling noise, sometimes like that of carriages; sometimes a rushing noise like wind, and sometimes explosions like the firing of cannon, are heard: sometimes the ground heaves perpendicularly upwards, and sometimes rolls from side to side; sometimes the shock begins with a perpendicular heave, after which the other kind of motion commences. A single shock is but of very short duration, the longest scarcely lasting a minute; but they frequently succeed each other at short intervals for a considerable length of time. 8. During the shock, chasms are made in the earth, from which sometimes flames, but oftener great quantities of water, are discharged. Flame and smoke are also emitted from parts of the earth where no chasms can be perceived. Sometimes these chasms are but small; but in violent earthquakes they are frequently so large, that whole cities sink down into them at once. 9. The water of the ocean is affected even more than the dry land. The sea swells to a prodigious height, much more than we could suppose it raised by the mere elevation of its bottom by the shock. Sometimes it is divided to a considerable depth; and quantities of air, flames, and smoke, are discharged from it. The like irregular agitations happen to the waters of ponds, lakes, and even rivers. 10. The shock is felt at sea as well as on land. Ships are affected by a sudden stroke, as if they had run aground, or struck upon a rock. 11. The effects of earthquakes are not confined to one particular district or country, but often extend, as was already intimated, to very distant regions; though no earthquakes has yet been known extensive enough to affect the whole globe at one time. In those places also where the shock is not felt on dry land, the irregular agitation of the waters is perceived very remarkably.

All these positions are verified by the accounts of those earthquakes which have been particularly described by witnesses of the best character. But above all, the great earthquake which happened on the 1st of November 1755, affords the clearest example of all the phenomena we have mentioned; having been felt violently in many places both on land and at sea, and extended its effects to the waters in many other places where the shocks were not perceived. At Lisbon in Portugal its effects were most severe.

The following account of that terrible phenomenon, by an eye-witness, is extracted from a volume of letters, published a few years ago by the Rev. Mr. Davy:

"There never was a finer morning seen than the 1st of November 1755: the sun shone out in his full lustre; the whole face of the sky was perfectly serene and clear; and not the least signal or warning of that approaching event, which has made this once flourishing, opulent, and populous city, (Lisbon) a scene of the utmost horror and desolation, except only such as served to alarm, but scarcely left a moment's time to fly from the general destruction.

"It was on the morning of this fatal day, between the hours of nine and ten, that I was sat down in my apartment, just finishing a letter, when the papers and table I was writing on began to tremble with a gentle motion, which rather surprised me, as I could not perceive a breath of wind stirring: whilst I was reflecting with myself what this could be owing to, but without having the least apprehension of the real cause, the whole house began to shake from the very foundation, which at first I imputed to the rattling of several coaches in the main street, which usually passed that way at this time from Belem to the palace; but on hearkening more attentively, I was soon undeceived, as I found it was owing to a strange frightful kind of noise under ground, resembling the hollow distant rumbling of thunder. All this passed in less than a minute; and I must confess I now began to be alarmed, as it naturally occurred to me, that this noise might possibly be the forerunner of an earthquake, as one I remembered, which had happened about six or seven years ago, in the island of Madeira, commenced in the same manner, though it did little or no damage.

"Upon this I threw down my pen, and started upon my feet, remaining for a moment in suspense, whether I should stay in the apartment, or run into the street, as the danger in both places seemed equal; and still flattering myself that this tremor might produce no other effects than such inconsiderable ones as had been felt at Madeira; but in a moment I was roused from my dream, being instantly stunned with a most horrid crash, as if every edifice in the city had tumbled down at once. The house I was in shook with such violence, that the upper stories immediately fell; and though my apartment (which was the first floor) did not then share the same fate, yet every thing was thrown out of its place in such a manner, that it was with no small difficulty I kept my feet, and expected nothing less than to be soon crushed to death, as the walls continued rocking to and fro in the most frightful manner, opening in several places, large stones falling down on every side from the cracks, and the ends of most of the rafters starting out from the roof. To add to this terrifying scene, the sky in a moment became so gloomy, that I could now distinguish no particular object; it was an Egyptian darkness indeed, such as might be felt; owing, no doubt, to the prodigious clouds of dust and lime, raised from so violent a concussion, and as some reported, to sulphureous exhalations; but this I cannot affirm: however, it is certain I found myself almost choaked for near ten minutes.

"As soon as the gloom began to disperse, and the violence of the shock seemed pretty much abated, the first object I perceived in the room was a woman sitting on the floor, with an infant in her arms, all covered with dust, pale, and trembling; I asked her how she got hither; but her consternation was so great, that she could

give me no account of her escape. I supposed that when the tremor first began, she ran out of her own house, and finding herself in such imminent danger from the falling of stones, retired into the door of mine, which was almost contiguous to hers, for shelter; and when the shock increased, which filled the door with dust and rubbish, ran into my apartment, which was then open: be it as it might, this was no time for curiosity. I remember the poor creature asked me, in the utmost agony, if I did not think the world was at an end; at the same time she complained of being choaked, and begged for God's sake I would procure her a little drink; upon which I went to a closet where I kept a large jar with water (which you know is sometimes a pretty scarce commodity in Lisbon), and finding it broken to pieces, I told her she must not now think of quenching her thirst, but saving her life, as the house was just falling on our heads, and if a second shock came, would certainly bury us both. I bade her take hold of my arm, and that I would endeavour to bring her into some place of security.

"I shall always look upon it as a particular providence that I happened on this occasion to be undressed; for had I dressed myself, as I proposed, when I got out of bed, in order to breakfast with a friend, I should, in all probability, have run into the street at the beginning of the shock, as the rest of the people in the house did, and consequently have had my brains dashed out, as every one of them had. However, the imminent danger I was in did not hinder me from considering that my present dress, only a gown and slippers, would render my getting over the ruins almost impracticable: I had, therefore, still presence of mind enough left to put on a pair of shoes and a coat, the first that came in my way, which was every thing I saved; and in this dress I hurried out, the woman with me, holding by my arm, and made directly to that end of the street which opens to the Tagus; but finding the passage this way entirely blocked up with the fallen houses to the height of their second stories, I turned back to the other end which led into the main street (the common thoroughfare to the palace); and having helped the woman over a vast heap of ruins, with no small hazard to my own life, just as we were going into the street, as there was one part I could not well climb over without the assistance of my hands as well as feet, I desired her to let go her hold, which she did, remaining two or three feet behind me, at which time there fell a vast stone from a tottering wall, and crushed both her and the child in pieces. So dismal a spectacle at any other time would have affected me in the highest degree; but the dread I was in of sharing the same fate myself, and the many instances of the same kind which presented themselves all around, were too shocking to make me dwell a moment on this single object.

"I had now a long narrow street to pass, with the houses on each side four or five stories high, all very old, the greater part already thrown down, or continually falling, and threatening the passengers with inevitable death at every step, numbers of whom lay killed before me, or, what I thought far more deplorable, so bruised and wounded, that they could not stir to help themselves. For my own part, as destruction appeared to me unavoidable, I only wished I might be made an end of at once, and not have my limbs broken; in which case I could expect nothing else but to be left upon the spot, lingering in misery, like these poor unhappy wretches, without receiving the least succour from any person.

"As self-preservation, however, is the first law of nature, these sad thoughts did not so far prevail as to make me totally despair. I proceeded on as fast as I conveniently could, though with the utmost caution; and having at length got clear of this horrid passage, I found myself safe and unhurt in the large open space before St. Paul's church, which had been thrown down a few minutes before, and buried a great part of the congregation, which was generally pretty numerous, this being reckoned one of most populous parishes in Lisbon. Here I stood some time, considering what I should do; and not thinking myself safe in this situation, I came to the resolution of climbing over the ruins of the west end of the church, in order to get to the river-side, that I might be removed as far as possible from the tottering houses, in case of a second shock.

"This with some difficulty I accomplished; and here I found a prodigious concourse of people, of both sexes, and of all ranks and conditions, among whom I observed some of the principal canons of the patriarchal church, in their purple robes and rochets, as these all go in the habit of bishops; several priests, who had run from the altars in their sacerdotal vestments, in the midst of their celebrating mass; ladies half-dressed, and some without shoes; all these, whom their mutual dangers had here assembled as to a place of safety, were on their knees at prayers, with the terrors of death in their countenances, every one striking his breast, and crying out incessantly, *Miserecordia meu Dios.*

"In the midst of our devotions, the second great shock came on, little less violent than the first, and completed the ruin of those buildings which had been already much shattered. The consternation now became so universal, that the shrieks and cries of *Miserecordia* could be distinctly heard from the top of St. Catherine's hill, at a considerable distance off, whither a vast number of people had likewise retreated: at the same time we could hear the fall of the parish-church there, whereby many persons were killed on the spot, and others mortally wounded. You may judge of the force of this shock, when I inform you it was so violent that I could scarcely keep on my knees; but it was attended with some circumstances still more dreadful than the former. On a sudden I heard a general outcry, 'The sea is coming in; we shall be all lost.' Upon this, turning my eyes towards the river, which in that place is near four miles broad, I could perceive it heaving and swelling in a most unaccountable manner, as no wind was stirring: in an instant there appeared, at some small distance, a large body of water, rising like a mountain; it came on foaming and roaring, and rushed towards the shore with such impetuosity, that we all immediately ran for our lives as fast as possible: many were actually swept away, and the rest above their waist in water at a good distance from the banks. For my own part, I had the narrowest escape, and should certainly have been lost, had I not grasped a large beam that lay on the ground,

till the water returned to its channel, which it did almost at the same instant with equal rapidity. As there now appeared at least as much danger from the sea as the land, and I scarcely knew whither to retire for shelter, I took a sudden resolution of returning back, with my clothes all dropping, to the area of St. Paul's: here I stood some time, and observed the ships tumbling and tossing about, as in a violent storm: some had broken their cables, and were carried to the other side of the Tagus; others were whirled round with incredible swiftness; several large boats were turned keel upwards; and all this without any wind, which seemed the more astonishing. It was at the time of which I am now speaking, that the fine new quay, built of rough marble, at an immense expense, was entirely swallowed up, with all the people on it, who had fled thither for safety, and had reason to think themselves out of danger in such a place: at the same time a great number of boats and small vessels, anchored near it (all likewise full of people, who had retired thither for the same purpose), were all swallowed up, as in a whirlpool, and never more appeared.

"This last dreadful incident I did not see with my own eyes, as it passed three or four stone's-throws from the spot where I then was; but I had the account as here given from several masters of ships, who were anchored within two or three hundred yards of the quay, and saw the whole catastrophe. One of them informed me, that when the second shock came on, he could perceive the whole city waving backwards and forwards, like the sea when the wind first begins to rise; that the agitation of the earth was so great, even under the river, that it threw up his large anchor from the mooring, which swam, as he termed it, on the surface of the water; that immediately upon this extraordinary concussion, the river rose at once near 20 feet, and in a moment subsided; at which instant he saw the quay, with the whole concourse of people upon it, sink down, and at the same time every one of the boats and vessels that were near it were drawn into the cavity, which he supposes instantly closed upon them, inasmuch as not the least sign of a wreck was ever seen afterwards. This account you may give full credit to; for as to the loss of the vessels, it is confirmed by every body; and with regard to the quay, I went myself a few days after to convince myself of the truth, and could not find even the ruins of a place, where I had taken so many agreeable walks, as this was the common rendezvous of the factory in the cool of the evening. I found it all deep water, and in some parts scarcely to be fathomed.

"This is the only place which I could learn was swallowed up in or about Lisbon, though I saw many large cracks and fissures in different parts; and one odd phenomenon I must not omit, which was communicated to me by a friend, who had a house and wine-cellers on the other side of the river, viz. that the dwelling-house being first terribly shaken, which made all the family run out, there presently fell down a vast high rock near it; that upon this the river rose and subsided in the manner already mentioned, and immediately a great number of small fissures appeared in several contiguous pieces of ground, whence there spouted out like a jet-d'eau a large quantity of fine white sand, to a prodigious height.

"I had not been long in the area of St. Paul's, when I felt the third shock; which though somewhat less violent than the two former, the sea rushed in again, and retired with the same rapidity, and I remained up to my knees in water, though I had gotten upon a small eminence at some distance from the river, with the ruins of several intervening houses to break its force. At this time I took notice the waters retired so impetuously, that some vessels were left quite dry, which rode in seven fathom water. The river thus continued alternately rushing on and retiring several times together, in such sort, that it was justly dreaded Lisbon would now meet the same fate which, in 1746, had befallen the city of Lima.

"Perhaps you may think the present doleful subject here concluded: but, alas! the horrors of the first of November are sufficient to fill a volume. As soon as it grew dark, another scene presented itself little less shocking than those already described. The whole city appeared in a blaze, which was so bright that I could easily see to read by it. It may be said, without exaggeration, it was on fire at least in a hundred different places at once, and thus continued burning for six days together, without intermission, or the least attempt being made to stop its progress.

"I could never learn that this terrible fire was owing to any subterraneous eruption, as some have reported, but to three causes, which all concuring at the same time, will naturally account for the prodigious havoc it made. The first of November being All Saints day, a high festival among the Portuguese, every altar in every church and chapel (some of which have more than twenty) was illuminated with a number of wax tapers and lamps, as customary: these setting fire to the curtains and timber-work that fell with the shock, the conflagration soon spread to the neighbouring houses; and being there joined with the fires in the kitchen chimneys, increased to such a degree, that it might easily have destroyed the whole city, though no other cause had concurred, especially as it met with no interruption.

"But what would appear incredible to you, were the fact less public and notorious, is, that a gang of hardened villains, who had been confined, and got out of prison when the wall fell, at the first shock, were busily employed in setting fire to those buildings which stood some chance of escaping the general destruction!

"The fire, by some means or other, may be said to have destroyed the whole city, at least every thing that was grand or valuable in it; and the damage on this occasion is not to be estimated.

"The whole number of persons that perished, including those who were burnt, or afterwards crushed to death whilst digging in the ruins, is supposed, on the lowest calculation, to amount to more than sixty thousand; and though the damage in other respects cannot be computed, yet you may form some idea of it, when I assure you, that this extensive and opulent city is now nothing but a vast heap of ruins; that the rich and poor are at present upon a level; some thousands of families which but the day before had been easy in their circumstances, being

now scattered about in the fields, wanting every conveniency of life, and finding none able to relieve them.

"A few days after the first consternation was over, I ventured down into the city, by the safest ways I could pick out, to see if there was a possibility of getting any thing out of my lodgings; but the ruins were now so augmented by the late fire, that I was so far from being able to distinguish the individual spot where the house stood, that I could not even distinguish the street, amidst the mountains of stone and rubbish which rose on every side. Some days after, I ventured down again with several porters, who, having long plied in these parts of the town, were well acquainted with the situation of particular houses: by their assistance, I at last discovered the spot; but was soon convinced, that to dig for any thing there, besides the danger of such an attempt, would never answer the expense.

"On both the times when I attempted to make this fruitless search, especially the first, there came such an intolerable stench from the dead bodies, that I was ready to faint away; and though it did not seem so great this last time, yet it had nearly been more fatal to me, as I contracted a fever by it, but of which, God be praised, I soon got the better. However, this made me so cautious for the future, that I avoided passing near certain places, where the stench was so excessive that people began to dread an infection. A gentleman told me, that going into the town a few days after the earthquake, he saw several bodies lying in the streets, some horribly mangled, as he supposed, by the dogs, others half-burnt, some quite roasted; and that in certain places, particularly near the doors of churches, they lay in vast heaps, piled one upon another."

The year 1783 was fatally marked by the desolation of some of the most fertile, most beautiful, and most celebrated provinces of Europe. The two Calabrias, with a part of Sicily, were doomed to be a scene of the most tremendous and the most fatal earthquakes that ever were known, even in those volcanic regions. The first shock happened about noon, on the 5th of February, and was so violent as to involve almost the whole of Calabria in ruin. This was but the commencement of a succession of earthquakes, which, beginning from the city of Amantea, on the coast of the Tyrrhene sea, proceeded along the western coast to Cape Spartivento, and up the eastern as far as Cape d'Alice; during the whole of which space not a town was left undistroyed.

During two years repeated shocks continued to agitate the affrighted minds of the inhabitants of Calabria and Sicily: but the principal mischief arose in the months of February and March in the first year. For several months the earth continued in an unceasing tremor, which at certain intervals increased to violent shocks, some of which were beyond description dreadful. These shocks were sometimes horizontal, whirling like a vortex; and sometimes by pulsations or beating from the bottom upwards: and were at times so violent, that the heads of the largest trees almost touched the ground on either side. The rains during a great part of the time were continual and violent, often accompanied with lightning and furious gusts of wind. All that part of Calabria, which lay between the 38th and 39th degrees, assumed a new appearance. Houses, churches, towns, cities, and villages, were buried in one promiscuous ruin. Mountains were detached from their foundations, and carried to a considerable distance. Rivers disappeared from their beds, and again returned and overflowed the adjacent country. Streams of water suddenly gushed out of the ground, and sprang to a considerable height. Large pieces of the surface of the plain, several acres in extent, were carried five hundred feet from their former situation down into the bed of the river, and left standing at nearly the distance of a mile, surrounded by large plantations of olives and mulberry-trees, and corn growing as well upon them as upon the ground from which they were separated. Amidst these scenes of devastation, the escape of some of the unhappy sufferers is extremely wonderful. Some of the inhabitants of houses which were thrown to a considerable distance, were dug out from their ruins unhurt. But these instances were few; and those who were so fortunate as to preserve their lives in such situations, were content to purchase existence at the expense of broken limbs and the most dreadful contusions.

During this calamitous scene, it is impossible to conceive the horrors and wretchedness of the unhappy inhabitants. The jaws of death were opened to swallow them up; ruin had seized all their possessions; and those dear connections to which they might have looked for consolation in their sorrows, were for ever buried in the merciless abyss. All was ruin and desolation. Every countenance indicated the extremity of affliction and despair; and the whole country formed a wide scene of undescribable horror.

One of the most remarkable towns which was destroyed was Casal Nuova, where the princess Gerace Grimaldi, with more than 4000 of her subjects, perished in the same instant. An inhabitant happening to be on the summit of a neighbouring hill, at the moment of the shock, and looking earnestly back to the residence of his family, could see no other remains of it than a white cloud which proceeded from the ruins of the houses. At Bagnara, about 3000 persons were killed; and not fewer at Radicina and Palma. At Terra Nuova 4400 perished; and rather more at Semniari. The inhabitants of Scilla escaped from their houses on the celebrated rock of that name, and, with their prince, descended to a little harbour at the foot of the hill; but, in the course of the night, a stupendous wave, which is said to have been driven three miles over land, on its return swept away the unfortunate prince, with 2473 of his subjects. It is computed that not less than 40,000 persons perished by this earthquake.

EASEL-PIECES, a denomination given by painters to such pieces as are contained in frames, in contradistinction from those painted on ceilings, &c.

EASEMENT, in law, a privilege or convenience which one neighbour has of another, whether by charter or prescription, without profit: such are a way through his lands, a sink, or the like. These, in many cases, may be claimed.

EASING, in the sea language, signifies the slackening of a rope, or the like: thus, to ease the bow-line or sheet, is to let them go slacker; to ease the helm, is to

let the ship go more large, more before the wind, or more arboard.

EAST INDIA COMPANY, a corporation or "united company of merchants of England trading to the East Indies;" which name is given them in stat. 6 Anne, c. 17, s. 13. more explicitly, according to their charter and adjustment of their rights, by stat. 9 and 10 W. III. c. 44, s. 61. "trading into and from the East Indies, in the countries and ports of Asia and Africa, and into and from the islands, ports, havens, cities, creeks, towns, and places of Asia, Africa, and America, or any of them, beyond the Cape of Good Hope, to the straights of Magellan; where any trade or traffic of merchandize is or may be used and had, to and from every of them."

The temporary rights of the company consist of, 1st, the sole and exclusive trade with India, and other parts within the limits already described; so that no other of the king's subjects can go thither or trade there, but by permission of the company, or pursuant to the directions of stat. 33 Geo. III. c. 52. 2dly, They have the administration of the government and revenues of the territories in India, acquired by their conquests during their term in the exclusive trade, subject nevertheless to the various checks and restrictions contained in the several statutes, which vest that administration in them.

The rights in perpetuity are, to be a body corporate and politic, with perpetual succession; to purchase, acquire, and dispose at will of lands and tenements in Great Britain, so that the value therein do not exceed 10,000*l.* per annum; to make settlements to any extent within the limits of their exclusive trade; build forts and fortifications; appoint governors; erect courts of judicature; coin money; raise, train, and muster, forces at sea and land; repel wrongs and injuries; make reprisals on the invaders or disturbers of their peace; and continue to trade within the said limits, with a joint stock, for ever, although their exclusive right of trading shall be determined by parliament.

The only privileges they can be constitutionally deprived of, are those of trading to the exclusion of others, and of governing the countries, and of collecting and appropriating the revenues of India. For further particulars concerning the East India company: see stat. 9 and 10 W. c. 44. s. 69.; 6 Anne, c. 3.; 7 Geo. I. c. 5.; 25 Geo. II. c. 26.; 7 Geo. III. c. 47.; 12 Geo. III. c. 54.; 13 Geo. III. c. 63.; 17 Geo. III. c. 8.; 21 Geo. III. c. 70.; 24 Geo. III. c. 25.; and 33 Geo. III. c. 52.

For the history and commercial concerns of this establishment, see COMPANY.

EASTER, a festival of the Christian church, observed in memory of our Saviour's resurrection.

The Asiatic churches kept their Easter upon the same day the Jews observed their passover; and others on the first Sunday after the first full moon in the new year. This controversy was determined in the council of Nice, when it was ordained that Easter should be kept upon one and the same day, which should always be a Sunday in all Christian churches throughout the world. But though the Christian churches differed as to the time of celebrating Easter, yet they all agreed in showing particular respect and honour to this festival. On this day, prisoners and slaves were set free, and the poor liberally provided for. The eve or vigil of this festival was celebrated with more than ordinary pomp, which continued till midnight, it being a tradition of the church that our Saviour rose a little after midnight; but in the East, the vigil lasted till cock-crowing.

It was in conformity to the custom of the Jews, in celebrating their passover on the 14th day of the first month, that the primitive fathers ordered that the 14th day of the moon, from the calender new moon which immediately follows the 21st of March, at which time the vernal equinox happened upon that day, should be deemed the paschal full moon, and that the Sunday after should be Easter-day; and it is upon this account that our rubric has appointed it upon the first Sunday after the first full moon immediately following the 21st day of March. Whence it appears, that the true time for celebrating Easter, according to the intention of the council of Nice, was to be the first Sunday after the first full moon following the vernal equinox, or when the sun entered into the first point of Aries; and this was pope Gregory's principal view in reforming the calendar, to have Easter celebrated according to the intent of the council of Nice.

Having first found the epact and dominical letter, according to the method delivered under these articles, Easter-day may be found by the two following rules;

1. To find Easter-limit, or the day of the paschal full moon, counting from March 1 inclusive, the rule is this: add 6 to the epact, and if this sum exceeds 30, take 30 from it; then from 50 subtract this remainder, and what is left will be the limit; if the sum of the epact, added to 6, does not amount to 30, it must be subtracted from 50, and the remainder is the limit required; which is never to exceed 49, nor fall short of 21.

2. From the limit and dominical letter, to find Easter-day: add 4 to the dominical letter; subtract this sum from the limit, and the remainder from the next higher number which contains 7 without any remainder; lastly, add this remainder to the limit, and their sum will give the number of days from the first of March to Easter-day, both inclusive.

Thus, to find Easter-day for the year 1806, for instance. First find the epact 11, which added to 6 gives 17; and as this sum does not amount to 30, it must be subtracted from 50, and the remainder 33 is the limit. Then adding 4 to 5, the number of the dominical letter E, subtract this sum, viz. 9, from the limit 33, and the remainder 24 from 28, the next superior number that contains 7 a certain number of times without any remainder, and there remains 4; which being added to the limit 33, gives 37 for the number of days from the 1st of March to Easter-day, both inclusive: hence, allowing 31 for March, there remains the 6th April for Easter-day. Here follows the operation at length.

$11 + 6 = 17$

$50 - 17 = 33$ paschal limit.

Dominical letter $E = 5$

$4 + 5 = 9$, and $33 - 9 = 24$; and

$28 - 24 = 4$. Again,

$33 + 4 = 37$: from this subtract 31 for the number of days in March, and it is evident that Easter-day must fall on the 6th of April.

However, to save the trouble of calculation, we shall here give a table, by which Easter-day may be found by

inspection till the year 1900, according to the Gregorian or new style.

Golden Number.	Dominical Letters. A.	B.	C.	D.	E.	F.	G.
I.	April 16	17	18	19	20	14	18
II.	April 9	3	4	5	6	7	8
III.	March 26	27	28	29	23	24	25
IV.	April 16	17	11	12	13	14	15
V.	April 2	3	4	5	6	March 31	April 1
VI.	April 23	24	25	19	20	21	22
VII.	April 9	10	11	12	13	14	8
VIII.	April 2	3	March 28	29	30	31	April 1
IX.	April 16	17	18	19	20	21	22
X.	April 9	10	11	5	6	7	8
XI.	March 26	27	28	29	30	31	25
XII.	April 16	17	18	19	13	14	15
XIII.	April 2	3	4	5	6	7	8
XIV.	March 26	27	28	22	23	24	25
XV.	April 16	10	11	12	13	14	15
XVI.	April 2	3	4	5	March 30	31	April 1
XVII.	April 23	24	18	19	20	21	22
XVIII.	April 9	10	11	12	13	7	8
XIX.	April 2	March 27	28	29	30	31	April 1

In this table Easter-day will be found in the common angle of meeting of the given dominical letter and the golden number; the name of the month lying in a direct line with it, towards the left hand. Thus for the year 1806, the golden number is II, and the dominical letter is E, and in the line opposite to II and E will be found April 6th for Easter-day.

EDOMARIUS, in ecclesiastical writers, an officer formerly appointed weekly to superintend the performance of divine service in cathedrals, and prescribe the duties of each person attending in the choir, as to reading, singing, praying, &c.

EBENUS, the ebony-tree, a genus of the decandria order, in the diadelphia class of plants, and in the natural method ranking under the 32d order, papilionaceæ. The segments of the calyx are the length of the corolla, and the latter has scarcely any alæ. There is one rough seed. There are two species.

The cretica is a native of the island of Crete, and some others in the Archipelago. It rises with a shrubby stalk, three or four feet high, which puts out several side-branches with hoary leaves at each joint, composed of five narrow spear-shaped lobes, which join at their tails to the footstalk, and spread out like the fingers of a hand. The branches are terminated by thick spikes of large purple flowers. The plants may be propagated from seeds sown in the autumn. In this country the plants must be protected during the winter, as they are unable to bear the cold.

The pinnata is a biennial, a native of the Levant. These plants constitute the genus ebenus of botanists; but there is reason to think that the wood of this name is produced from several different trees. See the next article.

EBONY-WOOD is brought from the Indies, exceedingly hard and heavy, susceptible of a very fine polish, and on that account used in mosaic and inlaid works, toys, &c. There are many kinds of Ebony: the most usual among us are black, red, and green, and all of them the product of the island of Madagascar, where the natives call them indifferently *hazon mainthi*, black wood. The island of St. Maurice, belonging to the Dutch, likewise furnishes part of the ebonies used in Europe.

Authors and travellers give very different accounts of the tree that yields the black ebony. By some of their descriptions, it should be a sort of palm-tree; by others, a cytisus, &c. The most authentic of them is that of M. Flacourt, who resided many years in Madagascar as governor. He assures us that it grows very high and large, its bark being black, and its leaves resembling those of our myrtle, of a deep dusky-green colour. Tavernier assures us, that the islanders always take care to bury their trees, when cut down, to make them the blacker, and to prevent their splitting when wrought. F. Plumier mentions another black ebony-tree, discovered by him at St. Domingo, which he calls *spartium portulacæ foliis aculeatum ebeni materiæ*. Candia also bears a little shrub, known to the botanists under the name of ebenus cretica, above described.

Pliny and Dioscorides say, the best ebony comes from Ethiopia, and the worst from India; but Theophratus prefers that of India. Black ebony is much preferred to that of other colours. The best is a jet black, free of veins and rind, very massive, astringent, and of an acrid pungent taste. Its rind, infused in water, is said to be antiscorbutic, and to cure venereal disorders; whence Matthiolus took guiacum for a sort of ebony. It yields an agreeable perfume when laid on burning coals: when green, it readily takes fire from the abundance of its fat. If rubbed against a stone, it becomes brown. The Indians make statues of their gods, and sceptres for their princes, of this wood. It was first brought to Rome by Pompey, after he subdued Mithridates. It is now much less used among us than formerly; since the discovery of so many ways of giving other hard woods a black colour. As to the green ebony, besides Madagascar and St. Maurice, it likewise grows in the Antilles, and especially in the isle of Tobago. The tree that yields it is very bushy; its leaves are smooth, and of a fine green colour. Under its bark is a white substance about two inches thick; all beneath which, to the very heart, is a deep green, approaching towards a

black, though sometimes streaked with yellow veins. Its use is not confined to Mosaic work: it is likewise useful in dyeing, as yielding a fine green tincture. As to red ebony, called also grenadilla, we know little of it more than the name. The cabinet-makers, in-layers, &c. make pear-tree and other woods pass for ebony, by giving them the same black colour. This some do by a few washes of a strong decoction of galls, to which is added a small quantity of vitriolated iron.

EBIONITES, in church history, a sect of the first century so called from their leader Ebion. They held the same doctrines with the Nazarenes, united the ceremonies of the Mosaic institution with the precepts of the gospel, observed both the Jewish sabbath and Christian Sunday, and in celebrating the Eucharist, made use of unleavened bread. They abstained from the flesh of animals, and even from milk. In relation to Jesus Christ, some of them held that he was born, like other men, of Joseph and Mary, and acquired sanctification only by his good works. Others of them allowed, that he was born of a virgin, but denied that he was the word of God, or had any existence before his human generation. They said he was, indeed, the only true prophet, but yet a mere man, who by his virtue had arrived at being called Christ, and the Son of God. They also supposed that Christ and the devil were two principles, which God had opposed to each other. Of the New Testament they only received the gospel of St. Matthew, which they called the gospel according to the Hebrews.

EBONY. See Ebenus.

EBRBUHARITES, an order of Mahometan monks, so called from their founder Ebrbuhar. They made great professions of piety, and contempt of the world; but are accounted heretics by the rest of the Mahometans, because they believe themselves not obliged to go in pilgrimage to Mecca.

ECATESIA, in antiquity, an anniversary solemnity observed by the Stratonicensians in honour of Hecate. The Athenians likewise had a public entertainment or supper every new moon in honour of the same goddess. The supper was provided at the charge of the richer sort; and was no sooner brought to the accustomed place, than the poor people carried all off, giving out that Hecate had devoured it.

ECATOMBÆON, in chronology, the first month of the Athenian year. It consisted of 30 days, and began the first new moon after the summer solstice, and consequently answered to the latter part of our June and beginning of July. The Bœotians called it hippodromus, and the Macedonians lous. The word is a derivative from the Greek ἑκατόμβη, a hecatomb, because of the great number of hecatombs sacrificed in it.

ECHENEIS, the remora, in ichthyology, a genus belonging to the order of thoracici. The head is flat, naked, depressed, and marked with a number of transverse ridges; it has ten rays in the branchiostege membrane; and the body is naked. There are two species, viz.

1. The remora or sucking-fish, with a forked tail, and 18 striæ on the head. It is found in the Indian Ocean.

2. The muriates, with an undivided tail, and 16 striæ on the head. It is likewise a native of the Indian Ocean.

These fishes are often found adhering so strongly to the sides of sharks and other great fish, by means of the structure of the head, as to be got off with difficulty. This fish was believed by all the ancients to have most wonderful powers, and to be able, by adhering to the bottom, to arrest the motion of a ship in its fullest course; and in love affairs to deaden the warmest affections of both sexes.

ECHEVIN, scabinus, in the former French and Dutch polity, a magistrate elected by the inhabitants of a city or town, to take care of their common concerns, and the decoration and cleanliness of the city.

ECHINOPHORA, in botany, a genus of the digynia order, in the pentandria class of plants; and in the natural method ranking under the 45th order, umbellatæ. The male florets are lateral, with the central one hermaphrodite; there is one seed, sunk into an indurated involucrum. There are two species, herbaceous plants of the south of Europe.

ECHINOPS, a genus of the polygamia segregatæ order, in the syngenesia class of plants, and in the natural method ranking under the 49th order, compositæ. The calyx is uniflorous; the corolla tubulated and hermaphrodite; the receptacle bristly; the pappus indistinct. There are five species, annual and perennial plants, one of which is well known under the name of globe thistle.

ECHINORYNCHUS, a genus of the vermes intestina; body round, proboscis cylindrical, retractile, and crowned with crooked prickles. They are found fixed firmly to the viscera of various animals, generally the intestines; and often remain on the same spot during the whole life of the animal; they are mostly gregarious, and are easily distinguished from the tænia by their round inarticulate body. There are 48 species, infesting the mammalia, birds, reptiles, and fish.

ECHINUS, in zoology, the sea hedgehog, a genus of insects belonging to the order of vermes mollusca. The body is roundish, covered with a bony crust, and often beset with moveable prickles; and the mouth is below, and consists of five valves. 1. The esculentus, or eatable echinus, is of an hemispherical form, covered with sharp strong spines, above half an inch long; commonly of a violet colour; moveable; adherent to small tubercles, elegantly disposed in rows. These are their instruments of motion by which they change their place. This species is taken in dredging and often lodges in cavities of rocks just within low-water mark. They are eaten by the poor in many parts of England, and by the better sort abroad. In old times they were a favorite dish. They were dressed with vinegar, honied wine or mead, parsley or mint, and thought to agree with the stomach. They were the first dish in the famous supper of Lentulus, when he was made flamen martialis, or priest of Mars; by some of the concomitant dishes they seem to have been designed as a whet for the second course, to the holy personages, priests and vestals invited on that occasion. Many species of shell-fish made part of that entertainment. 2. The lacunosus, or oval echinus, is of an oval depressed form; on the top it is of a purple colour, marked with a quadrifoil, and the spaces between tuberculated in waved rows; the lower side studded, and

divided by two smooth spaces; length, four inches. When clothed, it is covered with short thickset bristles mixed with very long ones. There are 15 other species, all natives of the sea.

ECHITES, in botany, a genus of the monogynia order, in the pentandria class of plants, and in the natural method ranking under the 30th order, contortæ. There are two long and straight follicles; the seeds pappous; the corolla funnel-shaped, with the throat naked. There are 22 species, shrubs, chiefly of South America. The corymbosa, a species of this genus, is supposed to yield the elastic gum, according to Jacquin. See CAOUTCHOUC.

ECHIUM, *viper's buglóss*, a genus of the monogynia order, in the pentandria class of plants, and in the natural method ranking under the 41st order, asperifoliæ. The corolla is irregular, with the throat naked. There are 21 species, three of which are natives of Britain. None of them have any remarkable property, except that the flowers of one species (the vulgare) are very grateful to bees. It is a native of many parts of Britain. The stem is rough, with hairs and tubercles. The leaves are spear-shaped, and rough with hair. The flowers come out in lateral spikes. They are first red, afterwards blue, sometimes purple or white. Cows and sheep are not fond of this plant; horses and goats refuse it.

ECHO, a sound reflected, or reverberated from some body, and thence returned or repeated to the ear.

For an echo to be heard, the ear must be in the line of reflection; that the person who made the sound may hear the echo, it is necessary he should be in a perpendicular line to the place which reflects it; and for a multiple or tautological echo, it is necessary that there should be a number of walls and vaults, rocks and cavities, either placed behind or fronting each other. Those murmurs in the air, that are occasioned by the discharge of great guns, &c. are a kind of indefinite echoes, and are produced from the vaporous particles suspended in the atmosphere, which resist the modulations of sound, and reverberate them to the ear.

There can be no echo, unless the direct and reflex sounds follow one another at a sufficient distance of time; for if the reflex sound arrives at the ear before the impression of the direct sound ceases, the sound will not be doubled, but only rendered more intense. Now if we allow that nine or ten syllables can be pronounced in a second, in order to preserve the sounds articulate and distinct, there should be about the ninth part of a second between the times of their appulse to the ear; or, as sound flies about 1142 feet in a second, the said difference should be $\frac{1}{9}$ of 1142, or 127 feet; and therefore every syllable will be reflected to the ear at the distance of about 70 feet from the reflecting body; but as in the ordinary way of speaking, three or four syllables only are uttered in a second, the speaker, that he may have the echo returned as soon as they are expressed, should stand about 500 feet from the reflecting body, and so in proportion for any other number of syllables. Mersenne allows for a monosyllable the distance of 69 feet, Morton 90 feet; for a dissyllable 105 feet, a trissyllable 160 feet, a tetrasyllable 182 feet, and a pentasyllable 204 feet.

From what has been said, it follows, that echoes may be applied for measuring inaccessible distances. Thus, Mr. Denham, standing upon the banks of the Thames, opposite to Woolwich, observed that the echo of a single sound was reflected back from the houses in three seconds; consequently the sum of the direct and reflex rays must have been $1142 \times 3 = 3426$ feet, and the half of it 1713 feet, the breadth of the river in that place.

It also follows that the echoing body being removed farther off, it reflects more of the sound than when nearer, which is the reason why some echoes repeat but one syllable, or one word, and some many. Of these some are tonical, which only return a voice when modulated into some particular musical tone, and others polysyllabical. That fine echo in Woodstock-park, Dr. Plot assures us, in the day-time will return very distinctly 17 syllables, and in the night 20.

Echoing bodies may be so contrived and placed, as that reflecting the sound from one to the other, a multiple echo, or many echoes, shall arise. At Rosneath, near Glasgow, in Scotland, there is an echo that repeats a tune played with a trumpet three times completely and distinctly. At the sepulchre of Metella, wife of Crassus, there was an echo, which repeated what a man said five times. Authors mention a tower at Cyzicus, where the echo repeated seven times. There is an echo at Brussels that answers 15 times.

One of the finest echoes we read of is that mentioned by Barthius, in his notes on Statius's Thebais, lib. 6, ver. 30, which repeated the words a man uttered 17 times. This was on the banks of the Naha, between Coblentz and Bingen. And whereas, in common echoes, the repetition is not heard till some time after hearing the words spoken, or the notes sung; in this, the person who speaks or sings, is scarcely heard at all, but the repetition very clearly, and always in surprising varieties; the echo seeming sometimes to approach nearer, and sometimes farther off; sometimes the voice is heard very distinctly, and sometimes scarcely at all: one person hears only one voice, and another several; one hears the echo on the right, and the other on the left, &c.

Addison, and other travellers in Italy, mention an echo at Simonetti palace, near Milan, still more extraordinary, returning the sound 56 times. The echo is heard behind the house, which has two wings; the pistol is discharged from a window in one of these wings, the second is returned from a dead wall in the other wing, and heard from a window in the back-front.

Farther, a multiple echo may be made, by so placing the echoing bodies, at unequal distances, as that they may reflect all one way, and not one on the other; by which means, a manifold successive sound will be heard; one clap of the hands like many; one ha! like a laughter; one single word like many of the same tone and accent; and so one musical instrument like many of the same kind, imitating each other.

Lastly, echoing bodies may be so ordered, that from any one sound given, they shall produce many echoes, different both as to tone and intention: by which means a musical room may be so contrived, that not only one instrument playing in it shall seem many of the same sort and size, but even a concert of different ones; this may be contrived by placing certain echoing bodies so,

as that any note played, shall be returned by them in 3ds, 5ths, and 8ths. See PNEUMATICS.

ECHO is also used for the place where the repetition of the sound is produced or heard. This is either natural or artificial.

In echoes, the place where the speaker stands is called the centrum phonicum, and the object or place that returns the voice, the centrum phonocampticum.

ECHO, in architecture, a term applied to certain kinds of vaults and arches, most commonly of elliptical and parabolical figures, used to redouble sounds, and produce artificial echoes. We learn from Vitruvius, that in several parts of Greece and Italy, there were brazen vessels artfully ranged under the seats of the theatres, to render the sound of the actors' voices more clear, and make a kind of echo. A single arch or concavity can scarcely ever stop and reflect the sound; but if there is a convenient disposition between it, part of the sound that is propagated thither, being collected and reflected as before, will present another echo; or if there is another concavity opposed at a due distance to the former, the sound reflected from the one upon the other will be tossed back again upon this latter, &c.

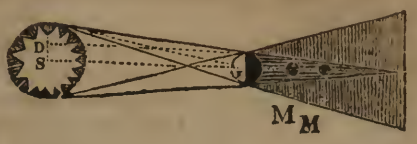
ECHO, in poetry, a kind of composition wherein the last words or syllables of each verse contain some meaning, which being repeated apart, answers to some question or other matter contained in the verse, as in this beautiful one from Virgil:

Crudelis mater magis, an puer improbus ille?
Improbus ille puer, crudelis tu quoque mater.

The elegance of an echo consists in giving a new sense to the last words, which reverberate, as it were, the motions of the mind, and by that means affect it with surprise and admiration.

ECHOMETER, among musicians, a kind of scale or rule, with several lines, serving to measure the duration and length of sounds, and to find their intervals and ratios.

ECLECTICS, acient philosophers, who, without attaching themselves to any particular sect, selected whatever appeared to them the best and most rational from each. Potamon of Alexandria was the first of the eclectics; he lived in the reigns of Augustus and Tiberius; and being tired with the scepticism of the pyrrhonians, he resolved upon a scheme that would allow him to believe something, but without being so implicit as to swallow any entire hypothesis.



ECLIPSE, in astronomy, the deprivation of the light of the sun, or of some heavenly body, by the interposition of another heavenly body between our sight and it. See ASTRONOMY.

ECLIPSE, *partial*, is when only a part of the luminary is eclipsed. And

ECLIPSE, *total*, is that in which the whole luminary is darkened.

ECLIPSE *of the moon*, is a privation of the light of the moon, occasioned by an interposition of the body of the earth directly between the sun and moon, and so intercepting the sun's rays that they cannot arrive at the moon, to illuminate her. Or, the obscuration of the moon may be considered as a section of the earth's conical shadow, by the moon passing through some part of it.

The manner of this eclipse is represented in this figure, where S is the sun, E the earth, and M or M the moon.

Lunar eclipses only happen at the time of full moon, because it is only then the earth is between the sun and moon; nor do they happen every full moon, because of the obliquity of the moon's path with respect to the sun's, but only in such full moons as happen either at the intersection of those two paths, called the moon's nodes, or very near them, viz. when the moon's latitude, or distance between the centres of the earth and moon, is less than the sum of the apparent semidiameters of the moon and the earth's shadow.

The chief circumstances in lunar eclipses are the following: 1. All lunar eclipses are universal, or visible in all parts of the earth which have the moon above their horizon; and are every where of the same magnitude, with the same beginning and end. 2. In all lunar eclipses, the eastern side is what first immerges and emerges again, i. e. the lefthand side of the moon as we look towards her, from the north; for the proper motion of the moon being swifter than that of the earth's shadow, the moon appproaches it from the west, overtakes and passes through it with the moon's east side foremost, leaving the shadow behind, or to the westward. 3. Total eclipses, and those of the longest duration, happen in the very nodes of the eclipse; because the section of the earth's shadow, then falling on the moon, is considerably larger than her disc. There may however be total eclipses within a small distance of the nodes; but their duration is the less as they are farther from it, till they become only partial ones, and at last none at all. 4. The moon, even in the middle of an eclipse, has usually a faint appearance of light, resembling tarnished copper, which Gassendus, Ricciolus, Kepler, &c. attribute to the light of the sun, refracted by the earth's atmosphere, and so transmitted thither. Lastly. She grows sensibly paler and dimmer, before entering into the real shadow, owing to a penumbra which surrounds that shadow to some distance.

ECLIPTA, a genus of the class and order syngenesia polygamia superflua. The recept. is chaffy; down none; corolets of the disk four-cleft. There are five species, herbaceous plants of the East and West Indies.

ECLIPTIC, in astronomy, a great circle of the sphere, supposed to be drawn through the middle of the zodiac, making an angle with the equinoctial of about 23° 30′, which is the sun's greatest declination; or, more strictly speaking, it is that path among the fixed stars that the earth appears to describe to an eye placed in the sun. See ASTRONOMY.

The ecliptic approaches nearer and nearer to a parallelism with the equator, at the rate of half a second in a year nearly, or from 50″ to 55″ in 100 years, as is deduced from ancient and modern observations compared together; and as the mean obliquity of the ecliptic was 23° 28′, about the end of the year 1788, or begin-

ning of 1789, by adding half a second for each preceding year, or subtracting the same for each following year, the mean obliquity will be found nearly for any year either before or since that period. The quantity however of this change is variously stated by different authors, from 50″ to 60″ or 70″ for each century or 100 years. Hipparchus, almost 2000 years since, observed the obliquity of the ecliptic, and found it about 23° 51′; and all succeding astronomers, to the present time, having observed the same, have found it always less and less, being now rather under 23° 28′; a difference of about 23′ in 1950 years; which gives a medium of 70″ in 100 years. There is great reason however to think that the diminution is variable.

This diminution of the obliquity of the ecliptic to the equator, according to Mr. Long, and some others, is chiefly owing to the unequal attraction of the sun and moon on the protuberant matter about the earth's equator. For if it is considered, say they, that the earth is not a perfect sphere, but an obliate spheroid, having its axis shorter than its equatorial diameter; and that the sun and moon are constantly acting obliquely upon the greater quantity of matter about the equator, drawing it in a manner towards a nearer and nearer coincidence with the ecliptic; it will not appear strange that these actions should gradually diminish the angle between the planes of these two circles. Nor is it less probable that the mutual attractions of all the planets should have a tendency to bring their orbits to a coindence; though this change is too small to become sensible in many ages.

It is now, however, well known, that this change in the obliquity of the ecliptic is wholly owing to the actions of the planets upon the earth, and especially the planets Venus and Jupiter. According to La Grange, who proceeds upon theory, the annual change of obliquity is variable, and has its limits; about 2000 years ago, he thinks it was after the rate of about 38″ in 100 years; that it is now, and will be for 400 years to come, 56″ per century; but 2000 years hence 49″ per century. According to Cassini, who computes from observations of the obliquity between the years 1739 and 1778, the annual change at present is 60″ or 1′ in 100 years. But according to La Lande, the diminution is at the rate of 88″ per century; while Dr. Maskelyne makes it only 50″ in the same time.

Beside the regular diminution of the obliquity of the ecliptic, at the rate of near 50 seconds in a century, or half a second a year, which arises from a change of the ecliptic itself, it is subject to two periodial inequalities, the one produced by the unequal force of the sun in causing the precession of the equinoxes, and the other depending on the nutation of the earth's axis. See the Explanation and Use of Dr. Maskelyne's Tables and Observations, pa. vi, where we are shown how to calculate those inequalities, and where he shows that, from his own observations, the mean obliquity of the ecliptic to the beginning of the year 1769. was 23° 28′ 9″.7.

To find the obliquity of the ecliptic, or the greatest declination of the sun; about the time of the summer solstice, observe very carefully the sun's zenith distance for several days together, then the difference between this distance and the latitude of the place, will be the obliquity sought, when the sun and equator are both on one side of the place of observation; but their sum will be the obliquity when they are on different sides of it. Or it may be found by observing the meridian altitude or zenith distance, of the sun's centre, on the days of the summer and winter solstice; then the difference of the two will be the distance between the tropics, the half of which will be the obliquity sought.

Table of the obliquity of the ecliptic at different periods.

Author's Names.	Years before Christ.	Obliquity.
Pytheas	324	23° 49′ 23″

As to the obliquity of the ecliptic, or the angle which its plane makes with that of the equinoctial, it is found to vary.

ECLIPTIC, in geography, a great circle on the terrestrial globe, not only answering to, but falling within the plane of the celestial ecliptic. See GLOBE.

ECLOGUE, in poetry, a kind of pastoral composition, or a small elegant poem, in a natural simple style. See POETRY.

ECPHORA, in architecture, commonly the distance between the extremity of a member or moulding, and the naked part of the column, or any other part it projects from.

ECSTATICI, in Grecian antiquity, a sort of diviners, who were cast into trances or ecstacies, in which they lay like dead men, or persons asleep, deprived of all sense or motion, but after some time, returning to themselves, they gave strange relations of what they had seen and heard.

ECTHESIS, in church-history, a confession of faith, in the form of an edict, published in the year 639, by the emperor Heraclius, with a view to pacify the troubles occasioned by the Eutychian heresy in the eastern church. The same prince revoked it, on being informed that pope Severinus had condemned it, as favouring the monothelites; declaring at the same time that Sergius, patriarch of Constantinople, was the author of it.

ECTHLIPSIS, among Latin grammarians, a figure of prosody, whereby the *m* at the end of a word, when the following word begins with a vowel, is elided, or cut off, together with the vowel preceding it, for the sake of the measure of the verse; thus they read mult' ille, for multum ille.

The reason of an ecthlipsis, which in Latin verse ought always to take place when the immediately following word begins with a vowel, is to prevent the harshness of an hiatus, or concourse of vowels.

ECTROPIUM, in surgery, is when the eye-lids are inverted, or retracted so as to show their internal or red surface, and cannot sufficiently cover the eye.

ECTYPE, among antiquarians, an impression of a medal, seal, or ring, or a figured copy of an inscription, or other ancient monument.

EDDY-TIDE, or EDDY-WATER, among seamen, is where the water runs back contrary to the tide; or that which hinders the free passage of the stream, and so causes it to return again.

EDGINGS, among gardeners, a series of small but durable plants, set round the edges or borders of flower-beds, &c.

The best and most durable plant for this use is box, which, if well planted, and rightly managed, will continue in strength and beauty for many years. The seasons for planting these are the autumn and very early in the spring; and the best species for this purpose is the dwarf Dutch box. The edgings of box are now only planted on the sides of borders next walls, and not, as was some time since the fashion, all round borders, or fruit-beds, in the middle of gardens, unless they have a gravel-walk between them, in which case it serves to keep the earth of the borders from washing down on the walks in hard rains, and fouling the gravel. Daisies, thrift, or sea-jely-flowers, and chamomile, are also used by some for this purpose; but they grow out of form, and require yearly transplanting.

EDICT, in matters of polity, an order or instrument, signed and sealed by a prince, to serve as a law to his subjects. We find frequent mention of the edicts of the prætor, the ordinances of that officer in the Roman law. In the French law, the edicts are of several kinds; some importing a new law or regulation; others, the erection of new officers, establishments of duties, rents, &c. and sometimes articles of pacification. In France edicts are much the same as a proclamation is with us, but with this difference, that the former have the authority of a law in themselves, from the power which issues them forth, whereas the latter are only declarations of a law, to which they refer, and have no power in themselves.

Edicts cannot exist in Britain, because the enacting of laws is lodged in the parliament, and not in the king.

Edicts are all sealed with green-wax to show that they are perpetual and irrevocable.

EEL, in ichthyology. See MURÆNA.

EELS, *microscopic*, those discovered by the microscope in pepper-water and other infusions of plants, &c. See MICROSCOPE.

EEL, *sea*, anguilla marina, a fish otherwise called conger, being a species of muræna, with the upper edge of the back-fin black. See MURÆNA.

EEL-*spear*, a cruel instrument with three or four jagged teeth, used for catching of eels; that with the four teeth is best, which they strike into the mud at the bottom of the river, and if it strikes against any eels, it never fails to bring them up.

EFFERVESCENCE. See CHEMISTRY.

EFFLUVIUM, in physiology, a term much used by philosophers and physicians, to express the minute particles which exhale from most, if not all, terrestrial bodies in form of insensible vapours.

EFT. See LACERTA.

EGG, *ovum*, in physiology, a body formed in certain females, in which is contained an embryo, or fœtus of the same species, under a cortical surface, or shell. The exterior part of an egg is the shell, which is in a hen, for instance, a white, thin, and friable cortex, including all the other parts. The shell becomes more brittle by being exposed to a dry heat. It is lined every where with a very thin, but pretty tough, membrane, which, dividing at, or very near, the obtuse end of the egg, forms a small bag, where only air is contained. In new-laid eggs, this folliculus appears very little, but becomes larger when the egg is kept. Within this membrane are contained the albumen, or white, and the vitellus, or yolk, each of which have their different virtues. The albumen is a cold, viscuous, white liquor in the egg, differing in consistence in its different parts. It is observed, that there are two distinct albumens, each of which are inclosed in its proper membrane; of these, one is very thin and liquid, and the other more dense and viscuous, and of a somewhat whiter colour, but in old and stale eggs, after some days incubation, inclining to a yellow. As this second albumen covers the yolk on all sides, so it is itself surrounded by the other external liquid. The albumen of a fecundated egg is as sweet and free from corruption, during all the time of incubation, as it is in new-laid eggs; as is also the vitellus. As the eggs of hens consist of two liquors separated one from another, and distinguished by two

branches of umbilical veins, one of which goes to the vitellus, and the other to the albumen, so it is very probable that they are of different natures, and consequently appointed for different purposes. When the vitellus grows warm with incubation, it becomes more tumid, and like melting wax, or fat; whence it takes up more space, for as the fœtus increases, the albumen insensibly wastes away, and condenses; the vitellus, on the contrary, seems to lose little or nothing of its bulk, when the fœtus is perfected, and only appears more liquid and humid when the abdomen of the fœtus begins to be formed. The chick in the egg is first nourished by the albumen and, when this is consumed, by the vitellus, as with milk. Not long before the exclusion of the chick, the whole yolk is taken into its abdomen; and the shell, at the obtuse end of the egg, frequently appears cracked, some time before the exclusion of the chick. The chick is sometimes observed to perforate the shell with its beak. After exclusion, the yolk is gradually wasted, being conveyed into the intestines by a small duct. See COMPARATIVE ANATOMY.

According to a chemical analysis of eggs, they consist of four parts; an oseous covering, called the shell, a membrane which covers the constituent parts of the egg; the white, or albumen, and the yolk. In 100 parts of the shell of hen's-eggs there are,

89.6 of carbonat of lime
5.7 of phosphat of lime
4.7 of animal matter

100.0

The white, or albumen, is nearly of the same nature as the serum of blood. See ALBUMEN.

The yolk contains a lymphatic substance, mixed with a certain quantity of mild oil. There is a considerable analogy between the eggs of animals and the seeds of vegetables. The yolk of eggs renders oils and resins soluble.

EGYPTIANS, *gipsies*, are a kind of commonwealth among themselves of wandering impostors and jugglers, who made their first appearance in Germany, about the beginning of the sixteenth century, and have since spread themselves over all Europe and Asia. By the laws of England, gipsies were formerly subject to imprisonment and forfeiture of goods, but they are now considered chiefly as rogues and vagabonds, and are described as such in the vagrant act. 4 Blac. 166.

EHRETIA, in botany, a genus of the monogynia order, in the pentandria class of plants, and in the natural method ranking under the 41st order, asperifoliæ. The fruit is a bilocular berry; the seeds solitary and bilocular; the stigma emarginated. There are five species, trees and shrubs of the West Indies.

EHRHARTA, a genus of the monogynia order, in the hexandria class of plants. The calyx is a two-valved, one-flowered glume; the corola is a double glume, each two-valved; the exterior one compressed, and scymitar-shaped, transversely wrinkled, and gashed at the base. There are six stamina, three on each side the pistil, in a parallel line. The stigma is simple, compressed, four-tufted, and torn at the top. There are five species; grasses of the Cape.

EJECTIONE CUSTODIÆ, a writ which lies against him who casts out the guardian from any land during the minority of the heir.

EJECTMENT. Any ejectment is a mixed action, by which a lessee for years, when ousted, may recover his term and damages; it is real in respect of the lands, but personal in respect of the damages. Since the disuse of real action, this mixed proceeding is become the common method of trying the title to lands or tenements. Rumm. on Ejectments.

The modern method of proceeding in ejectment, entirely depends on a string of legal fictions; no actual lease is made; no actual entry by the plaintiff; no actual ouster by the defendant; but all are merely ideal for the sole purpose of trying the title. To this end, a lease for a term of years is stated in the proceedings to have been made by him who claims title to the plaintiff, who is generally an ideal fictitious person, who has no existence, though it ought to be a real person to answer for the defendant's costs. In this proceeding, which is the declaration, (for there is no other process in this action) it is also stated, that the lessee, in consequence of the demise to him made, entered into the premises; and that the defendant, who is also now another ideal fictitious person, and who is called the casual ejector, afterwards entered thereon, and ousted the plaintiff; for which ouster the plaintiff brings this action. Under this declaration is written a notice, supposed to be written by this casual ejector, directed to the tenant in possession of the premises; in which notice the casual ejector informs the tenant of the action brought by the lessee, and assures him, that as he, the casual ejector, has no title at all to the premises, he shall make no defence, and therefore he advises the tenant to appear in court, at a certain time, and defend his own title, otherwise he, the casual ejector, will suffer judgment to be had against him, by which the actual tenant will inevitably be turned out of possession. 2 Cromp. Prac. 152.

The ancient way of proceeding was by actual sealing a lease on the premises, by the party in interest who was to try the titles; and this method is still in use in the following cases:

First, Where the house or thing for which ejectment is brought is empty. Secondly, When a corporation is lessor of the plaintiff, they must give a letter of attorney to some person to enter and seal a lease on the land; for a corporation cannot make an attorney or a bailiff except by deed, nor can they appear but by making a proper person their attorney by deed, therefore they cannot enter and demise upon the land as natural persons can. L. Raym. 135. Thirdly, When the several interests of the lessor of the plaintiff are not known, for in that case it is proper to seal a lease on the premises, lest they should fail in setting out in their declaration the several interests which each man possesses. Fourthly, Where the proceedings are in an inferior court, they must proceed by actually sealing a lease, because they cannot make rules confess lease, entry, and ouster, inasmuch as inferior courts have not authority to imprison for disobedience to their rules.

It is a general rule, that no person can in any case bring an ejectment, unless he has in himself at the time a right of entry; for although by the modern practice

the defendant is obliged by rule of court, to confess lease, entry, and ouster, yet that rule was only designed to expedite the trial of the plaintiff's right, and not to give him a right which he had not before; and therefore, when it happens that the person claiming title to the lands has no right of entry, he cannot maintain his action. 3 Black. 206.

The damages recovered in these actions, though formerly their only intent, are now usually (since the title has been considered as the principal question) very small and inadequate, amounting commonly to one shilling, or some other trivial sum. In order therefore to complete the remedy, when the possession has been long detained from him that has right, an action of trespass also lies, after a recover in ejectment, to recover the mesne profits which the tenant in possession had wrongfully received; which action may be brought in the name of either the nominal plaintiff in the ejectment, or his lessor, against the tenant in possession, whether he is made party to the ejectment, or suffers judgment to go by default.

EKEBERGIA, a genus of the class and order decandria monogynia. The calyx is four-parted; petals four; berry contains five oblong seeds. There is one species, a tree of the Cape.

ELÆAGNUS, *oleaster*, or *wild olive*, a genus of the monogynia order, in the tetrandria class of plants, and in the natural method ranking under the 16th order, calycifloræ. There is no corola; the calyx is campanulated, quadrifid, superior; the fruit is a plum below the campanulated calyx. There are nine species. The most remarkable are, 1. orientalis, or eastern broad-leaved olive, with a large fruit, is a native of the Levant and some parts of Germany. The leaves are about two inches long, and one and a half broad in the middle. They are placed alternate, and of a silver colour; at the foot-stalk of every leaf there comes out a pretty long sharp thorn, which are alternately longer; the flowers are small, the inside of the empalement is yellow, and they have a strong scent when fully open. 2. The angustifolia, without thorns, is that kind commonly preserved in the gardens of this country. The leaves are more than three inches long, and half an inch broad, and have a shining appearance like satin. The flowers come out at the footstalks of the leaves, sometimes singly, at other times two, and sometimes three, at the same place. The outside of the empalement is silvery and studded; the inside of a pale yellow, and having a very strong scent. The flowers appear in July, and are sometimes succeeded by fruit. 3. The latifolia, with oval leaves, is a native of Ceylon, and some other parts of India.

The two first may be propagated by laying down the young shoots in autumn. They will take root in one year; when they may be cut off from the old trees, and either transplanted into a nursery for two or three years to be trained up, or into places where they are to remain. The proper time for this is in the beginning of March, or early in the autumn. They should be placed where they may be screened from high winds, for they grow very freely, and are apt to be split by the wind if they are too much exposed. The third sort is too tender to endure the open air of this country; and therefore must be kept in a warm stove, except during a short time in the warmest part of the summer. From the flowers of these plants an aromatic and cordial water has been drawn, which is said to have been successfully used in putrid and pestilential fevers. The genus elæagnus is not to be confounded with the oleaster, or wild olive of Gerard, Parkinson and Ray. The last is only a particular species of olive, called by Tournefort and Caspar Bauhine olea sylvestris.

ELÆIS, a genus belonging to the natural order of palmæ. The male calyx is hexaphyllous; the corola sexfid; the stamina six: the female calyx is hexaphyllous; the corola hexapetalous; the stigma three; the fruit is a fibrous plum, with a three-valved nut or kernel. There is one species, from the fruit of which, resembling an olive in shape, the negroes extract the famous palm oil.

ELÆOCARPUS, a genus of the monogynia order, in the polyandria class of plants, and in the natural method ranking with those of which the order is doubtful. The corola is pentapetalous and lacerated; the calyx is pentaphyllous; and the fruit is a plum, with a wrinkled shell. There are six species, trees of the East Indies. One of them, the copalliferus, yields the resin so useful as a varnish, called gum copal.

ELÆODENDRUM, olive wood, a genus of the pentandria monogynia class and order. The corola is five-petalled; drupe ovate, with a two-celled nut. There are two species, trees of Africa.

ELAPHEBOLIUM, in Grecian antiquity, the ninth month of the Athenian year, answering to the latter part of February and beginning of March. It consisted of 30 days, and its name from the festival elaphebolia, kept in this month, in honour of Diana the huntress, on which occasion, a cake made in the form of a deer was offered to her.

ELASMIS, in natural history, a genus of tales, composed of small plates in form of spangles, and either single, and not farther fissile, or if complex, only fissile to a certain degree, and that in somewhat thick laminæ.

Of these tales there are several varieties, some with large and others with small spangles, which differ also in colour, and other peculiarities. See TALC.

ELASTICITY, or *elastic force*, that property of bodies with which they restore themselves to their former figure, after any external pressure; being the same with what is otherwise called springiness, very observable in a bent bow, steel springs, and the like.

There are in nature a variety of activities; in some of which the causes are rendered manifest by experimental inquiries; in others, and among these we may reckon elasticity, where no cause at all is discoverable by the senses.

A variety of experiments prove the existence of an elastic force. The separation of two bodies after impact, is a proof of elasticity. Metals, semi-metals, stones, gems, fossils, cartilages, most fluids, as air, and even water, exert an influence opposite to the direction of the force compressing them, and discover a tendency to return to their natural state: which tendency is in all of them imperfect, and less than the force impressed; but most perfect in glass, ivory, hardened steel, and cartilages.

Elasticity is increased by augmenting the density of a body: thus metals are rendered more elastic by being beaten by a hammer: and their elasticty, which was scarcely sensible before, by this process becomes very sensible. Steel is more elastic when tempered, and its density is increased in the ratio of 7809 to 7738.

Elasticity is sometimes increased by cold; thus the range of a cannon-ball is said to be greater when the cannon is cold, than when heated; and the string of a violin, or a steel lamina, is inflected, and also recovers its situation, with less force in hot than in cold weather.

Metal fibres, and thin steel laminæ, exhibit no elasticity, unless stretched to a certain degree, and inflected by a certain force; as appears from lax cords, which, if a little stretched and removed from their natural state, discover no tendency to return to it; and when the inflection of a fibre is very great, the influence of elasticity seems to be in some cases annihilated; as appears by the fibres of wood, which, inflected to a certain degree, remain quiescent, and have no tendency to recover their former situation. The limits where the elastic power begins, or where it terminates, are unknown.

Motion is supposed to be communicated or diffused, in elastic bodies, from the point of impact to the remote parts; and this supposition is grounded on the following experiments.

If two ivory balls are suspended, so that their centres are in one line. The surface of one of them, B, is fresh painted. By letting them touch each other gently, A receives a small point of paint upon its surface. Now by raising the ball A, so that it may impinge with some violence on B, it will be evident that the surface of each ball has been flattened by the blow; for there is on each a circular mark, shown by the paint struck off, and the other by the paint received; and, as the balls retain their spherical figure after the impact, it is clear that the parts of the surface not only lost, but recovered their figure.

Two glass balls may, with a proper degree of velocity, so impinge on each other, that the interior parts of the ball will be broken, though the exterior contiguous to the point of impact, be unbroken.

Suspend two ivory balls from the same point, by strings of the same length, and let the smaller ball A, impinge upon B, at rest, with a given velocity. A will be reflected always to the same height, and B will be impelled to the same height. But if either A or B is hollowed, and lead inserted in the centre or near to the posterior surface, neither ball, though the weight be the same, will ascend as high as before the insertion of the lead. The progressive motion of the parts from the point of impact is stopped by the insertion of the lead; and consequently, the force of restitution and the change of figure, is less than before it was inserted.

The motion diffused from the point of impact to the remote parts of an elastic body, is continued for some time, and diminishes gradually till it vanishes: and there seem to be two kinds of vibrations in the parts of an elastic body; one of which is quick, and called a tremor of its minute parts; and the other slower and longer, by which its figure is changed, and an impinging body repelled.

A stroke or friction upon the edge of a glass, communicates a tremulous motion to the parts of the glass, which is visibly communicated to the water it may contain. A reed or stick placed across the bottom of a large glass bell, will fall when the glass is struck, the stroke producing a change of figure. If you hold a piece of metal near the brim or lip of a bell, without touching it, and the bell is stricken by a hard body, you will see it touch the piece of metal, and will hear a succession of sounds gradually decaying. If the edge of the bell is pinched, and the fingers suddenly withdrawn, the same sound is heard, without producing any sensible motion towards the piece of metal, or displacing the reed across it.

Those laws according to which alterations are produced in the rest and motion of bodies upon their collision, are called the laws of communication of motion.

When one body strikes against another, if the line of direction of the impulse passes through the centre of gravity of both the bodies, the impulse is called full or direct, otherwise it is called an oblique impulse.

The relative velocity of two bodies, is that velocity with which they approach to, or recede from, each other; and is equal either to the difference of the velocities of bodies moving the same way, or to the sum of the velocities of bodies moving contrary ways; for, if one of the bodies was at rest, and the other moved towards it or from it, with the fore-mentioned difference or sum of velocities, the body in motion would approach to, or recede from, the body at rest, just as fast as the two moving bodies approached to, or receded from, each other.

If two bodies move in the same direction with equal velocities, they are relatively at rest.

When the impulse is direct, and the bodies are void of elasticity, the laws of the communication of motion are as follow:

(1.) In all cases, the velocities after the stroke are equal; for the impulse ceases when the impinging bodies are relatively at rest, and not before. (2.) If two bodies move the same way, and in the same right line, that which moves fastest will overtake the other, and the sum of their motions will be the same after the stroke as before: for, by the third law of motion, so much motion as the slowest body gains, the swiftest body loses. (3.) If two bodies move contrary ways, the sum of their motions after the stroke will be equal to the difference of their motions before the stroke; for, whilst the strongest motion destroys the weakest, it also loses an equal part of itself, the third law of motion. (4.) If the sum of two conspiring motions, or the difference of two contrary motions, be divided by the sum of the quantities of matter in both the moving bodies, the quotient will give their common velocity after the stroke. (5.) If the velocity after the stroke be multiplied into the quantity of matter in each body, the product will express the quantities of motion in each body, after the stroke. (6.) The difference between the quantities of motion in either of the moving bodies before and after the stroke, is equal to the quantity of the stroke.

Example 1. Let a ball of three ounces, moving with nine degrees of velocity, overtake another ball, of two ounces, moving with four degrees of velocity: then will the quantities of motion before the stroke be 27 and 8, the common velocity after the stroke will be 7, the quan-

tities of motion after the stroke will be 21 and 14, and the quantity of the stroke will be 6.

Example 2. Let the same balls move with the same velocities contrary ways; then with the quantities of motion before the stroke be as before; the common velocity after the stroke will be $3\frac{4}{5}$, the quantities of motion after the stroke will be $11\frac{2}{5}$, and $7\frac{1}{5}$, and the quantity of the stroke $15\frac{3}{5}$.

Wherefore, if two equal bodies move in contrary directions, with equal velocities, as soon as they strike, both motions will be destroyed. And if a body in motion strikes an equal body at rest, it will communicate half its velocity or half its motion. And if one moving body overtakes another moving body equal to the first, the common velocity after the stroke will be equal to half the difference of their velocities before the stroke. But if they move in contrary directions, the velocity after the stroke will be equal to half the sum of the velocities before the stroke. (7.) If a moving body strikes against an immoveable obstacle, after the stroke the whole will be destroyed, and the quantity of the stroke will be equal to the whole quantity of the motion. (8.) If the moving body gravitates towards the immoveable obstacle, as when a stone falls upon the earth, the quantity of the stroke is equal to the sum of the quantity of motion added to the weight of the moving body; for the weight remains upon the obstacle when the impulse is destroyed.

The sum of the motions of two bodies void of elasticity, may be less after the stroke than it was before, but it cannot be more. (9.) If a body moves after the stroke, the same way that it moved before, the difference of the velocities before and after the stroke will be equal to the velocity lost or gained. Thus, in the first example, the velocity lost is 2, and the velocity gained 3. (10.) If the direction of the motion after the stroke is contrary to the direction of the motion before the stroke, the sum of the velocities before and after the stroke will express the quantity of the velocity gained. Thus, in the second example, the velocity is $5\frac{1}{5}$, the velocity gained $7\frac{4}{5}$.

When the impulse is direct, and the bodies perfectly elastic, the laws of the communication of motion are different from the foregoing. For,

(1.) Upon the collision of two elastic bodies, the force of elasticity is equal to the force of compression; and the force of compression in each body is equal to the quantity of the stroke. (2.) The whole force of elasticity exerted at the restitution of both the springs, is double the quantity of the stroke; for it is the result of two forces in contrary directions, each of which is equal to the quantity of the stroke. Or if it may be conceived thus: the sum of the elasticities is equal to the sum of the quantities of the stroke in both bodies together; that is, to double the quantity of the stroke in each single body. (3.) The effect of the elasticity in each body, will be equal to the effect of the stroke, and in the same direction; for the two equal and contrary elasticities in the former case, are equivalent to action and reaction in the latter. (4.) Wherefore, to find the velocity of either body after the collision, first find the common velocity with which the bodies would move after the stroke, if they had been void of elasticity, and find also the velocity lost or gained; then subtract the velocity lost from the common velocity, or to the common velocity add the velocity gained; so shall the difference or sum be the velocity sought. But if the velocity lost be greater than the common velocity, then subtract the common velocity from the velocity lost, and the remainder will give the velocity sought in a contrary direction.

Thus, in the first example before stated, if we suppose the bodies to be elastic, the velocities after collision will be 5 and 10, and, consequently the quantities of motion will be 15 and 2.

In the second example, the velocities after collision will be $1\frac{2}{5}$ and $11\frac{3}{5}$, and the quantities of motion $4\frac{1}{5}$ and $23\frac{1}{5}$.

For a third example, let us suppose two bodies in proportion as three to two; the first at rest, and the second moving towards the first with 40 degrees of velocity: then will the quanties of motion before the stroke be 0 and 80, the common velocity after the stroke 16, the quantities of motion after the stroke 48 and 32, the the quantity of the stroke 48, the velocity gained 16, the velocity lost 24, the velocities after the restitution of the springs 32, and 8 in a contrary direction; the quantities of motion after collision 96 and 16.

In the first example, the sum of the motion before collision is equal to the sum of the motion after collision; in the second, it is greater; in the third, less.

Two elastic bodies always recede from each other after collision, and that with the same relative velocity with which they tended towards each other before collision. Thus the relative velocity before and after collision, is 5 in the first example, 13 in the second, and 40 in the third.

And in all cases, whether the impinging bodies are elastic or not, the sum of the motions in the same direction, and the difference of the motions in a contrary direction, are the same both before and after collision.

If two equal elastic bodies move towards each other with equal velocities, they will recede from each other after collision each with the same velocity. If one of them in motion strikes against the other at rest, it will communicate the whole velocity, and remain at rest itself. If one overtakes the other, they will interchange velocities, and continue to go on the same way as before. If they meet each other with different velocities, they will interchange velocities, and fly off from each other in contrary directions.

If an elastic body strikes upon an immoveable elastic obstacle, it will rebound with the same velocity that it came.

If one of the impinging bodies is hard, and the other elastic, the laws of the communication of motion are the same as if both the bodies were elastic; for the spring will give way, till the force of elasticity becomes equal to the force of compression, that is, double to the quantity of the stroke in each body; and the re-action of a hard body against double the quantity of elasticity, will produce the same effect as a single quantity of elasticity in each body, acting in contrary directions.

If the impulse be oblique, it must be resolved into two impulses, one direct, and the other parallel to the tangent at the point of collision. The effect of the direct impulse must be computed according to the laws before

mentioned: the parallel impulse will continue after the collision the same in all respects that it was before; nor will it produce any other effect, except by means of the friction to make the bodies revolve each about its own centre of gravity.

It often happens that the communication of motion is the indispensable means of obtaining some other effect; thus it is used to nail and flatten bodies; in these cases it is not sufficient, that the striking body has a certain quantity of motion, the mass or quantity of matter must be so proportioned with the velocity, as to produce the required effect, without splitting or destroying the body struck.

In architecture there are many occasions, where it is necessary to drive piles; if the mass which strikes the pile is small, it will not have force sufficient to drive it, and if it is moved with considerable velocity, it will split the head of the pile; a large mass must therefore be used, moving with less velocity. If small hammers and a great velocity are used to drive pivots of iron into large pieces of wood, the head of the pivot will yield, and yet not be driven into the wood; whereas the effect will be answered by using hammers of considerable weight, moving with less velocity.

Gold-beaters and other workmen who flatten metals, make use of heavy hammers, and move them slowly; if they used small hammers, and moved them swiftly, the parts of the metal would be broken and divided by the strokes.

To prevent the propagation of motion, and to deaden the blow, those that work in their chambers, and are obliged to use anvils, place the blocks that hold the anvil upon a roll of matting, or upon springs; without this precaution, great part of the force impressed by the hammer would be transmitted to the floor, and would create a shaking to the prejudice of the building.

The principles above laid down will assist in explaining the recoil of cannon, fusees, and other arms; for you may consider the gunpowder as a spring which unbends or expands itself in every direction, but which can only act efficaciously against the breech of the cannon and the ball.

The action of the powder is that of two equal forces against two unequal powers of resistance, the ball and the cannon; it may therefore be supposed, cæteris paribus, to impress them both with an equal quantity of motion, but with different degrees of velocity; that of the ball being as much greater as its mass is less than that of the cannon, &c.

The cannon, the musket, &c. especially if you take into the account the obstacles which retain them, are much more difficult to move than the ball with which they are charged; which, of course, receives from the inflamed powder a much greater degree of velocity.

There are other circumstances which contribute to augment the velocity of the ball, as the length of the piece, &c. which do not come probably before us. As to the recoil in general, supposing the quantity and quality of the powder the same, a gun recoils so much the more as the bullet makes more resistance either by its weight or the wadding.

A rocket flies upwards, because its lower part, which is fired, performs the office of a spring, which acts one way against the body of the rocket, and the other way against a volume of air; and as this spring is continually renewed by the successive inflammation of all the parts of the rocket, its motion is accelerated, first, because it is contained in the body itself, and is therefore continually adding to its velocity; and secondly, because the weight or resistance of the rocket is diminishing every instant by the dissipation of the parts as they burn away.

ELATE, a genus belonging to the natural order of palmæ. There is no male calyx; the corolla is tripetalous, with three stamina. There is no female calyx; the corolla is tripetalous, with one pistil; the fruit is an oval acuminated plum. There is one species, a native of the East Indies, which grows to the height of 14 feet. The natives chew the nut in the same manner as the areca or the leaf of the betel.

ELATER, in zoology, a genus of insects, belonging to the order of coleoptera. The antennæ are setaceous; and an elastic spring or spine projects from the hinder extremity of the breast or under side of the thorax. By means of this kind of spring, the animal, when turned upon its back, contrives to leap up into the air, and so turn itself. It varies in size; and when the insect is young and newly metamorphosed, its elytra are of a beautiful deep red; but in a few days they change to a much darker hue, and are nearly of a chesnut colour. In the state of larvæ it inhabits the trunks of decayed trees, and is there transformed. With the help of its wings it issues from its prison, flutters upon flowers, wanders over the fields, and conceals itself in thickets or under the bark of trees. There are 38 species.

ELATERIUM, a genus of the monandria order, in the monœcia class of plants; and in the natural method ranking under the 34th order, cucurbitaceæ. There is no calyx; the corolla is salver-shaped; the capsule inferior, unilocular, and bivalved. There are two species, natives of America.

ELATINE, a genus of the tetragynia order, in the octandria class of plants; and in the natural method ranking under the 15th order, inundatæ. The calyx is tetraphyllous; the petals four; the capsule quadrilocular, quadrivalved, and depressed. There are two species, annual aquatics of Europe.

ELCESAITES, in church-history, a sect who made their appearance in the reign of the emperor Trajan, and took their name from their leader Elcesai. The Elcesaites kept a mean between the Jews, Christians, and Pagans; they worshipped but one God, observed the Jewish sabbath, circumcision, and the other ceremonies of the law. They rejected the Pentateuch and the Prophets; nor had they more respect for the writings of the apostles, particularly those of St. Paul.

ELECTION, is where a person has by law two remedies, and is compelled to declare which he will abide by: thus a creditor, in case of bankruptcy, may either prove his debt under the commission, or proceed at law; but in this case he is compelled to make his election. Where also a person having obtained a judgment, and is entitled to execution, he may either take his remedy against the goods or the person, and he may choose either; but if he proceed against the person in the first instance, he cannot afterwards have recourse to the

goods; but if he takes the goods, and these should be found inadequate to his demand, he may afterwards take the body.

ELECTION OF BISHOPS. See BISHOPS.

ELECTION OF A CLERK OF STATUTES-MERCHANT, a writ that lies for the choice of a clerk assigned to take and make bonds, called statutes-merchant, and is granted out of the chancery upon suggestion made, that the clerk formerly assigned is gone to dwell in another place, or is hindered from following that business, or has not land sufficient to answer his transgression if he should deal amiss. F. N. B. 164.

ELECTION OF ECCLESIASTICAL PERSONS. If any person that has a voice in elections, takes any reward for an election in any church, college, school, &c. such election shall be void; and if any such societies resign their places to others for reward, they incur a forfeiture of double the sum; and the party giving, and the party taking it, are thereby rendered incapable of such place. 13 Eliz. c. 6. See BISHOPS.

ELECTION OF MEMBERS OF PARLIAMENT. Qualification of the candidates. No member shall sit or vote in either house of parliament unless he be 21 years of age. 4 Inst. 47.

They must not be aliens-born; they must not be any of the twelve judges, because they sit in the lord's house. But persons who have judicial places in the other courts, ecclesiastical or civil, are eligible. 4 Inst. 47. Nor of the clergy; the reason assigned for which is, that they might sit in the convocation. Nor persons attainted of treason or felony, for they are unfit to sit any where. Id.

By the 30 C. II. st. 2. c. 1. and 1 Geo. I. c. 13. in order to prevent papists from sitting in either house of parliament, no person shall sit or vote in either till he has, in the presence of the house, taken the oaths of allegiance, supremacy, and abjuration, &c.

Sheriffs of counties, and mayors and bailiffs of boroughs, are not eligible in their respective jurisdictions, as being returning officers; but a sheriff of one county may be chosen knight of another. 1 Black. 175.

By several statutes, no persons concerned in the management of any duties or taxes created since 1692, except the commissioners of the treasury; nor any of the officers following, viz. commissioners of prizes, transports, sick and wounded, wine licences, navy and victualling; secretaries or receivers of prizes; comptrollers of the army accounts; agents for regiments; governors of plantations; officers of Minorca or Gibraltar; officers of the excise and customs; clerks or deputies in the several offices of the treasury, exchequer, navy, victualling, admiralty, pay of the army or navy, secretaries of state, salt, stamps, appeals, wine licences, hackney-coaches, hawkers, and pedlars; nor any persons that hold any new office under the crown, created since 1705, are capable of being elected. 1 Black. 175.

But this shall not extend to, or exclude the treasurer or comptroller of the navy, secretary of the treasury, secretary to the chancellor of the exchequer, secretaries of the admiralty, under secretary of state, deputy paymaster of the army, or any person holding any office for life, or so long as he shall behave himself well in his office. 15 Geo. II. c. 22.

By the 6 Anne, c. 7. s. 26. if any member shall accept an office of profit under the crown, except an officer of the army or navy accepting a new commission, his election shall be void, but he shall be capable of being re-elected.

No person having a pension from the crown during pleasure, shall be capable of being elected. 6 Anne, c. 7. s. 25.

By the 22 Geo. III. c. 45. no contractor with the officers of government, or with any other persons for the service of the public, shall be capable of being elected, or of sitting in the house, as long as he holds any such contract, or derives any benefit from it. But this does not extend to contracts with corporations, or with companies, which then consisted of ten partners; or to any person to whom the interest of such a contract shall accrue by marriage or operation of law, for the first twelve months. And if any person disqualified by such a contract shall sit in the house, he shall forfeit 500*l.* for every day; and if any person who engages in a contract with government admits any member of parliament to a share of it, he shall forfeit 500*l.* to the prosecutor.

No person shall be capable to sit or vote in the house of commons for a county, unless he has an estate, freehold or copyhold, for his life, or some greater estate, of the clear yearly value of 600*l.* nor for a city or borough, unless he has a like estate of 300*l.* and any other candidate, or two electors, may require him to make oath thereof at the time of election, or before the day of the meeting of parliament; and before he shall vote in the house of commons, he shall deliver in an account of his qualification, and the value thereof under his hand, and make oath of the truth of the same. But this shall not extend to the eldest son or heir apparent of a peer, or of any person qualified to serve as knight of a shire, nor to the members of the two universities. 9 Anne, c. 5. 33 Geo. II. c. 20.

Qualification of electors. No person shall be admitted to vote under the age of twenty-one years. This extends to all sorts of members, as well for boroughs as counties. 7 & 8 W. c. 25.

Every elector of a knight of a shire, shall have freehold to the value of 40*s.* a year within the county, which is to be clear of all charges and deductions, except parliamentary and parochial taxes. 1 Black. 172.

No person shall vote in right of any freehold, granted to him fraudulently, to qualify him to vote, and every person who shall prepare or execute such conveyance, or give his vote under it, shall forfeit 40*l.* 10 Anne, c. 23.

No person shall vote for a knight of the shire without having been in the actual possession of the estate for which he votes, or in the receipt of the rents or profits thereof to his own use, above twelve calendar months, unless it come to him by descent, marriage, marriage-settlement, devise, or promotion to a benefice or office. 18 Geo. II. c. 1.

No person convicted of perjury shall be capable of voting at an election.

No person shall vote in respect of an annuity or rent-charge, unless registered with the clerk of the peace twelve calendar months before. Such annuity or rent-charge issuing out of a freehold estate.

No person shall vote for a knight of a shire, in respect of messuages, lands, or tenements, which have not

been charged to the land-tax six calendar months before. 20 Geo. III. c. 17.

No person shall vote for any estate holden by copy of court-roll. 31 Geo. II. c. 14.

In mortgaged, or trust-estates, the mortgager, cestuy que trust, shall vote, and not the trustee or mortgagee, unless they be in actual possession.

All conveyances to multiply voices, or to sport votes, shall be void; and no more than one voice shall be admitted for one and the same house or tenement.

The right of elections in boroughs is various, depending entirely on the several charters, customs, and constitutions of the respective places: but by 2 Geo. II. c. 24, this right of voting for the future shall be allowed according to the last determination of the house of commons concerning it. And no person, claiming to vote in right of his being a freeman of a corporation (other than such as claim by birth, marriage, or servitude), shall be allowed, unless he has been admitted to his freedom twelve calendar months before. 3 Geo. III. c. 15.

Of election. As it is essential to the very being of parliaments that election should be absolutely free, all undue influence whatever upon the electors, is illegal, and strongly prohibited. As soon, therefore, as the time and place of election within counties or boroughs are fixed, all soldiers quartered in the place are to remove, at least one day before the election, to the distance of two miles or more, and not to return till one day after the poll be ended, except in the liberty of Westminster, or other residence of the royal family, in respect to his majesty's guards, and in fortified places. 8 Geo. II. c. 30.

By the 7 and 8 W. c. 4. to prevent bribery and corruption, no candidate, after teste of the writ of summons, or after a place becomes vacant in parliament time, shall, by himself, or by any other ways or means on his behalf, or at his charge, before his election, directly, or indirectly, give, or promise to give, to any elector any money, meat, drink, provision, present, reward, or entertainment, to, or for, any such elector in particular; or to any county, city, town, borough, port, or place in general, in order to his being elected, on pain of being incapacitated.

To guard still more against gross and flagrant acts of bribery, it is enacted by 2 Geo. II. c. 24, explained and enlarged by 9 Geo. II. c. 38. and 16 Geo. III. c. 11. that if any money, gift, office, employment, or reward, be given, or promised to be given, to any voter, at any time, in order to influence him to give or withhold his vote, as well he that takes, as he that offers such a bribe, forfeits 500*l.* and is for ever disabled from voting and holding any office in any corporation, unless before conviction he will discover some other offender of the same kind, and then he is indemnified for his own offence.

If the election shall not be determined upon view with the consent of the freeholders there present, but a poll shall be demanded, the same shall commence on the day on which such demand is made, or on the next day at farthest, (if it be not Sunday, and then on the day after) and shall be proceeded in from day to day (Sundays excepted) until it be finished, and shall not continue more than fifteen days (Sundays excepted) and the poll shall be kept open seven hours at least each day, between eight in the morning and eight in the evening. 25 Geo. III. c. 84. The sheriff shall allow a cheque-book for every poll-book for each candidate, to be kept by their inspectors at the place of taking the poll. 19 Geo. II. c. 28.

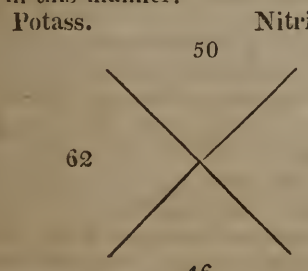
By the 34 Geo. III. c. 73. in order to expedite the business at elections, the returning officers are enabled, on request of the candidates, to appoint persons to administer to voters the oaths of allegiance, supremacy, the declaration of fidelity, the oath of abjuration, and the declaration or affirmation of the effect thereof, previously to their coming to vote; and to grant the voters certificates of their having taken the said oath, without which certificate they shall not be permitted to vote, if they are required to take the oaths.

And every freeholder, before he shall be admitted to poll for a knight of the shire, shall, if required by a candidate, or any elector, make oath of his qualification to vote, in which case the sheriff and clerks shall enter the place of his freehold, and the place of his abode, as he shall disclose the same at the time of giving his vote, and shall enter jurat against the name of every such voter who shall have taken the oath. 10 Anne, c. 23. s. 5.

Of the return. After the election, the names of the persons chosen shall be written in an indenture, under the seals of the electors, and tacked to the writ.

The election being closed, the returning officer in boroughs returns his precept to the sheriff, with the persons elected by the majority. And the sheriff returns the whole, together with the writ for the county, and the names of the knights elected thereupon, to the clerk of the crown in chancery, before the day of meeting, if it is a new parliament; or within fourteen days after the election, if it is an occasional vacancy; and this under the penalty of 500*l.* If the sheriff does not return such knights only as are duly elected, he forfeits by stat. H. VI. 100*l.* and the returning officer of a borough, for a like false return 40*l.* and by the late statutes they are liable to an action at the suit of the party duly elected, and to pay double damages, and the like remedy shall be against an officer making a double return. 1 Black. 180.

If two or more sets of electors make each a return of a different member (which is called a double election), that return only which the returning officer to whom the sheriff's precept was directed, has signed and sealed, is good; and the members by him returned shall sit until displaced on petition. Sim. 184.



On petition to the house of commons, complaining of an undue election, forty-nine members shall be chosen by ballot, out of whom each party shall alternately strike out one, till they are reduced to thirteen, who, together with two more, of whom each party shall nominate one, shall be a select committee for determining such controverted election. 10 and 11 Geo. III. c. 16.

ELECTION, in numbers, is with regard to combinations, the different ways of taking any number of quantities given: thus, the quantities *a b c* may be taken different ways, as *a b c*, or *a b*, *a c*, and *a*, *b*, *c*.

ELECTIVE attraction, in chemistry. The union of heterogeneous substances is effected in many instances

by elective attraction, *i. e.* a substance quits another with which it was before combined, to unite with a third, to which it is then said to have a superior affinity. Thus, when potass is added to sulphat of magnesia, in water, the sulphuric acid seizes the potass by its superior affinity, and the magnesia is *precipitated.* This is *simple affinity:* but if the potass is added in union with carbonic acid, the latter will seize the magnesia at the moment of its disengagement, forming carbonat of magnesia; and the sulphuric acid having combined with the potass, forming sulphate of potass, we have a case of double affinity. When several bodies are mixed, decompositions and new combinations often take place, which would not have been produced had the bodies been presented in a separate state. If for instance, into a solution of sulphat of ammonia there is poured nitric acid, no decomposition is produced, because the sulphuric acid has a stronger affinity for ammonia than nitric acid has. But if nitrat of potass is poured in, we obtain by evaporation two new bodies, sulphat of potass and nitrat of ammonia. Such cases of decomposition were called by Bergman cases of double elective attraction; a name which is exceedingly proper when there are only four bodies concerned. But as there are often more than four, it is necessary, as Mr. Morveau observed, to employ some more comprehensive term. The phrase compound affinity may be employed with propriety, comprehending under the term all cases where more than three bodies are present, and produce combinations which would not have been formed without their united action. In these cases the affinity of all the various bodies for each other acts; and the resulting combination has been supposed to be produced by the action of those affinities which are strongest.

The manner in which these combinations and decompositions take place, was thus explained by Dr. Black. Let the affinity between potass and sulphuric acid be = 62; that between nitric acid and amonia = 38; that between the same acid and potass = 50; and that between the sulphuric acid and ammonia = 46. Now, let us suppose that all these forces are placed so as to draw the ends of two cylinders crossing one another, and fixed in the middle in this manner:

It is evident that as 62 and 38 = 100 are greater than 50 + 46 = 96, they would overcome the other forces and shut the cylinders. Just so the affinity between ammonia and nitric acid, together with that between sulphuric acid and potass, overcomes the affinity between ammonia and sulphuric acid, and that between nitric acid and potass, and produces new combinations.

It has been supposed that in all cases of compound affinity, there are two kinds of affinities to be considered: 1st. Those affinities which tend to preserve the old compound, these Mr. Kirwan has called quiescent affinities; and those which tend to destroy them, which he has called divellent affinities.

Thus, in the instance above given, the affinity between ammonia and sulphuric acid, and that between nitric acid and potass, are quiescent affinities, which endeavour to preserve the old compound; and if they are strongest, it is evident that no new compound can take place. On the contrary, the affinity between potass and sulphuric acid, and that between nitric acid and ammonia, are divellent affinities; and as they are in this case strongest, they actually destroy the former combinations and form new ones.

It has been supposed that when two of those salts which mutually decompose each other are mixed together, the decomposition instantly takes place in consequence of the force of affinities alone, independant of the proportions of the ingredients.

Thus when sulphat of potass and nitrat of lime are mixed together, it was supposed that the sulphuric acid, if present in sufficient quantity, combines with the whole of the lime, and disengages the nitric acid and the potass, which also combine till the least abundant of the two is saturated. But if this was the case, some of the four ingredients must be left disengaged, as the proportions of the ingredients of the salts formed by the four ingredients are not such as to saturate each other. According to Mr. Kirwan's experiments, the proportions of acid and alkali in the four following salts are as under:

Sulphat of potass	Acid	100
	Potass	121.48
Sulphat of lime	Acid	100
	Lime	70
Nitrat of potass	Acid	100
	Potass	117.7
Nitrat of lime	Acid	100
	Lime	55.7

Now let sulphat of potass and nitrat of lime be mixed together; let the quantity of sulphat of potass be such, that the acid contained in it amounts to 100; and let a more than sufficient quantity of nitrat of lime be added, to saturate the sulphuric acid with lime. It is evident that for that purpose 70 of lime must be present; and the quantity of nitric acid combined with these 70 must be 123.8. This quantity would require for saturation 145.7 of potass, but there are only 121.48 in the mixture; consequently there ought to exist in the mixture, after the mutual decomposition of the salts, a quantity of nitric acid in a state of liberty. But the fact is, that no such excess of acid exists in the mixture. This is a sufficient proof that the decomposition does not take place in the manner that has been supposed. It may be said, indeed, that the composition of these salts may not be sufficiently known to warrant reasoning from it. But be the proportion of the ingredients what it may, still if the decomposition was absolute, as has been supposed, when mixed in any proportion whatever, except in one, some of the ingredients ought to remain disengaged: but as this does not happen either in this case or in any

other, we have a right to conclude that the decomposition is not what it has been considered.

2. When two saline solutions are mixed together, either no apparent change takes place, or a precipitate is formed. Let us consider each of these cases.

When no precipitation takes place, the two salts no doubt combine together, and form a compound consisting of the two acids and their bases; and the degree of saturation must be the same as before mixture, because the proportions and the affinities must continue the same. Hence the reason that in these cases there are never any indications of any of the ingredients being disengaged from the others. Hence also the reason that when two salts are dissolved in water, they increase the solubility of each other, their mutual affinity serving as an additional counterbalance to the cohesion of each. Thus Vauquelin has shown that saturated solutions of sulphat of lime, alum, and sulphat of potass, are capable of dissolving a greater proportion of common salt than pure water is.

3. When two salts may be mixed together without any precipitation taking place, it is a proof that all the salts capable of being formed by the component parts of each are soluble. Hence the alkaline salts very rarely occasion a precipitate when mixed together, nor the earthy salts when the acid combined in each is such as to form soluble salts with all the earthy bases, as nitric acid, muriatic acid. On the other hand, when a precipitation takes place, some two of the ingredients form an insoluble compound; consequently we can easily determine beforehand whether or not a precipitate will take place. It is from this precipitation chiefly that double decompositions have been determined. It is obvious that they are occasioned not by the superiority of the affinity of the ingredients which precipitate, but by the strong tendency which these ingredients have to cohere together; the consequence of which tendency is, the exclusion of the other component parts. and the precipitation of the masses as they form. It may be considered, then, as a general law, that "whenever a salt is insoluble, the two ingredients which compose it, whenever they meet in a solution, precipitate in combination." For this general law we are indebted to Mr. Berthollet.

Thus barytes forms an insoluble compound with sulphuric acid, phosphoric acid, oxalic acid, tartarous acid, &c. Consequently when a salt, whose base is that earth, is mixed with a salt containing any of these acids, a precipitation takes place consisting of the barytes combined with the acid. Salts of lime form a precipitate with oxalats, tartrites, citrats, phosphats, fluats, and sometimes with sulphats. The alkaline carbonats occasion a precipitate in all the earthy salts, because all the earthy carbonats are insoluble. Asetite of lead occasions a precipitate in sulphats, muriats, phosphats, mucitates, &c. Nitrat of silver in the muriats. But it would be endless to run over all the precipitates occasioned by the mixture of salts; every person may ascertain them merely by observing what salts are insoluble.

It ought to be observed, however, that the precipitation takes place, not because the salts are insoluble in water, but because they are insoluble in the particular solution in which the precipitate appears. Now if this solution happens to be capable of dissolving any particular salt, that salt will not precipitate, even though it is insoluble in water. Hence the reason why precipitates so often disappear when there is present in the solution an excess of acid, of alkali, &c.

This law has been still further generalized by Berthollet. When different salts are mixed together, they separate either spontaneously, or on evaporation, according to the order of their solubility. Those which are insoluble precipitate immediately on the mixture, and those which are least soluble crystallize first when the solution is evaporated. Potass forms with sulphuric acid a salt much less soluble than sulphat of soda. Hence the reason why it has been supposed to have a stronger affinity for sulphuric acid, and by analogy for acids in general, than soda: for if sulphat of soda is mixed with the greater number of the salts of potass, sulphat of potass is obtained by evaporation.

But in case where two salts are mixed together, the resulting salts are much influenced by the proportions of the ingredients. The same salts are not obtained if the ingredients are mixed in one proportion, that would be obtained if they were mixed in another proportion. This will appear evidently from the following experiments of Berthollet.

Salts Mixed.	Proportions.	Precipitate.	First Evaporation.	Second Evaporation.	Mother Water.
Nitrat of lime Sulphat of potass	1 1	Sulphat of lime	Nitrat of potass Sulphat of lime	A little sulphat of potass	Little
Ditto	1 2	Ditto	Sulphat of potass Sulphat of lime	Nitrat of potass Sulphat of potass Sulphat of lime	Very little
Ditto	2 1	Ditto	Sulphat of lime Nitrat of potass	Nitrat of potass A very little sulphat of lime	Abundant
Sulphat of soda Nitrat of lime	1 1	Sulphat of lime	Nitrat of soda	Nitrat of soda	Abundant
Ditto	2 1	Ditto	Ditto	Ditto	Abundant

Salts Mixed.	Proportions.	First Evaporation.	Second Evaporation.	Third Evaporation.	Mother Water.
Sulphat of soda Nitrat of potass	1 1	Sulphat of potass A little nitrate of potass	Nitrat of potass Some sulphat of potass	Nitrat of soda Some nitrat of potass	Considerable
Ditto	2 1	Sulphat of potass	Sulphat of potass Some nitrat of potass	Sulphat of potass Nitrat of potass Nitrat of soda	Considerable
Nitrat of potass Muriat of lime	1 1	Nitrat of potass	Muriat of potass Some nitrat of do.		Abundant
Ditto	1 2	Muriat of potass			Abundant
Muriat of potass Nitrat of lime	1 1	Nitrat of potass Some muriat of do.	Muriat of potass Some nitrat of do.		Abundant
Sulphat of potass Muriat of magnes.	1 1	Sulphat of potass	Sulphat of potass Muriat of do. Sulph. of pot. & mag.	Muriat of potass Sulph. of magnesia	Considerable
Ditto	1 2	Ditto	Muriat of potass Sulphat of potass & magnesia	Ditto	Ditto

The mother-water, or the liquid which remains when mixtures of salts are separated by crystallization, alaways contains several salts, or rather their component parts, which are prevented from crystallization by their mutual action on each other. Hence the quantity of this mother-water is always the greater, the more soluble the salts are, that is to say, the less disposition they have to crystallize.

ELECTOR, a person who has a right to elect or choose another to an office, honour, &c. Elector is particularly, and by way of eminence, applied to those princes of Germany in whom lies the right of electing the emperor; being all sovereign princes, and the principal members of the empire. The electoral college, consisting of all the electors of the empire, is the most illustrious and august body in Europe. Bellarmine and Baronius attribute the institution of it to pope Gregory V. and the emperor Otho III. in the tenth century; of which opinion are the generality of historians, and particularly the canonists: however, the number of electors was unsettled, at least till the thirteenth century. In 1356 Charles IV. by the golden bull, fixed the number of electors at seven: three ecclesiastics, viz. the archbishops of Mentz, Treves, and Cologne; and four seculars, viz. the king of Bohemia, count palatine of the Rhine, duke of Saxony, and marquis of Brandenburg. In 1648, this order was changed, the duke of Bavaria being put in the place of the count palatine, who, having accepted the crown of Bohemia, was out-lawed by the emperor; but being at length restored, an eighth electorate was erected for the duke of Bavaria. In 1692, a ninth electorate was created by the emperor Leopold, in favour of the duke of Hanover, of the house of Brunswic Lunenburg.

There are now, or at least were a short time since, ten electors, viz. the king or elector of Bohemia; the elector of Bavaria, now a king also; the elector of Saxony; the elector of Brandenburg (king of Prussia); the elector of Hanover, at this moment, by an usurped authority, king of Prussia also; the elector arch-chancellor of the empire, whose residence is at Ratisbon; the elector of Saltsburgh; the elector of Baden; the elector of Wurtemburgh, and the elector of Hesse.

ELECTRICITY, is a term used to denote the operations of a very subtile fluid, in most cases invisible, but which sometimes becomes the object of our senses, proving itself to be one of the principal agents employed in producing the phenomena of nature.

History of discoveries relative to electricity.

The attractive power which amber and other electric bodies acquire by friction, was long known to philosophers; and it is almost unnecessary to remark, that this branch of science derives its name from ελεκτρον (electron), the Greek word for amber. The other electric properties were slowly discovered. Mr. Boyle was the first who had a glimpse of the electric light; as he remarked, after rubbing some diamonds in order to give them the power of attraction, that they afforded light in the dark.

Otto Cuericke, burgomaster of Magdeburg, made an electric globe of sulphur; and by whirling it about in a wooden frame, and rubbing it at the same time with his hand, he performed various electrical experiments. He added to the stock of knowledge the discovery that a body once attracted by an excited electric was repelled by it, and not attracted again till it had touched some other body. Thus he was able to keep a feather suspended in the air over his globe of sulphur; but he observed, that if he drove it near a linen thread, or the flame of a candle, it instantly recovered its propensity for approaching the globe again. The hissing noise, and the gleaming light, which his globe afforded, both attracted his notice.

These circumstances were, however, afterwards accurately remarked by Dr. Wall: who, by rubbing amber upon a woollen substance in the dark, found also that light was produced in considerable quantities, accompanied with a crackling noise; and what is still more extra-

ordinary, he adds, "this light and crackling seems in some degree to represent thunder and lightning."

Mr. Hawksbee first observed the great electric power of glass. He constructed a wooden machine, which enabled him conveniently to put a glass globe in motion. He confirmed all the experiments of Dr. Wall. He observed, that the light emitted by the friction of electric bodies, besides the crackling noise, was accompanied by an acute sense of feeling when applied to his hand. He says that all the powers of electricity were improved by warmth, and diminished by moisture.

Hitherto the distinction between those bodies which are capable of being excited to electricity and those which are only capable of receiving it from the others, appears scarcely to have been suspected. About the year 1729, this great discovery was made by Mr. Grey, a pensioner of the Charter-house. After some fruitless attempts to make metals attractive by beating, rubbing, and hammering, he conceived a suspicion, that as a glass tube, when rubbed in the dark, communicates its light to various bodies, it might possibly at the same time communicate its power of attraction to them. In order to put this to the trial, he provided himself with a tube three feet five inches long, and near an inch and one-fifth in diameter: the ends of the tube were stopped by cork; and he found that when the tube was excited, a down feather was attracted as powerfully by the cork as by the tube itself. To convince himself more completely, he procured a small ivory ball, which he fixed at first to a stick of fir four inches long, which was thrust into the cork, and found that it attracted and repelled the feather even with more vigour than the cork itself. He afterwards fixed the ball upon long sticks, and upon pieces of brass and iron wire, with the same success: and lastly, attached it to a piece of long packthread, and hung it from a high balcony, in which state he found that by rubbing the tube the ball was constantly enabled to attract light bodies in the court below.

His next attempt was to ascertain whether this power could be conveyed horizontally as well as perpendicularly: with this view he fixed a cord to a nail which was in one of the beams of the ceiling, and making a loop at that end which hung down, he inserted his packthread, with the ball which was at the end of it, through the loop of the cord, and retired with the tube to the other end of the room; but in this state he found that his ball had totally lost the power of attraction, Upon mentioning his experiments to a friend, it was suggested, that the cord which he had used to support his packthread might be so coarse as to intercept the electric power, and they accordingly attempted to remedy this evil by employing a silk string, which was much stronger in proportion to its size than a hempen cord. With this apparatus the experiment succeeded far beyond their expectations. Encouraged by this success, and attributing it wholly to the fineness of the silk, they proceeded to support the packthread to which the ball was attached by very fine brass and iron wire; but, to their utter astonishment, found the effect exactly the same as when they used the hempen cord; the electrical virtue utterly passed away; while, on the other hand, when the packthread was supported by a silken cord, they were able to convey the electric virtue 765 feet.

It was evident, therefore, that these effects depended upon some peculiar quality in the silk, which prevented it from conducting away the electrical power, as the hempen cord and the wire had done. This, probably, immediately led to the discovery of other non-conducting bodies; and hair, rosin, glass, &c. were presently made use of to insulate the bodies which were electrified. The next obvious improvement was to electrify separate bodies, by placing them upon non-conductors; and in this manner Mr. Grey and his friend Mr. Wheeler electrified a large map, a table-cloth, &c. &c. In the latter part of the same summer, Mr. Grey found that he could electrify a rod as well as a packthread, without inserting any part into his excited tube, and that it only required to be placed nearly in contact with the apparatus.

Mr. Grey proceeded to try the effects of electricity upon animal bodies. He suspended a boy on hair lines in a horizontal position; and bringing the excited tube near his feet, he found that leaf-brass was attracted very vigorously by the head of the boy. He found also, that he could communicate electricity to fluid bodies, by insulating them upon a cake of rosin; and observed, that when an excited tube was held over a cup of water, the water was presently attracted, in a conical form, towards the tube; that the electric matter passed from the tube to the water with a slight flash and a crackling noise; and that the fluid subsided with a tremulous and waving motion.

After this period the spirit of philosophy in this branch was no longer confined to England. M. Du Fay, intendant of the French king's gardens, added to the stock of discoveries. He found that all bodies, except metallic, soft, and fluid ones, might be made electric by first heating them, and then rubbing them on any sort of cloth. He also excepts those substances which grow soft by heat, as gums, or which dissolve in water, as glue. In pursuing Mr. Grey's experiments with a packthread, &c. he perceived that they succeeded better by wetting the line. To prove the effect of this wonderful agent on the animal body, he suspended himself by silk cords, as Mr. Grey had suspended the boy, and in this situation he observed, that as soon as he was electrified, if another person approached him, and brought his hand or a metal rod within an inch of his body, there immediately issued from it one or more prickling shoots, attended with a snapping noise; and he adds, that this experiment occasioned a similar sensation in the person who placed his hand near him. In the dark he observed that these snappings were occasioned by so many sparks of fire.

Mr. Grey, on resuming his experiments, immediately concluded from that of M. Du Fay, in which a piece of metal drew sparks from the person electrified, and suspended on silk lines, that if the person and the metal changed places, the effect would be the same. He accordingly suspended a piece of metal by silk threads near his excited tube, and found that he drew sparks from it at pleasure. This was the origin of metallic conductors. Mr. Grey suspected that the electric fire might be of the same nature with thunder and lightning.

To the philosophers of Germany we are indebted for

most of the improvements in the electrical apparatus. They revived the use of the globe, which had been invented by Mr. Hawksbee, which was afterwards superseded by a cylinder, and to which they imparted a circular motion by means of wheels, and used a woollen rubber instead of the hand. By the great force also of their machines they were able to set on fire some of the most inflammable substances, such as highly rectified spirits, by the electric spark.

But the most surprising discovery was that which immediately followed these attempts, in the years 1745-6, viz. the method of accumulating the electric power by the Leyden phial. M. Von Kleist, dean of the cathedral of Camnin, was the first who found that a nail or brass wire, confined in an apothecary's phial, and exposed to the electrifying glass, or to the prime conductor, had a power of collecting the electric virtue so as to produce the most remarkable effects. He soon found that a small quantity of fluid added to it increased the power; and successive electricians found that fluid matter, or any conducting body confined in a glass vessel, had this power of accumulating and condensing the electric virtue. The shock which an electrician is enabled to give by means of the Leyden phial is well known; and this was soon followed by another improvement, that of forming what is called the electric battery, by increasing the number of phials, or jars, by which means the force is proportionably increased. By these means the electric shock was tried upon the brute creation, and proved fatal to many of the smaller animals, which appeared as if killed by lightning. By these means also the electric matter was conveyed to great distances: by the French philosophers, for near three miles; and by Dr. Watson, and some other members of the Royal Society, it was conveyed by a wire over the river Thames, and back again through the river, and spirits were kindled by the electric fire which had passed through the river. In another experiment by the same gentleman, it was found that the electric matter made a circuit of about four miles instantaneously.

The next discovery respects the nature, or rather the origin, of the electric matter. Dr. Watson was first induced to suspect that the glass tubes and globes did not contain the electric power in themselves, by observing, that upon rubbing the glass tube while he was standing on cakes of wax, in order to prevent, as he expected, any of the electric matter from discharging itself through his body on the floor, the power was so much lessened, that no snapping could be observed upon another person's touching any part of his body; but that if a person not electrified held his hand near the tube while it was rubbed, the snapping was very sensible. The event was the same when the globe was whirled in similar circumstances; for if the man who turned the wheel, and who, together with the machine, was suspended upon silk, touched the floor with one foot, the fire appeared upon the conductor; but if he kept himself free from any communication with the floor, no fire was produced. From these and other decisive experiments, Dr. Watson concludes, that these globes and tubes are no more than the first movers or determiners of the electric power.

M. Du Fay had made a distinction of two different species of electricity, one of which he called the vitreous, and the other the resinous electricity; and soon after the discovery of the Leyden phial, it was found, that by coating the outside of the phial with a conducting substance, which communicated by a wire with the person who discharged the phial, the shock was immensely increased; and indeed it appeared that the phial could not be charged unless some conducting substance was in contact with the outside. Dr. Franklin, however, was the first who explained these phenomena. He showed that the surplus of electricity, which was received by one of the coated surfaces of the phial, was actually taken from the other; and that one was possessed of less than its natural share of the electric matter, while the other had a superabundance. These two different states of bodies, with respect to their portion of electricity, he distinguished by the terms plus or positive, and minus or negative; and it was inferred from the appearances that bodies which exhibited what M. Du Fay called the resinous electricty, were in the state of minus, that is, in the state of attracting the electric matter from other bodies, while those which were possessed of the vitreous electricity were bodies electrified plus, or in a state capable of imparting electricity to other bodies. By this discovery Dr. Franklin was enabled to increase the electic power almost at pleasure, namely, by connecting the inside of one phial with the inside of another, in such a manner that the fluid which was driven out of the first would be received by the second, and what was driven out of the second would be received by the third, &c. and this constitutes what we now call an electrical battery.

But the most astonishing discovery which Franklin, or perhaps any other person, ever made in this branch of science, was the demonstration of what had been slightly suspected by others, the perfect similarity, or rather indentity, of lightning and electricity. The doctor was led to this discovery by comparing the effects of lightning with those of electricity, and by reflecting that if two gun-barrels electrified will strike at two inches, and make a loud report, what must be the effect of ten thousand acres of elctrified cloud. Not satisfied, however, with speculation, he constructed a kite with a pointed wire fixed upon it, which, during a thunder-storm, he contrived to send up into an electrical cloud. The wire in the kite attracted the lightning from the cloud, and descended along the hempen string, and was received by a key tied to the extremity of it, that part of the string which he held in his hand being of silk, that the electric virtue might stop when it came to the key. At this key he charged phials, and from the fire thus obtained he kindled spirits, and performed all the common electrical experiments.

Dr. Franklin, after this discovery, constructed an insulated rod to draw the lightning from the atmosphere into his house, in order to enable him to make experiments upon it: he also connected with it two bells, which gave him notice by their ringing when his rod was electrified. This was the origin of the metallic conductors now in general use.

It was afterwards discovered by Mr. Canton, that the positive and negative electricity, which were supposed to depend upon the nature of the excited body, and therefore had obtained the names of resinous and

vitreous, depended chiefly upon the nature of the surface; for that a glass tube, when the polished surface was destroyed, exhibited proofs of negative electricity as much as sulphur or sealing wax, and drew sparks from the knuckle when applied to it, instead of giving fire from its own body; when the tube was greased, and a rubber with a rough surface was applied to it, its positive power was restored, and the contrary when the rubber became smooth by friction.

General principles of electricity.—From the brief account which has been given of discoveries relative to this branch of science, the reader will be prepared to admit that electricity is the action of a body put in a state to attract or repel light bodies placed at a certain distance; to give a slight sensation to the skin, resembling in some measure that which we experience in meeting with a cobweb in the air; to spread an odour like the phosphorus of Kunkell; to dart pencils of light from the surface, attended with a snapping noise, on the approach of certain substances; lastly, that the body put in this state is capable of communicating to other bodies the power of producing the same effects during a certain time.

The electric power is indubitably the effect of some matter in an active state, either within or round the electrified body; since, if we place either our hands or face before an excited tube of glass, or before an insulated conductor which is electrified, we shall perceive emanations sensible to the touch; and if we approach nearer, we shall feel it distinctly, and hear a weak noise: in the dark we perceive sparks of vivid light, especially from angular points; we see emitted pencils of rays, or small flashes of divergent flame; it is certain therefore, that some subtile matter put in motion is alone capable of making these impressions upon our senses; and we may conclude that every electrified body is encompassed by some matter in motion, which is, without doubt, the immediate cause of all the electrical phenomena, and which we term the electric matter or fluid.

Thus far, and no farther, are we warranted in affirming, on the only evidence to be admitted in philosophy, that of experiment, fact, and observation. There is, however, in man, a curiosity that prompts us too look beyond effects, and a disposition that leads us to theorize, even on the most difficult subjects. Let us, however, do it with diffidence and caution. What, then, is this electric matter? or whence does it derive its origin? It apparently proceeds not from the electrified body, for that suffers no sensible diminution. It depends not on any property inherent in the air of the atmosphere, for three obvious reasons: first, because electrical phenomena may be produced in a space from which the air has been most carefully exhausted. Secondly, because the electrical matter has qualities which are not inherent in air: it penetrates certain bodies impervious to air, such as metals; it has a sensible odour; it appears itself inflamed; it is capable of inflaming other bodies, and of melting metals; effects which air cannot produce. Thirdly, its motion is considerably more rapid than that of sound, which is a motion of the air the most rapid that we are acquainted with.

It is, however, generally agreed, that the electric matter has a strong analogy with the matter of heat and light. It appears, indeed, that Nature, who is so very economical in the production of principles, whilst she multiplies their properties so liberally, has in no case established two causes for one effect. We may apply this remark to the electric matter; and the more we inquire into the properties of the electric matter, and those of the matter of heat and light, the more shall we discover of this analogy between them, and the more probable will it appear, that fire, light, and electricity, depend upon the same principle, and that they are only three different effects from the same matter or essence.

1st. Of all the means necessary to excite the matter of heat, there is none more efficacious than that which is most necessary to produce electricity, namely, friction. 2dly. As caloric extends itself with more facility in metals and humid bodies than in any other substances, so metals and water are conductors of electricity in the same manner as they are of heat; and, in general, the same conductors are found equally good for both. 3dly. Caloric is the most elastic of all bodies, and is considered by most philosophers as the principal cause of that repulsion which takes place between the particles of bodies; and to a similar cause the electric repulsion may be referred. 4thly. The pulse and perspiration of animals are increased by electricity as by the actual application of heat. 5thly. Actual ignition is produced by the electric fluid. Thus it is a common experiment to inflame spirit of wine by the electric spark; inflammable air is set on fire by the same means in the common electrical pistol; and even gunpowder may be exploded by a spark from a powerful conductor. 6thly. Metals are melted by electricity; and most inflammable substances are affected by it as by common fire, but in a weaker degree. 7thly. The light emitted by the electrical apparatus has all the properties of that which is emitted from the sun; the composition differing in some respects, according to circumstances, as to the predominancy of certain rays, the light in different instances inclining to blue, red, white, &c. according to its intensity. 8thly. The motion of light is exceedingly rapid, whether it is reflected or refracted; in the same manner the electric fluid is found to move with almost infinite velocity, for it has been proved by experiments, that a cord 1200 feet long has become instantly electric in its whole extent. The abbe' Nollet has communicated the electric shock to 200 persons at the same time, or at the least perceptible instant.

Notwithstanding these considerations, it must be confessed, that there are some facts which seem to indicate that the electric fluid is not purely and simply the matter of heat or light unmixed with other substances: for 1st, it has been observed, that the electric matter has the property of affecting the organs of scent, which is a property that belongs neither to light nor heat.

2dly. It is well known also, that an accumulation of caloric increases the fluidity of all bodies, and prevents them from congealing, whereas congealed fluids may be highly charged with electricity; nor does it appear to have the smallest effect in increasing their fluidity.

3dly. Heat spreads in every direction, whereas the electrical fluid may be arrested in its progress by certain bodies, which, on that account, have obtained the

name of con-conductors. The Torricellian vacuum, on the contrary, affords a ready passage to the electric fluid, but is a bad conductor of heat.

4thly. Whenever the matter of heat penetrates bodies, it warms as well as expands them. The electric fluid does not produce these effects; bodies, however long they may be electrified, become neither hotter to the touch, nor more extended in dimensions.

5thly. The singular property of adhering to certain conductors, without diffusing itself to other substances, which may be even in contract with them, so observable in the electrical fluid, is a property not common to caloric or elementary fire. Thus we have seen that spirits were kindled by an electrical spark drawn by a wire through the water of the Thames; and large pieces of iron wire have been heated red-hot, while immersed in water, by an electrical explosion.

6thly. With respect to the identity of light and electricity, it should also be recollected, that light pervades glass with the greatest facility, whereas that substance is penetrated by the electrical fluid only in certain circumstances, and with the utmost difficulty; if, therefore, it should be admitted, that the basis of the electric matter is radically the same with the matter of heat or light, it seems necessary to admit also, that it retains some other matter in combination with it, of the nature of which we are as yet uninformed; and it is probably this combination of foreign matter which disables it, in ordinary cases, from penetrating glass. At present, however, we know nothing for a certainty concerning the electrical fluid, but some of its effects.

Electrical phenomena are produced by friction, and by communication. In general, bodies which electrify the best by friction, electrify the worst by communication (except glass in certain circumstances); and on the contrary, substances which electrify the best by communication electrify the worst by friction. We shall begin with those experiments which gave rise to the principal technical terms made use of in this science.

If a dry glass tube is rubbed with a piece of dry silk, and if light bodies, as feathers, pith balls, &c. are presented to it, they will be first attracted and then repelled. The best rubber for a smooth glass tube is a piece of black or oiled silk, on which a little amalgam has been spread: sealing-wax, rubbed with new and soft flannel, will produce the same effect. By this friction an agent or power is put in action, and this power is called the electrical fluid: a certain quantity of this fluid is supposed to exist latent in all bodies, in which state it makes no impression on our senses; but when by the powers of nature or of art, this equilibrium is destroyed, and the agency of the fluid is rendered perceptible to the senses, then those effects are produced which are termed electrical, and the body is said to be electrified.

If a homogeneous body is presented to the excited tube, so as to receive electricity from it, and the electricity remains at or near the end or part presented, without being communicated to the rest of the body, it is called a non-conductor or electric; but if, on the contrary, the electricity is communicated to every part, the body is called a conductor, or non-electric. A body is said to be insulated when it communicates with nothing but electrics, as when it is placed upon glass pillars, or a ball of wax or rosin, or any non-conducting substance.

A conductor cannot be electrified while it communicates with the earth, either by direct contact or by the interposition of other conductors, because the electricity is immediately conveyed away to the earth.

A mutual attraction is exerted between a body in a state of electricity and all non-electric bodies, which, if not large and heavy, will pass rapidly through the air to the electrified body, where they remain till they have, by communication, acquired the same state, when they will be repelled. If an uninsulated conductor is at hand, it will attract the small body when electrified, and deprive it of its electricity, so that it will be again attracted by the electrified body, and repelled as before, and will continue to pass and repass between the two, till the electric state is entirely destroyed.

The following is a list of electrics, and also of conductors, disposed according to the order of their perfection, beginning in each column with the most perfect of their class: thus glass is a more perfect electric than amber, and gold is a better conductor than silver.

ELECTRICS.	CONDUCTORS.
Glass of all kinds.	All the metals in the following order:
All precious stones, the most transparent the best.	Gold; silver; platina; brass; iron; tin; quicksilver; lead.
Amber.	The semi-metals.
Sulphur.	Metallic ores.
All resinous substances.	Charcoal.
Wax of all kinds.	The fluids of the animal body.
Silk and cotton.	Water, especially salt water, and other fluids, except oil.
Dry external animal substances, as feathers, wool, and hair.	Ice, snow.
Paper.	Most saline substances.
Loaf sugar.	Earthy substances.
Air when dry.	Smoke, steam, and even a vacuum.
Oils and metallic oxides.	
Ashes of animal and vegetable substances.	
Most hard stones.	

M. Achard, of Berlin, has proved by experiment, that under certain circumstances a body will become a conductor of electricity, which before was a non-conductor. The principal of these circumstances are the degrees of heat to which the body is subjected.

It must be observed, however, that electrics and non-electrics are not so strongly marked by nature as to be defined with precision; for the same substance has been differently classed by different writers: besides, the electric properties of the same substance vary according to changes of circumstances: thus a piece of green wood is a conductor; and the same piece, after it has been baked, becomes a non-conductor; when it is formed into charcoal, it again conducts the electric matter; but when reduced to ashes, is impervious to it. Indeed, it might perhaps be generally said, that every substance is in a certain degree a conductor of this fluid, though some conduct it with much more facility than others.

When electricity became a science, so far as to attract the notice of philosophers, various modes were employ-

ed for producing or accumulating the electrical matters.

The first electrical machine made use of was a tube of glass, which, being excited by friction, was then put in a state to communicate electricity to other bodies. The best glass for this purpose is the fine white English crystal. The most convenient dimensions for these tubes are about three feet in length, twelve or fifteen lines in diameter, and the glass quite a line in thickness. It is of little importance whether the tube is open or closed at the extremities; yet it is necessary that the air within should be in the same state as that without: for this reason the tube should at least be open at one end; but care must be taken that dust should not be admitted into the inside, for that would considerably impede its effects. If, notwithstanding these precautions, the tube receives either dust or moisture, some dry and fine sand should be introduced into the inside, and it should be afterwards cleaned out with fine dry cotton.

When it is intended to electrify a tube, it is only necessary to take the end in one hand, and to continue to rub the tube with the other hand, from one end to the other, until it affords marks of its being sufficiently charged with the electric fluid. This friction may be performed with the naked hand when it is dry and clean, otherwise with a piece of soft brown paper, or waxed taffeta. When the tube has been rubbed in this manner, the circumambient air being dry, if light substances are presented to it, they will be first attracted towards it, and immediately afterwards repelled.

The electric fluid may be excited in nearly a similar manner, by rubbing a stick of sulphur or sealing-wax.

These tubes being but small, the quantity of electricity produced is but feeble in its effects. We have seen that a method was contrived to turn a globe of glass upon its axis by means of a machine with a winch or multiplying wheel: this method admitted of a larger surface, and the friction was performed with greater ease, by means of a rubber being placed close to the revolving globe. The electrifying machine has however since undergone various improvements, and perhaps is capable of still more.

In the plate XLVIII. fig. 1. is a representation of an electrical machine with a prime conductor. ABC represents the bottom board of the machine, D and E the two perpendicular supports which sustain the glass cylinder FG. The axis of the cap K passes through the support D; on the extremity of this axis a simple winch L is fixed. The axis of the other cap runs in a small hole, which is made in the top of the supporter E.

P is the glass pillar to which the cushion is fixed; T a brass screw at the bottom of this pillar, which is to regulate the pressure of the cushion against the cylinder. This adjusting screw is peculiarly advantageous: by it the operator is enabled to lessen or increase gradually the pressure of the cushion, which it effects in a much neater manner than it is possible to do when the insulating pillar is fixed on a sliding-board.

Y represents the positive prime conductor, or that which takes the electric fluid immediately from the cylinder; M the glass pillar by which it is supported and insulated; and X a wooden foot or base for the glass pillar.

Fig. 2. is a plate glass machine, of the most portable construction, with a double Leyden phial made square to suit the base, which answers all the purposes of medical electricity. ABC is a wooden frame to which the four rubbers are affixed, and by means of screws may be made to bear with proper pressure on the circular glass plate DF; this plate has a hole through its middle, to which an axis is firmly fixed, and it is turned by the winch L; GG is a Leyden phial (with the collector so fixed on the top) fixed in a larger one H: when a strong shock is wanted, the long pin I is let in to touch the bottom, by which means the large jar acts: but when drawn out, the small one acts alone but much quicker, from being inclosed in the other. K is the electrometer. When this machine is constructed on a large scale for experiments, a prime conductor M, fig. 4, may be attached to the wooden frame opposite the axis of the plate-glass instead of the jar. Fig. 3 is a side view of the machine, with a clamp N to fix it to the table when used.

The advantages of this machine are, that it may be made portable, and is of so simple a construction, that any gentleman in the country, after procuring a plate of a reasonable thickness from a glass-house, may, by the aid of a common cabinet-maker, construct one for his own use; the conductor may be equally insulated by rosin, wax, silk, or any other electric or non-conducting substance.

When of a large diameter, these plate machines are by far the most powerful of any; and this power is greatly increased by a second plate parallel to the other, and turning on the same axis. The most powerful machine of which we have ever heard is one made in England for the museum of Teylar, at Harlem. It consists of two circular plates of five feet five inches diameter. The plates are about $7\frac{1}{2}$ inches asunder, and each is excited by four rubbers. The prime conductor is divided into two branches which enter between the plates, and by means of points collect the electrical fluid. These plate machines, however, with two plates, are turned with great labour, and are liable to more accidents when large than the common cylinders.

Previous to the consideration of these circumstances, by which a large quantity of the electric fluid may be excited, it may be necessary to premise, that the resistance of the air seems to be lessened where the cushion is in close contact with the cylinder; and that the electric matter, agreeably to the law observed by all other elastic fluids, is pressed towards that part where it finds least resistance; the same instant, therefore, that the cylinder is separated from the cushion, the fire issues forth in abundance, because the resistance made to it by the action of the atmosphere is lessened at that part. The more perfect the continuity is made, the greater is the quantity of electricity which will proceed from the cushion.

To excite, therefore, an electrical machine effectually, it is necessary first to discover those parts of the cushion which are pressed by the glass cylinder, and then the amalgam must be applied to those parts only. The line of contact between the cylinder and cushion must be made as perfect as possible, and the fire which is collected must be prevented from escaping. The

breadth of the cushion should not be great, and it should be placed in such a manner that it may be easily raised or lowered.

In order to find the line of contact between the cylinder and cushion, place a line of whiting which has been dissolved in spirit of wine, on the cylinder: on turning this round, the whiting is deposited on the cushion, and marks those parts of it which bear or rub against the cylinder. The amalgam is to be put on those parts only which are thus marked by the whiting.

Whenever the electricity of the cylinder grows less powerful, it is easily renewed by turning back the silk which lies over it, and then rubbing the cylinder with the amalgamated leather, or by altering the pressure of the adjusting screw.

A small quantity of tallow placed over the amalgam is observed to give more force to the electric powers of the cylinder; or the same end may be effected by rubbing the cylinder with a coarse cloth, which has been a little greased, and afterwards wiping it with a clean cloth.

As air not only resists the emission of the electric fluid, but also dissipates what is collected, on account of the conducting substances which are floating in it, over the cylinder a piece of black or oiled silk should be placed, from the line of contact to the collecting points of the prime conductor, and these points should be placed within its atmosphere.

Sometimes the silk will adhere so strongly to the cylinder, when zinc amalgam is used, as to render it very difficulty to turn; but this may be obviated by rubbing a small quantity of aurum musivum, or a little whiting, over the silk, when it is wiped clean.

The following directions of Mr. Adams, relative to exciting the machine, will be useful to the experimentalist:

"To excite your machine, clean the cylinder, and wipe the silk.

"Grease the cylinder by turning it against a greasy leather, till it is uniformly obscured. The tallow of a candle may be used.

"Turn the cylinder till the silk flap has wiped off so much of the grease as to render it semi-transparent.

"Put some amalgam on a piece of leather, and spread it well, so that it may be uniformly bright: apply this against the turning cylinder, the friction will immediately increase, and the leather must not be removed until it ceases to become greater.

"Remove the leather, and the action of the machine will be very strong.

"The pressure of the cushion cannot be too small, when the excitation is properly made."

There are now in use two kinds of amalgam: one is made of quicksilver five parts, zinc one part, which are melted together with a small quantity of bees-wax; the other is the aurum musivum of the shops, which is tin and sulphur. Before either of these will adhere closely to the silk it is necessary to grease it, to wipe off the superfluous grease, and then spread the amalgam.

One property of the electric fluid it will be necessary to notice before the conclusion of this branch of the subject, and that is, that it is more forcibly attracted by points than by balls or any blunt or rounded surfaces. This may be demonstrated by a variety of easy experiments, and may be seen by presenting a metal ball at a given distance to a conductor in the act of being charged, when it will be found that a metal point presented at a much greater distance will draw off the whole of the electrical matter from the conductor. In the one case also (the point) the electricity goes off invisibly, and without noise; in the other case there are both a flash and a report.

Of the theory of electricity.—In a very early stage of the science we have seen, that a distinction was observed with respect to the attractive and repulsive powers of certain electric bodies. Thus, if we electrify with the same substance, for instance either with excited glass or with sealing-wax, two cork balls in an insulated state, that is, suspended by silk lines about six inches long, the balls will separate and repel each other; but if we electrify one of the balls with glass, and the other with sealing-wax, they will be mutually attracted. This circumstance gave rise to the opinion, that two different species of electricity existed; and the one was termed the vitreous electricity, or that produced from glass; and the other, which was produced from sealing-wax, resinous substances, and sulphur, was termed the resinous electricity.

Subsequent experiments served to show, that in the common electrical machine, the rubber exhibited the appearance of the resinous electricity, and the cylinder that of the vitreous, while the former was connected with the earth. A divergent cone or brush of electrical light was observed to be the obvious mark of the vitreous electricity; and a single globular mass of light distinguished the resinous kind. The hand or body also which approached the vitreous or glassy substance, when excited, appeared to receive the matter from the electric; but when one of the resinous kind was excited, the electrical matter appeared to proceed from the hand or other approaching body.

Notwithstanding, however, the names by which these different forms of electricty were distinguished, as the vitreous and resinous, it was at length discovered, that the different phenomena depended rather upon the surface, than upon the nature and composition of the electric; for a glass tube, when the polished surface was destroyed, by being ground with emery, and being rubbed with a smooth body, exhibited all the proofs of the resinous electricity, as much as sulphur or sealing-wax; yet afterwards, when it was greased and rubbed with a rough surface, it resumed its former property. It seems, therefore, to be a rule, that the smoothest of two bodies, upon friction, exhibits the phenomena of the vitreous electricity; for baked wooden cylinders with a smooth rubber are resinously electrified, but with a rubber of coarse flannel they exhibit the appearances of the vitreous kind; and even polished glass will produce the phenomena of the resinous electricity, if rubbed with the smooth hair of a cat's skin.

Amidst this embarrassing variety of experiments, those philosophers who applied to this branch of science, were eagerly employed in inventing theories to account for these phenomena, and electricians are still divided with respect to the cause.

The theory of Franklin, though not without its de-

fects, possesses simplicity, and accounts for facts in an easy and natural manner. It may be resolved into the following axioms:

1st. The electric matter is one and the same in all bodies, and is not of two distinct kinds.

2d. All terrestrial bodies contain a quantity of this matter.

3d. The electric matter violently repels itself, but attracts all other matter.

4th. Glass and other substances, denominated electrics, contain a large portion of this matter, but are not to be penetrated by it.

5th. Conducting substances are permeable by it, and do not conduct it merely over their surface.

6th. A body may contain a superfluous quantity of the electrical fluid, when it is said, according to this theory, to be in a *positive* state, or electrified *plus;* and when it contains less than its proper share, it is said to be *negative*, or electrified *minus*.

7th. By exciting an electric, the equilibrium of the fluid is broken, and the one body becomes overloaded with electricity, while the other is deprived of its natural share.

Thus, according to the Franklinean theory, that electricity, which was before called *vitreous*, is now called *positive* electricity; and that which was termed the *resinous*, is now denominated *negative* electricity.

It is evident, that it is only in passing from one body to another, that the effects of the electrical fluid are apparent. When all the adjacent bodies, therefore, are equally charged with electricity, no effects whatever will appear. The equilibrium must, according to the principles of Dr. Franklin, be destroyed, that is, the fluid must be made rarer in some one part, before any of the phenomena will be exhibited. In that case, the dense fluid rushing in to supply the deficiency in that part where it is rarer, produces the flash of light, the crackling noise, and the other effects of electricity.

The different effects on rough and smooth bodies, when excited, have been previously remarked. The Franklinean theory is, if a rough and smooth body are rubbed together, the smooth body will generally be electrified *plus*, and that with a rough uneven surface, *minus*. Thus, in the ordinary operation of the common machine, the cylinder is positively electrified, or plus, and the rubber negative, or minus. The redundance of the positive electricity is sent from the cylinder to the prime conductor, and may be communicated from it to any conducting body. If, however, the prime conductor is made to communicate with the earth, which has a great attraction for the electrical matter (and which, being one great mass of conducting substances, will not permit the accumulation of the fluid in a particular part); and if, at the same time, the rubber is in an insulated state, supported, for instance, by glass or any electric; these effects will be reversed, for the prime conductor will then be negatively electrified, and the rubber will be plus or positive.

Dr. Franklin supposed that the electric fluid is collected from the earth, and this hypothesis he supported by the following experiment.

Let one person stand on wax (or be insulated) and rub a glass tube, and let another person on wax take the fire from the first, they will both of them (provided they do not touch each other) appear to be electrified to a person standing on the floor; that is, he will perceive a spark on approaching either of them with his knuckle or finger; but if they touch each other during the excitation of the tube, neither of them will appear to be electrified. If they touch one another after exciting the tube, and draw the fire as before, there will be a stronger spark between them than was between either of them and the person on the floor. After such a strong spark, neither of them discovers *any electricity*.

He accounts for these appearances by supposing the electric fluid to be a common element, of which each of the three persons has his equal share before any operation is begun with the tube.

A, who stands upon wax and rubs the tube, collects the electrical fire from himself into the glass, and his communication with the common stock being cut off by the wax, his body is not again immediately supplied.

B, who also stands upon wax, passing his knuckle along the tube, receives the fire which was collected from A, and, being insulated, he retains this additional quantity.

To the third person C, who stands upon the floor, both appear electrified; for he, having only the middle quantity of electrical fire, receives a spark on approaching B, who has an over quantity, but gives one to A, who has an under quantity.

If A and B approach to touch each other, the spark is stronger, because the difference between them is greater. After this touch there is no spark between either of them and C, because the electrical fluid in all is reduced to the original equality. If they touch while electrifying, the equality is never destroyed, the fire is only circulating; hence we say that B is electrified positively, A negatively.

Such is the famous Franklinean hypothesis, which, it must be confessed, is not entirely without its difficulties, and, it is much to be feared, that we have as yet no complete theory of electricity. The fact most difficult to be explained on the Franklinean system is, that of two bodies negatively electrified repelling each other; for if the repulsion in the case of positive electricity is caused entirely, as there is reason to believe it is, by the electric matter, how should a deficiency of that matter produce the same effect? Attempts have been made to explain the fact, by having recourse to the electricity of the air, which (when not charged with moisture) is certainly an electric, or non-conducting substance, and in all cases is an imperfect electric. The cork balls, or other light substances, which are electrified negatively, are therefore supposed to be acted upon by the positive electricity of the air, which produces an effect adequate to the being positively electrified. This solution, however, is not quite satisfactory; though it is perhaps unphilosophical to reject an hypothesis, which explains some facts greatly to our satisfaction, merely because it has not as yet explained every thing.

But leaving theories, especially in the present very imperfect state of this science, let us endeavour to keep our attention on those facts which are well known, and generally admitted. The following statement seems to comprise the general principles on which this wonderful

fluid is known to act. It is extracted from M. Brisson, a French writer of deserved reputation, and it is such as a few easy experiments will serve to confirm.

The electric fluid is probably the same in essence with that of light and heat, but combined with a substance which affects the organs of scent.

When bodies are electrified by glass, they furnish tufts or pencils of light; but if electrified by sulphur, or resinous substances, they only produce points, or sparks of light; bodies presented to those electrified by glass, produce only luminous points: while those which are presented to bodies which are electrified by sulphur, produce beautiful pencils, or tufts of light.

Bodies are electrified either by friction or communication. To electrify bodies by communication, it is necessary to insulate them; and the substances the most proper for insulating others are those which electrify the best by friction.

Glass, however, though it electrifies very well by friction, electrifies also by communication, even without any preliminary preparation; yet it is very proper for insulating.

The electrical matter is not produced entirely from the bodies upon which the electrifying machine acts; the adjacent bodies, or substances, combine towards its production.

The energy of the electric virtue is augmented, in conductors, more by an increase of surface, than by an augmentation of the mass.

Electrified bodies adhere one to another, so that, on some occasions, they cannot be separated without a considerable effort.

Electricity accelerates the evaporation of liquors, and the perspiration of animals.

The pencils or tufts of light, which are seen at the extremities or angles of electrified bodies, are always composed of divergent rays when they pass through the air; but if a *non-electric*, or conducting body, is presented to them, they lose a great deal of their divergency; their rays sometimes become even convergent, in order that they may approach towards that body which is more permeable than the air; and if they are made to pass into a vacuum, they will assume the form of a large branch of light nearly cylindrical, or in the form of a spindle.

The spark which shines between two bodies is capable of setting combustible matters on fire.

Electrical instruments, or apparatus.—The experiments in electricity are so various, that the apparatus may be increased almost agreeably to every man's fancy; and, in general, he who wishes to make new experiments, will find it necessary to make an addition suited to the object of his inquiry. It will be, therefore, proper, on the present occasion, and most consistent with the design of this work, only to specify and describe those parts of the apparatus which are most in use, and essential to the performance of the experiments which are already before the public.

The instruments commonly employed in this branch of science, may be classed under six heads: 1st. The instruments used for exciting electricity, viz. glass tubes, plates, and cylinders. 2d. Those for conducting the electric matter, which are chiefly of metal. 3d. Those intended for accumulating the fluid, or, in technical language, for receiving a *charge*, such as coated bottles or jars, commonly called Leyden phials. 4th. Those which are intended to produce more formidable effects, such as electric batteries. 5th. The instruments employed for ascertaining the quantity of electricity, called electrometers; and lastly, those employed for retaining the electric power.

I. Of the first class of these instruments it was necessary to treat, in explaining the first principles of electricity; and there is nothing that can be added in further illustration of the nature of electrical machines.

II. The nature and uses of such conductors as are attached to the machine, have been also explained; but any instrument which serves to convey the electrical influence from one body to another, may be regarded as a conductor. With this view, wires and chains are employed to form a communication between different bodies; and under this head we may also class the common discharging rod, the principle of which consists in a rod of metal, sometimes with knobs at the ends, which is furnished with a glass handle, to prevent the shock from passing through the body of the operator. In plate XLVIII. fig. 5. is the jointed discharging rod, which is most commonly used. D is the glass handle cemented into the brass socket C; and *e f* are the brass wires, which are curved, and may be opened by the joint to any extent that may be required. The wires are pointed, as it is sometimes necessary to draw off a charge in that way; and the knobs *a b* are made to screw, or sometimes only to fit on to the ends of the wires. It is frequently used without the knobs, particularly in discharging large jars and batteries. See fig. 6.

Henley's universal discharger consists of two wires, supported by glass feet, with a small table between them to support any thing that may be the object of the experiment. It is found to be a very useful instrument for a variety of purposes, and is composed of the following parts: A (fig. 7.) is a flat board, about fifteen inches long, four broad, and one thick. BB are two glass pillars, cemented in two holes upon the board A, and furnished at top with brass caps, each of which has a turning joint, and supports a spring tube, through which the wires DD slide. Each of the caps is composed of three pieces of brass, connected so that the wires DD, besides their sliding through the sockets, have a horizontal and vertical motion. Each of the wires DD is furnished with an open ring at one end, and at the other it has a brass ball, which, by a short spring socket, is slipt upon the pointed extremity, and may be removed. E is a circular piece of wood, having on its surface a slip of ivory inlaid, and furnished with a foot, which is fastened in the middle of the bottom A.

There is another part of an electrical apparatus, originally of German invention, which, before we conclude this branch of the subject, it may not be improper to notice, as it is chiefly illustrative of the electrical attraction. This apparatus consists of three small bells, (fig. 8.) suspended from a narrow plate of metal; the two outermost by chains, and that in the middle (from which a chain RS passes to the floor) by a silken sting. Two small knobs of brass are also hung, by silken strings, on

each side of the bell in the middle, which serve for clappers.

If an apparatus of this kind is joined to one of those conducting rods, erected to protect buildings from the effects of lightning, it will serve to give notice of the approach and passage of an electrical cloud.

III. In the infancy of every science, the inventions are simple. The first telescope was formed of two spectacle-glasses fixed upon a board; the first electrical bottle was a common apothecaries' phial, with an iron nail in the inside, which was afterwards changed for a wire. The artist who framed the one, did not expect that his discovery would enable future philosophers to explore and measure the face of a planet, or to count the host of heaven; nor did the inventor of the other, probably, suppose that his little phial, in the hands of future operators, would enable human power to vie with the most formidable of nature's efforts, to melt the hardest metals, and even to deprive plants and animals of life.

It would be an error, however, to suppose that on the form of the glass depends the success of the experiment. If any piece of glass, of whatever form, cylindrical or otherwise, is coated with a conducting substance, it may be made to accumulate the electrical matter. In this case, one side of the glass, if it does not exceed a given thickness, will be positively electrified, and the other negatively.

As, however, flat plates are neither necessary nor convenient for this purpose, jars, or bottles with wide necks, are usually employed. These are made of various shapes and magnitudes, but the most useful are thin cylindrical glass vessels, about four inches in diameter, and fourteen in height, coated within and without (except about two or three inches from the top) with tin-foil, or any other conducting substance.

If one side of this jar is electrified, while the other side communicates with the earth, it is said to be charged.

When a communication is formed from one side of the jar to the other by a conducting substance, after it has been charged, an explosion will take place, and this is called discharging the jar. The jar, however, is incapable of being charged when it is insulated; that is, when neither side communicates with the earth. When it is charged, the two sides are in contrary states; the one being positively, the other negatively electrified.

A jar is said to be positively electrified, when the inside receives the fluid from the conductor, and the outside is connected with the earth. It is negatively electrified when the outside receives the fluid from the conductor, and the inside communicates with the earth; but it is necessary that the jar charging negatively should be insulated, because the fluid is, in the first instance, conveyed to the coating, and would be immediately carried to the earth if it was not prevented by the interposition of an electric substance.

The most usual forms of the Leyden phial, or electrical jar, are represented in figs. 6, 9, and 10, and its nature may be exemplified by the following easy experiments.

Place the jar (fig. 6) on a table, or any other non-electric body which communicates with the earth, and let the ball on the top be about one-eighth of an inch from the ball of the conductor *y*. If the machine is turned, sparks may be perceived passing from the ball of the conductor to the ball of the jar. When this effect ceases, and no more sparks are perceived to pass from the conductor, the jar may be considered as charged, the inside positively, and the outside negatively. To discharge the jar, all that is necessary is to form a communication between the outer and the inner coating of the jar or phial, that the surplus electricity may be conveyed from the one to the other. To avoid the painful sensation which is the consequence of the shock, this is usually performed with the discharging rod, see figs. 5 and 6. The operator then holds the rod by the glass handle D, and all that is necessary is to place one knob close to the outer coating, and then bring the other knob near the ball of the jar, when it will be discharged with an explosion proportioned to the quantity of electricity it has received. If, when the jar is charged, a person touches the outside with one hand, and brings the other near the knob of the jar, he will then receive the shock. A chain is sometimes concealed under the carpet, connected with the outside coating, and another is connected with the top of the jar; if then a person standing on the one, is induced to put his hand incautiously on the other chain, he will receive a shock, to his great surprise and the entertainment of the company: but care should be taken that the shock should not, in this case, be too strong. Mr. Canton used to amuse himself in this way, by electrifying the latch of his door, which was insulated, and giving a shock to the venders of old cloths, whom he allured by a well known signal, to the magic ground. An optician in London, some years ago, being teazed by an impertinent neighbour, who amused himself with knocking at his door, contrived to insulate the knocker, which was connected, by a wire, with a charged jar, and, on the unfortunate adventurer attempting to repeat his accustomed intrusion, he received a charge, which, it is reported, felled him to the ground.

To illustrate further the nature of the Leyden phial, place the same jar, fig. 6, on an insulated stand; bring the coating in contact with the conductor; turn the machine, and, after a few turns, remove the phial from the conductor; then form a communication between the outside and the inside of the phial, by means of the discharging rod; in this case, there will be no explosion, because, both sides being insulated, the bottle was not charged; but if a chain is suspended from the brass ball of the phial to the table, and the coating brought in contact with the conductor, after a few turns of the machine, remove the phial as before; then if the discharger is applied, an explosion will be heard, and the bottle will be discharged; because, in this case, the insulation of the inside is destroyed by the chain, and the phial becomes capable of receiving a charge.

That the charge of a coated jar resides in the glass, and not in the coating, is proved in the following manner: Set a plate of glass between two metallic plates, about two inches in diameter, smaller than the plate of glass; charge the glass, and then remove the upper metallic plate by an insulated handle; take up the glass plate, and place it between two other plates of metal unelectrified and insulated, and the plate of glass thus coated afresh will still be charged. The following experi-

ments are further illustrative of the nature of the Leyden phial.

A cork ball, or an artificial spider made of burnt cork, with legs of linen thread, suspended by silk, will play between the knobs of two bottles, one of which is charged positively, the other negatively, and will, in a little time, discharge them. See fig. 10.

A ball suspended on silk, and placed between two brass balls, one proceeding from the outside, the other from the inside of a Leyden jar, when the bottle is charged, will fly from one knob to the other, and by thus conveying the fluid from the inside to the outside of the bottle will soon discharge it.

An insulated cork ball, after having received a spark, will not play between, but be equally repelled by two bottles, which are charged with the same power.

A wire is sometimes fixed to the under part of the insulated coated phial (fig. 13) plate XLIX.; and *b c* is another wire fitted to the former, and at right angles with it; a brass fly (fig. 14) is placed on the point of this wire; charge the bottle, and all the time the bottle is charging the fly will turn round; when it is charged the motion will cease. If the top of the bottle is touched with the finger, or any other conducting substance, the fly will turn again till the bottle is discharged. The fly will electrify a pair of balls positively while the bottle is charging, and negatively when it is discharging.

When a Leyden phial, positively charged, is insulated, it will give a spark from its knob to an excited stick of wax, but not a spark will pass at that time between it and an excited glass tube.

An additional quantity of the fluid may be thrown on one side of the jar, if, by any contrivance, an equal quantity be made to escape from the other, and not otherwise.

IV. Electricians, in order to increase the force of the electric explosion, connect several jars, or Leyden phials, together in a box; and this is called an electrical battery.

Fig. 12 is a battery composed of twelve jars, coated on the inside and outside with tinfoil, which altogether contain about twelve feet of coated glass. About the middle of each of the jars is a cork that sustains a wire, which, at the top, is fastened round, or soldered to the wire, knobbed at each end; which connects the inside coatings of three jars; and by four wires, such as C, D, E, F, the inside coatings of all the twelve jars may be connected together.

The square box that contains these jars is of wood, lined at the bottom with tin-foil, and has two handles on two opposite sides, by which it may be easily removed. In one side of the box is a hole, through this an iron hook passes, which communicates with the metallic lining of the box, and consequently with the outside coating of all the jars. To this hook is fastened a wire, the other end of which is connected with the discharging rod.

The battery represented in the plate, is a small one, in comparison to those now frequently used, and much too weak for the purpose of some experiments. But it is sufficient to give an idea of its construction; and when a large battery is to be constructed, it is better to make two, three, or more small ones, as represented in the plate, than a single large battery, which is heavy, and, on several accounts, inconvenient. The force of several small batteries may be easily united by a wire or chain; and thus they may be made to act in every respect like a large one. The best construction of a battery is to have a wire from every jar, connected with a ball at the top, in form of a wire-cage.

The force of accumulated electricity, great as it appears by the experiments performed with a single coated jar, is very small when compared with that which produced by a number of jars connected together; and if the effects of a single jar are surprizing, the prodigious force of a large battery is certainly astonishing. Expements of this kind should be conducted with great caution; and the operator ought to be attentive not only to the business in hand, but also to the persons who may happen to be near him, prohibiting their touching, or even coming too near any part of the apparatus: for if a mistake in performing other experiments may be disagreeable, those in the discharge of a large battery may be attended with dangerous consequences.

When a battery is to be charged, instead of a large prime conductor, a small one is much more convenient: for, in this case, the dissipation of the electricity is not so considerable. The quadrant electrometer, hereafter to be described, which shows the height of the charge in the battery, may be fixed either upon the prime conductor, or upon the battery; in which case, it should be fixed upon a rod proceeding from the wires of the jars; and if the battery is very large, it should be elevated two or three feet above them.

The index to the electrometer, in charging a large battery, will seldom rise so high as 90, because the machine cannot charge a battery so high in proportion as a single jar. Its limits are often about 60° or 70°, more or less, in proportion to the size of the battery and the force of the machine.

Every broken jar in a battery must be taken away, before it is possible to charge the rest.

It has been recommended, not to discharge a battery through a good conductor, if the circuit is not at least five feet long; but it must be observed, that in proportion to the lengthening of the circuit the force of the shock will be lessened.

Jars made of the green glass manufactured at Newcastle, are said to endure an explosion without a probability of breaking.

If the spark from the explosion is concentrated, by causing it to pass through small circuits of non-conducting substances, the force of the battery will be considerably increased. For this purpose, cause the sparks to pass through a hole in a plate of glass, one-twelfth or one-sixth of an inch in diameter, by which means it will be more compact and powerful. By wetting the part round the hole, the spark, by converting this into vapour, may be conveyed to a greater distance, with an increase of rapidity, attended with a louder noise than common. Mr. Morgan, by attending to these and some other circumstances, has melted wires, &c. by the means of small bottles.

If the charge of a strong battery is passed through two or three inches of small wire, the latter will sometimes appear red-hot, first at the positive side; and the redness will proceed towards the other end.

If a battery is discharged through a small steel needle, it will, if the charge is strong, communicate magnetism to the needle.

If the discharge of a battery passes through a small magnetic needle, it will destroy the polarity of the needle, and sometimes invert the poles; but it is often necessary to repeat this several times.

Dr. Priestly could melt nine inches of small iron wire at the distance of fifteen feet, but at the distance of twenty feet he could only make six inches of it red-hot, so that we may infer from this, that notwithstanding their conducting power, still metals resist in some degree the passage of the electric fluid, and therefore in estimating the conducting powers of different substances, their length must not be forgotten.

If a slender wire is inclosed in a glass tube, and a battery discharged through this wire, it will be thrown into globules of different sizes, which may be collected from the inner surface of the tube; they are often hollow, and little more than the scoria or dross of the metal.

Dr. Watson and some other gentlemen made several curious experiments to ascertain the distance to which the electric shock might be conveyed, and the velocity of its motion, which may be briefly mentioned. In the first experiment, the shock was given, and spirits inflamed by the electric matter which had been conveyed through the river Thames. In another experiment, the electric fluid was made to pass through a circuit of two miles, crossing the New River twice, going over several gravel-pits and a large field, and afterwards conveyed through a circuit of four miles. This motion was so instantaneously performed by the electric fluid, that an observer, in the middle of a circuit of two miles, felt himself shocked at the same instant that he saw the phial discharged.

V. The instruments for ascertaining the presence and the quantity of electricity in different bodies, are various. The simplest of all is a pair of little balls of cork, or rather of the pith of the elder, which is still lighter, and suspended by silk threads. When brought into contact with an electrified body, the balls will immediately diverge, and according to the degree of divergence, a judgment is formed of the degree in which the body in question is electrified. A similar effect will be produced by a light and downy feather. The pith-balls have received the name of Canton's electrometer, from the ingenious electrician who first employed them for this purpose, and they are found useful in many experiments.

For a more accurate admeasurement, that is, for ascertaining precisely the degree in which any body is electrified, an instrument somewhat less simple is required, and Henley's quadrant electrometer is in most general use. It consists (fig. 15.) of a perpendicular stem formed at top like a ball, and furnished at its lower end with a brass ferule and pin, by which it may be fixed in a hole made in the conductor, as at fig. 1. or at the top of a Leyden bottle. To the upper part of the stem, a graduated ivory semicircle is fixed, about the middle of which is a brass arm or cock, to support the axis of the index. The index is a very slender stick, which reaches from the centre of the graduated arch to the brass ferule; and to its lower extremity is fastened a small pith-ball nicely turned in a lathe. When this electrometer is in a perpendicular position, and not electrified, the index hangs parallel to the pillar; but when it is electrified, the index recedes more or less, according to the quantity of electricity.

Lane's discharging electrometer, as it is commonly called, is employed chiefly by the practitioners of medical electricity.

It is represented by F D E, in fig. 16, and is fixed to the wire that proceeds from the inside of the jar Z. The ball B touches the prime conductor A, which is supposed to stand before an electrical machine, fig. 1. The electrometer consists in a glass rod F D, furnished with brass caps F, D: from the latter proceeds a strong brass wire, to which is attached an horizontal spring-socket: through this, the wire C E, having the ball C at one end, and the open ring E at the other, may be slided backwards and forwards, so as to place the ball C at any required distance from the ball B. Suppose the distance between B and C to be $\frac{1}{8}$th of an inch or less, and that by means of a chain X, a communication be formed from E to the outside coating of the jar. When the jar is charged so high that the fluid can leap from B to C, the discharge will take place, and the stroke pass through X from the inside to the outside of the jar. When the shocks are to be given through any part of the body, as the arm, then, instead of the chain X, wires E L and I L are to be fastened, one to the ring E, and the other to a hook at I of the stand H I which communicates with the outside of the jar. The other extremities of the wire must be fastened to the directors K, L, which consists of brass wires and balls as L fastened into glass handles K, see also fig. 11. The mode of operation is easily understood from a view of the figure (16), for when the chain X is away, the electric fluid must, in passing from the inside of the jars to the outside, go through the wire E L; the brass of the director; the part of the arm between the balls of the directors; and through the wire L I. By moving C nearer to, or farther from B, the strength of the shocks will be regulated to any degree.

The instrument represented in fig. 17, has been used successfully in the cure of the tooth-ache. A is a strong piece of box-wood in which the wires *a b c* and *c f* are fixed and then bent, the tooth and gum are placed between *c* and *f*, and the circuit between the outside and inside of the jar is to be made by means of the chains *g* and *h*, which may be fastened in the same manner as the wires E L and I L in fig. 16, and by bringing C very near to B so as not absolutely to touch, the shocks which pass through the tooth and gum will be very slight.

Several instruments have also been invented for ascertaining the state of the atmosphere with respect to the quantity of electricity it may contain, at any given time. The best of them are improvements upon Canton's electrometer, which is made by inclosing the pith-balls, or rather two slips of gold leaf, in a cylindrical glass vessel, to prevent their being affected by the wind.

Bennet's electrometer, fig. 18. is a very delicate instrument, and capable of distinguishing small quantities of electricity. It consists of two slips of leaf gold A, suspended in a glass B. The foot C may be of wood or metal; the cup D of metal. The cup is made flat on the top, that plates, books, evaporating water, or other things

to be electrified, may be conveniently placed upon it. The cup is about an inch wider in diameter than the glass, and its rim about three quarters of an inch broad; which hangs parallel to the glass, to turn off the rain, and keep it sufficiently insulated. Within this is another circular rim, about half as broad as the other, which is lined with silk or velvet, and fits close upon the outside of the glass; thus the cap fits well, and may be easily taken off to repair any accident happening to the leaf gold. Within this rim is a tin tube, hanging from the centre of the cap, somewhat longer than the depth of the inner rim. In the tube a small peg is placed, and may be occasionally taken out. To the peg, which is made round at one end and flat at the other, the slips of leaf gold are fastened with paste, gum-water, or varnish. These slips suspended by the peg, and that in the tube fast to the centre of the cap, hang in the middle of the glass, about three inches long, and a quarter of an inch broad. On one side of the cap there is a small hole to place wires in. It is evident, that without the glass, the leaf gold would be so agitated by the least motion of the air, that it would be useless: and if the electricity should be communicated to the surface of the glass, it would interfere with the repulsion of the leaf gold, therefore two long pieces, H H, of tin-foil are fastened with varnish on opposite sides of the internal surface of the glass, where the leaf gold may be expected to strike, and in connection with the foot. The upper end of the glass is covered and lined with sealing-wax as low as the outermost rim, to make its insulation more perfect.

The sensibility of this instrument is so great as even to astonish the most experienced electricians who have been witnesses of its effects. The brush of a feather, the throwing of chalk, hair-powder, or dust, against its cap, evince strong signs of electricity. The electricity of vapour is elegantly shown by pouring a teaspoonful of water on an ignited coal placed in a metallic cup upon the cap of this electrometer; and a very great and pleasing variety of other experiments may be made with this excellent instrument.

"In performing several atmospherico-electrical experiments about the year 1776, I found," says Mr. Cavallo, "that the use of Canton's cork-ball electrometer was much obstructed by the wind, in consequence of which I attempted to inclose it in a bottle, and after a variety of trials and alterations the instrument was in the year 1777 brought to the state which is represented in fig. 19. The three parts of the figure represent the instrument in its case, the same out of the case, and a section of its brass cap and neck.

"C D M N is an open glass vessel narrower at top than at bottom, and cemented into the wooden piece A B, by which part the instrument is held when it is to be presented to the atmosphere, or it may be rested upon a table for other experiments. This wooden piece also serves to screw the instrument into its wooden case O. The upper part of C D M N is tapering like the neck of a phial; and a short glass tube is cemented into it, so as to project a little above and a little within the neck of the former: then the upper part of the instrument from C D to L, is covered with sealing-wax, by means of heat, which gives it the appearance of one continuate body. The inner part G of the small glass tube is also covered with sealing-wax. Into this tube a brass wire is cemented, the lower part H of which is flattened, and is perforated with two holes; the upper part L is formed into a screw, upon which the brass cap E F is screwed. The office of this cap is to defend the upper part of the instrument from the rain. The conical, or oval, or globular, corks P of this electrometer, are as small as can be made, and are suspended by exceedingly fine silver wires, the upper parts of which are formed in rings, which pass through the holes at H, and are thereby so loosely suspended, that they are caused to diverge when the brass cap E is exposed to a very slightly electrified atmosphere. I M and K N are two narrow slips of tin-foil stuck to the inside of the glass, and communicating with the wooden bottom A B; they serve to carry off that electricity, which, when the corks touch the glass, is communicated to it, and if accumulated would disturb the free motion of the corks."

VI. It is remarkable, that in certain cases bodies electrified will retain their electric power for almost any length of time, and on this principle a very ingenious instrument has been constructed, called an electrophorus.

This simple species of electrical machine consists of two plates (fig. 20.) A and B, made of a circular form, from eight to eighteen inches in diameter, or upwards. The upper plate is generally made of brass; but a tin plate, with a wire turned in upon its edge, will answer exceedingly well. At the centre of this plate there is a socket O, in which a glass handle I, nine or ten inches long, is fixed. A thin board, covered with tin-foil, and suspended by silken strings, will answer well, when the electrophorus is wanted of a large diameter.

The under plate may be made of glass, sealing-wax, or the following composition, viz. four parts rosin, three parts pitch, three parts shell-lac, two parts Venice turpentine, melted together over a gentle fire. It may be poured and spread upon a thin linen cloth to about one-fourth of an inch thick. The linen cloth must be stretched upon a hoop, and made as tight as possible. If the surface is a little rough, it will be no worse.

The manner of using this machine is as follows: Rub the coated side of the under plate A with fine new flannel, or a hare's or cat's skin; and when it is excited as much as possible, set it on a table, and place the upper plate upon it, and put your finger on the upper plate; then remove your finger, and take hold of the top of the glass handle I, and apply it to the knob of a coated jar. Repeat this operation for 30 or 40 times, and the jar will become charged.

Cavallo mentions one of the above kind made by him, with which he charged a coated phial several times, by once exciting, so strong as to pierce a hole through a card at every discharge.

When a glass is covered with sealing-wax, after it is excited and laid with the waxed side downward, and the glass uppermost, then on making the usual experiment of puting the metal plate on it, and taking the spark, &c. it will be attended with contrary electricity to what it had before.

To explain these phenomena it will be again necessary to recur to what has been said concerning negative and positive electricity; it will be necessary also to re-

collect, that the negative electricity was originally termed the resinous, because it was first thought to be peculiar to those substances. In the electrophorus, therefore, the lower part or resinous mass, being negatively electrified, the matter is taken from the metal plate, and this becoming also negatively electrified, the fluid is attracted from any body which is presented to it.

Electrical phenomena.—The various phenomena of electricity may, for the sake of perspicuity, be divided into four classes; in the first of which may be included all those experiments which serve to illustrate the electrical attraction and repulsion; in the second, those produced by the stream of electricity; in the third class may be ranged all those phenomena which are accompanied with the luminous appearances; and lastly, we may enumerate those more formidable effects arising from the concentrated electricity, in the experiments with the Leyden phial and the electrical battery.

1. That light bodies are attracted and repelled by the electrical influence, is evident from many common experiments. If a feather of a downy kind is affixed by linen threads to a small wire, and the wire is inserted into the prime conductor, upon turning the cylinder, the plumage will be found to expand every way, and the threads will also recede as far as possible from each other. If a finger approaches the feather, the plumage will bend towards it, and if the finger is moved, the feather will seem to follow it. If a spark is taken from the conductor, the plumage immediately collapses: and, if the cylinder is again excited, the threads will diverge, and the plumage expand as before.

There is another very entertaining experiment illustrative of the electric attraction. If a small plate of metal is suspended from the prime conductor, and another plate is placed at a small distance under it; if then on the lower plate a piece of leaf gold is laid, when the cylinder is turned the gold will be lifted up, and expand itself with one corner opposite the upper and the other opposite the under plate. If the room is darkened, the leaf gold will appear to be supported by pillars of fire.

If instead of the leaf gold small figures or images (which may be easily made of thick paper or thin pasteboard, see fig. 21.) are placed on the under plate, after turning the cylinder the images will successively rise up in an erect position, and will seem to dance between the two plates, sometimes leaping upon each other, and exhibiting themselves in a variety of entertaining positions. If the head of the image is held before the fire and dried, the image will ascend to the upper plate and remain there; and if the experiment is reversed, and the feet of the image are dried, and the head a little moistened at the same time, the image will continue to stand immoveable on the lower plate. The experiment will not succeed, if instead of metal, the images are placed upon glass, because glass is an electric, and does not transmit the electrical matter, and consequently the images will not move backwards and forwards; but if the finger or any conducting body is held under the glass plate, they will then move as before.

There is another very pretty experiment illustrative of the same principle, the apparatus of which is to be found in the shops of most of the instrument-makers, and which has been already described. It consists of three small bells, with clappers between them. (See fig. 8.) If the machine is turned the clappers fly from one bell to the other, and ring a kind of peal by the effect of electricity. To explain this, it is only necessary to notice that the two outer bells are suspended by metal chains, and the middle bell and clappers by silk, but from the middle bell a chain is suspended, which goes to the table. The fluid is then conveyed from the conductor down the chains to the two exterior bells, and the clappers which are light are attracted by them. The clappers then become charged and are repelled by the outer bells, but attracted by that in the middle, to which they give the electricity they had received, and it is conveyed to the earth by the chain which communicates with the table. Being thus disburthened, they are again attracted and strike the outer bells as before, and this is continued as long as the machine is in action.

The electrical porcupine, as it has been called, is formed nearly in the shape of the animal, the name of which it bears. It is covered with ermine, or some other fur, in which are inserted some pieces of cotton pulled out to a considerable length, to resemble the porcupine's quills. On turning the machine the hairs of the fur or ermine diverge, and the pieces of cotton are discharged, and by a powerful conductor are driven to some feet distance. This effect, it is obvious, depends upon the principle which has been just explained, and is illustrative of the electric repulsion.

A very common mode of demonstrating the same effect, is to put a pointed wire into one of the holes of the conductor, and while the machine is in action, to hold a glass tumbler over the point till its interior surface becomes charged. If then a few pith-balls are laid on the table, and covered with the tumbler, the balls will presently move about as if by magical power. See fig. 22.

Electrified bodies in certain circumstances adhere so closely together, that the fact has given occasion to a new term in philosophy, and it has been called the electrical cohesion. This was pleasantly illustrated by some experiments on silk stockings, communicated to the Royal Society by Mr. Robert Symner a few years ago. Two silk stockings, the one black and the other white, had been for some time upon one leg, and were then rubbed with the hand, and both pulled off together; it appears that in this case the two stockings will adhere together in such a manner as to require a considerable force to separate them. M. Brisson, who repeated the experiment, observes, that after he had separated the white from the black stocking another phenomenon occurred; for while he held them one in each hand, suspended in the air, they swelled and puffed up as wide as if the leg had remained in them! When they were brought within ten or twelve inches of each other, they rushed upon one another, and adhered forcibly together; but this adhesion was not so great as that which took place while the stockings were one within the other. Mr. Symner supposed, that the success of this experiment depended upon the contrast between the black and white colour; but M. Brisson proves this hypothesis to be without foundation, having made the experiment by substituting for the black stocking another of a different colour, and even a white one; but he confesses, that when the experiment was made with two white silk stockings the effects

were weak in comparison. The same effects have been produced, when the stockings were one of black silk, and the other of light-coloured Angola wool.

Electrical attraction appears, however, not to be so strong in vacuo as in the open air. From several experiments of Beccaria's we learn, that if the air is thoroughly exhausted out of a glass receiver, the attraction and repulsion of electrified light bodies within the receiver become languid, and soon cease altogether.

2. That the stream of electricity is capable of producing motion in almost a similar manner to a stream of common air, will be manifest from several pleasing experiments. If a brass cross or fly, such as that in fig. 14. is placed on the conductor, when the machine is turned it will go rapidly round. If it is taken off, and held under the conductor, it will move in the same manner. If the cross, or fly, as it is called, is insulated, it will not move, because no electricity can be drawn through it either way. If a pin or any other conductor approaches it, it will however move as usual.

By means of the stream of electricity issuing from a point, many other amusing experiments have been contrived; such is the electrical orrery, showing the motion of the sun, earth, and moon.

The sun and earth go round the common centre of gravity between them in a solar year; and the earth and moon go round the common centre of gravity between them in a lunar month. These motions are represented by an electrical experiment as follows:

The ball S (fig. 23.) represents the sun, E the earth, and M the moon, connected by wires a c and b d: b is the centre of gravity between the earth and moon. These three balls and their connecting wires are hung and supported on the sharp point of a wire A, which is stuck upright in the prime conductor B of the electrical machine; the earth and moon hanging upon the sharp point of the wire c a c, in which wire is a pointed short pin, sticking out horizontally at c; and there is just such another pin at d, sticking out in the same manner, in the wire that connects the earth and the moon.

When the cylinder of the electrical machine is turned, these balls and wires are electrified; and the electrical fire, flying off horizontally from the points c and d, causes S and E to move round their common centre of gravity a, and E and M to move round their common centre of gravity b. And as E and M are light when compared with S and E, there is much less friction on the point b, than S and E make about the point a. The weights of the balls may be adjusted so, that E and M may go twelve times round b, in the time that S and E go once round a. This affords an amusing experiment in electricity; but it is so far from proving that the motions of the planets in the heavens are owing to a like cause, that it plainly proves they are not; for the real sun and planets are not connected by wires or bars of metal, and consequently there can be no such metallic points as c and d between them. And without such points, the electric fluid would never cause them to move; for, take away these points in the above-mentioned experiment, and the balls will continue at rest, let them be ever so strongly electrified.

Fig. 24 represents a water-mill for grinding corn, turned by a stream of electricity. A is the water-wheel, B the cog-wheel on its axis, C the trundle turned by that wheel, and D the running mill-stone on the top of the axis of the trundle. It may easily be contrived and turned also by electricity, if instead of the round plate D for the mill-stone, there is a horizontal wheel on the trundle C, with spur-cogs, which will turn two trundles placed on its opposite sides, and on the top of each of these trundles' axis, may be a round plate representing a mill-stone; so that this model has all the working parts of a double water-mill, turning two mill-stones.

Set the mill near the prime conductor, and place the crooked wire so that its point may be directed towards the uppermost side of the great wheel A. Then turn the glass globe by the winch, and the stream of fire that issues from the point of the wire will turn the wheel, and consequently all the other working parts of the mill.

Small boats or swans are sometimes made of light wood or cork, and they may be attracted and made to swim in any direction, by applying a finger towards them; or they may have the addition of sails, and will then be made to sail briskly before an electrical gale from a wire held in the hand of the operator.

3. Every person knows that with his knuckle or finger, he can draw sparks from a conductor; the further he removes his knuckle from the conductor, the longer will be the spark, and it will even resemble lightning in the curves it forms, and its zig-zag appearance.

There is even a mode of imitating the course of lightning by some conducting substance, such as pieces of tin-foil stuck at different distances on a plate of glass, and sending a strong spark through them from a powerful conductor. In fig. 25 is a glass tube with pieces of tin-foil pasted on at different distances in a spiral direction, and hence called the spiral tube. It is inclosed in a larger tube, fitted with brass caps at each end, which connect with the tin-foil. When the electric spark is made to pass through this tube, a beautifully illuminated spot will be seen at each separation of the tin-foil; and from the course in which the electric light is attracted, will serve to give some idea, on a very diminutive scale, of the manner in which the lightning is attracted from one cloud to another. A similar effect will be produced by the jar, fig. 26.

A very pleasing effect is also produced from the electrical light, which has been called the diadem of beatification. The person who wishes to exhibit this experiment, binds his head with a band of silvered leather; and while he stands upon an insulated stool is connected with the conductor by a metal chain. If then, while the machine is turned, another person passes his knuckle or finger near the band of leather, it will appear beautifully illuminated, and vivid flashes of light will play about the person's head who wears the magic diadem.

It has been mentioned before that spirit of wine may be set on fire by the electric spark. The experiment is easily made either by placing the ladle or spoon which contains the fluid upon the conductor, and taking the spark through the spirit; or by a person holding the spoon or ladle in one hand, while he stands on the insulated stool, having the other hand on the conductor. If then another person approaches the spoon, either with his finger or an iron poker, or other metal instrument, the spark will pass through the spirit of wine,

and set it immediately in a flame. The experiment will succeed better if the spirit is a little warm, or even if the spoon in which it is contained has been previously a little heated.

4. Whatever may be the effects, however, of a spark drawn from the conductor, they are greatly augmented by what may be termed concentrated electricity, when the fluid is accumulated by means of a Leyden phial, or a glass plate properly prepared. If a card is held close to the coating of a charged jar near the bottom, and one knob of the discharging rod is applied to the card, and the other to the ball of the jar, the electric fluid in passing through the card, will perforate it. The edges of the hole on each side will be a little raised, and the discharge will be attended with a sulphureous smell. With a moderate battery a quire of the thickest paper may be perforated in the same manner.

If a small chain is laid upon a piece of white paper, and a shock from a Leyden phial is made to pass through it, the paper will be stained with a blackish tinge at every joint of the chain; and if the experiment is made in the dark, the chain will appear illuminated, with a kind of radiation at every juncture.

By a strong shock of electricity, metals are melted, and gold itself may be incorporated with glass, so as to give the latter the colour and appearance of that metal. The experiment is not difficult. All that is required is, to take two narrow slips of common window-glass, each about an inch broad, and three or four inches long. Let a narrow slip of gold leaf then be placed between the glasses, with about an inch at each end hanging beyond the glasses, which by some means should be pressed closely together. One end of the slip of gold leaf should communicate with the outer coating of the phial; and when it is charged, one knob of the discharging rod must be applied to the other end of the leaf, so as to send the charge through it. When the glasses are taken asunder, it will be found that the gold has been melted, and the substance of it actually incorporated with the glass, which consequently must have undergone a partial fusion itself.

By a smart shock of electricity from a charged phial, or a battery, a plant may be killed, and the experiment will best succeed with the common balsam or impatiens. The smaller animals may also be deprived of life; but human art has not yet been able to construct a battery large enough to kill an animal above the size of a sheep or a dog. The immediate or proximate cause of the death of animals by electricity, or by lightning, which is natural electricity, has not yet been ascertained. It was once supposed that the living principle was extinguished by the bursting of some blood vessel, from the violence of the shock; but a dog which was killed by lightning, was carefully dissected, and none of the vessels found in the least injured. Beccaria recovered some persons apparently struck dead by lightning; and when questioned with respect to the pain or suffering which they endured, they only complained of an unusual numbness or weariness in their limbs. The flesh of animals killed by electricity is rendered extremely tender, and is recommended by Dr. Franklin as an article of luxury. It will also putrify in a much shorter time than the flesh of those which are killed in any ordinary way.

Electricity augments the natural evaporation of fluids, and especially of those fluids which are most subject to evaporation of themselves; and it has a greater effect on fluids, when the vessels containing them are non-electrics. If a humid body, a sponge for instance, is placed upon a conductor positively electrified, the evaporation will proceed much more rapidly, and it will be much sooner dry, than a similar body differently circumstanced.

Dr. Priestley also supposes that plants, when electrified, vegetate earlier and more vigorously, than those which have not been subjected to this influence.

That electricity increases the insensible perspiration of animals, may be inferred from the circumstance that electrified animals are always lighter than those which are not.

The stream of electrical fluid has no sensible heat, but even appears cold to the touch; yet we have seen that the more inflammable bodies, and particularly spirit of wine, may be ignited by it; in this respect it remarkably differs from fire or caloric.

The luminous effects of electricity are not the same in vacuo as in the air, and the reason of this is, that dry air is a non-conductor. Thus if a wire with a round end is included in an exhausted receiver, and presented to a conductor of an electrical machine, every spark will pass through the vacuum in a broad stream of light, visible the whole length of the receiver, moving with regularity (unless it is turned back by some non-electric); and then dividing itself into a number of beautiful rivulets, which are continually separating and uniting in a pleasing manner. When the vessel is grasped by the hand, a pulsation is perceived like that of an artery, and the fire inclines towards the hand. A small quantity of air is, however, necessary to occasion the most brilliant luminous effect.

Of thunder and lightning, meteors, water-spouts, &c.—It no longer remains a doubt among philosophers, that the cause of thunder is the same with that which produces the ordinary phenomena of electricity: the resemblance between them is indeed so great, that we cannot believe thunder itself to be any other than a grander species of electricity, naturally excited without the feeble efforts of human art. This fluid, probably, is diffused through the whole atmosphere at all times, either in a smaller or greater degree; and is occasionally perceptible to our senses, according to the concurrence of natural circumstances.

The cloud which produces the thunder and lightning may be considered as a great electrified body; but how has the cloud acquired its electric virtue? is the reasonable demand of an inquisitive mind: and to satisfy this inquiry it will be necessary to refer to what has been before observed, that this power is produced in two modes, by friction, and by communication. Bodies electrified by friction communicate their virtue to other bodies which are susceptible of it, provided they are insulated, and at a convenient distance. As air, therefore, is an idio-electric body, it is not unphilosophical to suppose, that in stormy weather, especially when it is common to observe the clouds and the wind to take contrary courses, a part of the atmosphere, rushing by the other, may cause the air to be electrified by the friction of its

own particles, or by rubbing against terrestrial objects which it meets in its passage, or perhaps against the clouds themselves. It is probable also, that the inflammable substances, which arise and accumulate in the cloudy regions, contribute to increase the effects, not only of themselves, but perhaps still more by the electric matter which they carry along with them. Another circumstance, which favours this inference, is, that thunder-storms are more frequent and tremendous in those times and places, when and where we have reason to conclude that these exhalations are in the greatest abundance in the atmosphere, as in warm seasons and climates, as well as in those places where the earth is filled with substances capable of furnishing a large quantity of these exhalations, and in particular in the neighbourhood of volcanoes.

A cloud in a thunder-storm may be considered as a great conductor, actually insulated and electrified; and it may be supposed to have the same effect upon those non-electrics which it meets with in its course, as our common conductors have upon those which are presented to them. If a cloud of this kind meets with another which is not electrified, or less so than itself, the electric matter flies off from all parts towards this cloud; hence proceed flashes of lightning, and the formidable report of thunder.

"Thunder-storms," says Beccaria, "generally happen when there is little or no wind; and their first appearance is marked by one dense cloud, or more, increasing very fast in size, and rising into the higher regions of the air; the lower surface black, and nearly level, but the upper finely arched, and well defined. Many of these clouds seem frequently piled one upon another, all arched in the same manner; but they keep continually uniting, swelling, and extending their arches.

"At the time of the rising of this cloud, the atmosphere is generally full of a great number of separate clouds, motionless, and of odd and whimsical shapes. All these, upon the appearance of the thunder cloud, draw towards it, and become more uniform in their shapes as they approach, till coming very near the thunder cloud, their limbs mutually stretch towards one another; they immediately coalesce, and together make one uniform mass. But sometimes the thunder cloud will swell, and increase very fast, without the conjunction of these adscititious clouds, the vapours of the atmosphere forming themselves into clouds wherever it passes. Some of the adscititious clouds appear like white fringes at the skirts of the thunder cloud, but these keep continually growing darker and darker as they approach or unite with it.

"When the thunder cloud is grown to a great size, its lower surface is often ragged, particular parts being detached towards the earth, but still connected with the rest. Sometimes the lower surface swells into various large protuberances, bending uniformly towards the earth. When the eye is under the thunder cloud, after it is grown larger, and well formed, it is seen to sink lower, and to darken prodigiously; at the same time that a number of adscititious clouds (the origin of which can never be perceived) are seen in a rapid motion, driving about in very uncertain directions under it. While these clouds are agitated with the most rapid motions, the rain generally falls in the greatest plenty; and if the agitation is exceedingly great, it commonly hails.

"While the thunder cloud is swelling, and extending its branches over a large tract of country, the lightning is seen to dart from one part of it to another, and often to illuminate its whole mass. When the cloud has acquired a sufficient extent, the lightning strikes, between the cloud and the earth, in two opposite places, the path of the lightning lying through the whole body of the cloud and its branches. The longer this lightning continues, the rarer the cloud grows, and the less dark is its appearance, till at length it breaks in different places, and displays a clear sky."

It is the opinion of the same author, that the clouds serve as conductors to convey the electric fluid from those parts of the earth which are overloaded with it, to those which are exhausted of it.

To prove that the earth is often positively charged with respect to the clouds in one part while it is negative in another, he adverts to the fall of great quantities of sand, and other light substances, which are often carried into the air, and scattered uniformly over a large tract of country, when there is no wind to effect this phenomenon; and even when there was, they have been carried against the wind; he therefore supposes, that these light bodies are raised by a large quantity of electrical matter issuing from the earth.

This comparatively rare phenomenon, he thinks, exhibits both a perfect image and demonstration of the manner in which the vapours of the atmosphere are raised to form thunder clouds. The same electric matter, wherever it issues, attracts to it, and carries into the higher regions of the air, the watery particles dispersed in the atmosphere. The electric matter ascends, being solicited by the less resistance it finds there than in the common mass of the earth, which at those times is generally very dry, and consequently highly electric. The uniformity with which thunder clouds spread themselves, and swell into arches, must be owing to their being affected by some cause which, like the electric matter, diffuses itself uniformly wherever it acts, and to the resistance they meet with in ascending through the air.

The same cause which first raised a cloud from vapours dispersed in the atmosphere, draws it to those already formed, and continues to form new ones, till the whole collected mass extends so far as to reach a part of the earth where there is a deficiency of electric fluid; thither also they will be attracted, and thus the mass serves as a conductor. When the clouds are attracted in their passage by those parts of the earth, where there is a deficiency of the fluid, those detached fragments are formed, and also those uniform depending protuberances, which are probably the cause of water-spouts.

A wind always blows from the place whence a thunder cloud proceeds; and the wind is more or less violent in proportion to the sudden appearance of the thunder cloud, the rapidity of its expansion, and the velocity with which the adscititious clouds join it. The sudden condensation of such a prodigious quantity of vapour must displace the air, and agitate it on all sides.

In three states of the air, says the author above quoted, I could find no electricity in it. 1st. In windy weather. 2d. When the sky was covered with distinct and

black clouds, which had a slow motion. 3d. In moist weather, not actually raining.

In rainy weather, without lightning, his apparatus was always electrified a little time before the rain fell, and during the time of rain, but ceased a little before the rain was over.

The higher his rods reached, or his kites flew, the stronger signs they gave of being electrified.

It has been intimated that the clouds are sometimes positively, and sometimes negatively electrified. In the latter case, the lightning is supposed, upon the Franklinean theory, to proceed from the earth to the cloud. The general effects of lightning are precisely the same with those of the electric shock, only greatly magnified. It may not be improper in this place to notice an old error, namely, the melting of metals by what has been called the cold fusion. The error is found to rest upon certain ill-attested relations of swords being melted in the scabbard, by lightning, and money in a bag, without injuring the scabbard or the bag. A variety of experiments have been accurately made to determine the fact; the results of which have been, that the thin edge of the sword, or of the money, might have been instantaneously melted, and yet so instantaneously cooled, as neither to affect the scabbard nor the bag. A very small wire will instantly melt and instantly cool in the flame of a common candle.

Mr. Kinnesley inclosed a small wire in a goose quill filled with loose grains of gunpowder, which took fire as readily as if they had been touched by a red-hot poker; tinder was kindled when tied to a piece of the same wire; but no such effects could be produced with a wire twice as large. Hence it appears, as Mr. Kinnesley remarks, that though the electrical matter has no sensible heat when in a state of rest, it will, in passing through bodies, produce heat in them, provided they are proportionably small. Thus, in passing through the small wire, the particles are confined to a narrower passage, and, crowding close together, act with a more condensed force, and produce sensible heat.

The discovery of Dr. Franklin, which established the identity of lightning with the electrical fluid, suggested an invention, for which we are indebted to the same philosopher, for securing buildings from this most formidable enemy. The reader will perceive that we allude to that of metallic conductors.

The effects of the electric matter, when it strikes a building, and the method of preventing it, are exemplified by an instrument called the thunder-house, representing the side of a house, either furnished with a metallic conductor, or not. A (figure 27) is a board about three quarters of an inch thick, and shaped like the gable-end of a house. This board is fixed perpendicularly upon the bottom board B, upon which the perpendicular glass pillar C is also fixed, in a hole about eight inches distant from the basis of A. A small hole I L M K, about a quarter of an inch deep, and nearly one inch wide, is made in the board A, and is filled with a square piece of wood, nearly of the same dimensions. It should be merely of the same dimensions, because it must go so easily into the hole that it may drop off by the least shaking of the instrument. A wire I K, is fastened diagonally to this square piece of wood. Another wire L H, of the same thickness, having a brass ball H screwed on its pointed extremity, is fastened on the board A; so also the wire M N, which is shaped in a ring at N. From the upper extremity of the glass pillar C, a crooked wire proceeds, having a spring socket F, through which a double knobbed wire slips perpendicularly, the lower knob G of which falls just above the knob H. The glass pillar C must not be made very fast in the bottom board; but it must be fixed so that it may be easily moved round its own axis, by which means the brass ball G may be brought either nearer or farther from the ball H, without touching the part E F G. Now, when a square piece of wood L M I K (which may represent the shutter of a window or the like) is fixed into the hole, so that the wire I K stands in the direction L M, then the metallic communication from H to N is complete, and the instrument represents a house furnished with a proper metallic conductor; but if the square piece of wood L M I K is fixed so that the wire I K stands in the direction I K as represented in the figure, then the metallic conductor H N from the top of the house to its bottom, is interrupted at L M: in which case the house is not properly secured.

Fix the piece of wood L M I K, so that its wire may be as represented in the figure, in which case the metallic conductor H N is discontinued. Let the ball G be fixed at about half an inch perpendicular distance from the ball H: then, by turning the glass pillar C, remove the former ball from the latter; by a wire or chain, connect the wire E F with the wire Q of the jar P, and let another wire or chain, fastened to the hook N, touch the outside coating of the jar. Connect the wire Q with the prime conductor, and charge the jar: then, by turning the glass pillar C, let the ball G come gradually near the ball H, and when they are arrived sufficiently near one another, you will observe that the jar explodes, and the piece of wood L M I K is pushed out of the hole to a considerable distance from the thunder-house. Now the ball G in this experiment, represents an electrified cloud, which, when it is arrived sufficiently near the top of the house A, the electricity strikes; and as the house is not secured with a proper conductor, the explosion breaks part of it, *i. e.* knocks off the piece of wood I M.

Repeat the experiment with only this variation, viz. that this piece of wood I M is situated so that the wire I K may stand in the situation L M, in which case the conductor H N is not discontinued; and you will observe, that the explosion will have no effect upon the piece of wood L M, this remaining in the hole unmoved; which shows the usefulness of the metallic conductor.

Further, unscrew the brass ball H from the wire H L, so that this may remain pointed, and with only this difference in the apparatus, repeat both the above experiments; and you will find the piece of wood L M is in neither case moved from its place, nor will any explosion be heard.

The conductor E F G in this experiment is supposed to represent a thunder cloud discharging its contents on a weathercock, or any other metal, at the top of a building; and it may be inferred from this experiment, that if there is a connection of metal to conduct the electric fluid down to the earth, the building will receive no da-

mage; but where the connection is imperfect, it will strike from one part to another, and thus endanger the whole building.

Elevated conductors, applied to buildings to secure them from lightning, will in this manner discharge the electricity from a cloud that passes over them, and a greater quantity of the discharge will pass through a pointed conductor than through one which terminates with a ball; but whether the discharge will be made by a gradual current, or by explosion, will depend upon the suddenness of the discharge, or the nearness and motion of the cloud, and the quantity of the electricity contained in it. If a small cloud hangs suspended under a large one loaded with electric matter, pointed conductors on a building underneath will receive the discharge by explosion, in preference to those terminated by balls; the small cloud forming an interruption, which allows only an instant of time for the discharge.

Earl Stanhope has communicated to the public, in a treatise on this subject, some essentials to be observed in the erection of conductors to buildings: he advises, that the upper fifteen or twenty inches of the rod should be composed of copper and not of iron, as the latter being exposed to the weather will rust, and rust does not conduct electricity; that the iron part of the rod should be painted, but not the upper part of it, because paint is no conductor. He further advises, that the upper extremity of a conducting rod should not only be accurately pointed and finely tapered, but that it should be extremely prominent, about ten or fifteen feet above all the parts of the building which are the nearest it. It may be added, that a conductor should always be carried in the earth some feet beyond the foundation of the building, and should, if possible, terminate in water.

The safest situation during a thunder storm is the cellar; for when a person is below the surface of the earth, the lightning must strike it before it can reach him, and will, in all probability, be expended on it. Dr. Franklin advises persons apprehensive of lightning to sit in the middle of a room, not under a metal lustre or any other conductor, and to lay their feet up upon another chair. It will be still safer, he adds, to lay two or three beds or matrasses in the middle of the room, and folding them double, to place the chairs upon them. A hammock suspended by silk cords would be an improvement upon this apparatus. Persons in fields should prefer the open parts to the vicinity of trees, &c. The distance of a thunder storm, and consequently the danger, are not difficult to be estimated. As light travels at the rate of 72,420 leagues in a second of time, its effects may be considered as instantaneous within any moderate distance. Sound, on the contrary, is transmitted only at the rate of 1,142 feet, or about 380 yards in a second. By accurately observing therefore the time which intervenes between the flash and the noise of thunder which follows it, a very near calculation may be made of its distance, and we know no better means of removing unnecessary apprehensions.

The success of Dr. Franklin, in ascertaining the cause of thunder and lightning, induced succeeding philosophers to apply the same theory to the explanation of the other atmospherical phenomena. From a number of observations, the indefatigable Beccaria endeavours to account for the rising of vapours and the fall of rain, upon electrical principles; and it must be confessed, that if it is not a primary agent in these effects, it would be rashness entirely to deny its influence. This philosopher supposes, that previously to rain a quantity of electric matter escapes from the earth, and in its ascent to the higher regions of the air collects and conducts into its path a great quantity of vapours. The same cause that collects will condense them more and more, till in the places of the nearest intervals they come almost into contact, so as to form small drops, which, uniting with others as they fall, come down in rain. The rain he supposes to fall heavier in proportion as the electricity is more vigorous.

Hail he supposes to be formed in the higher regions of air, where the cold is intense, and where the electric matter is very copious. In these circumstances, a great number of particles of water are brought near together, where they are frozen, and in their descent collect other particles; so that the density of the substance of the hailstone grows less and less from the centre, this being formed first in the higher regions, and the surface being collected in the lower. Agreeably to this, it is observed, that on mountains, hailstones as well as drops of rain are very small, there being but a small space through which they can fall.

Clouds of snow differ in nothing from clouds of rain, but in the circumstance of the cold which freezes them. Both the regular diffusion of snow, and the regularity of the parts of which it consists, show the clouds of snow to be actuated by some uniform cause like electricity.

Consistent with this theory is the fact, that vapours never rise to a great height without producing meteors. Almost all volcanic eruptions are accompanied with lightning. The column of vapour, which proceeds from the bowels of a volcano, is continually transversed by lightning, which sometimes seems to proceed from the higher regions, sometimes from the column itself. These lightnings were observed by the younger Pliny, in the eruption which killed his uncle; and sir William Hamilton has observed them several times. The aurora borealis is also generally supposed to be electrical; its light seems to be produced by the electric fluid, while it is condensed in passing in the columns of elevated vapour.

Mr. Adams's description of this meteor, in his Lectures, is as follows: The appearances of the aurora come under four different descriptions. 1st, A horizontal light, like the morning aurora, or break of day. 2dly, Fine, slender, luminous beams, well defined, and of dense light. These often continue a quarter, a half, or a whole minute, apparently at rest, but oftener with a quick lateral motion. 3dly, Flashes pointing upward, or in the same direction with the beams, which they always succeed. These are only momentary, and have no lateral motion; but they are generally repeated many times in a minute. They appear much broader, more diffuse, and of a weaker light, than the beams: they grow gradually fainter till they disappear; and sometimes continue for hours, flashing at intervals. 4thly, Arches, nearly in the form of a rainbow: these, when complete, go quite across the heavens, from one point of the horizon to the opposite point.

When an aurora happens, these appearances seem to

succeed each other in the following order: 1, the faint rainbow-like arches; 2, the beams; and, 3, the flashes. As for the northern horizontal light, it appears to consist of an abundance of flashes or beams blended together by the situation of the observer.

The beams of the aurora borealis appear at all places to be arches of great circles of the sphere, with the eye in the centre; and these arches, if prolonged upwards, would all meet at one point.

The rainbow-like arches all cross the magnetic meridian at right angles. When two or more appear at once, they are concentric, and tend to the east and west; also the broad arch of the horizontal light tends to the magnetic east and west, and is bisected by the magnetic meridian; and when the aurora extends over any part of the hemisphere, whether great or small, the line separating the illuminated part of the hemisphere from the clear part, is half the circumference of a great circle crossing the magnetic meridian at right angles, and terminating in the east and west: moreover, the beams perpendicular to the horizon, are only those on the magnetic meridian.

That point in the heavens to which the beams of the aurora appear to converge, at any place, is the same as that to which the south pole of the dipping-needle points at that place.

The beams appear to rise above each other in succession; so that of any two beams, that which has the higher base has also the higher summit.

Every beam appears broadest at or near the base, and to grow narrower as it ascends; so that the continuation of the bounding lines would meet in the common centre to which the beam tends.

The height of the rainbow-like arches of the aurora is estimated by Mr. Dalton to be above the earth's surface about 150 English miles.

A very beautiful experiment will illustrate this appearance in the heavens: Fig. 28 is called the luminous conductor. A is a glass tube about two feet long, capped at both ends with brass, having one of the ends furnished with a stop-cock, and a screw to fit into the plate of the air-pump. This tube is exhausted of air, and when it is placed in the circuit of the electric fluid, by fixing a chain to each end, which is connected with the positive and negative parts of the machine, the electricity in passing through it, exhibits a beatiful luminous appearance, very much resembling the aurora borealis. See AURORA BOREALIS.

It was intimated that water-spouts are among the phenomena which some philosophers have attempted to explain on electrical principles. A water-spout is a most formidable phenomenon, and is indeed capable of causing great ravages. It commonly begins by a cloud, which appears very small, and which mariners call the squall; which augments in a little time into an enormous cloud of a cylindrical form, or that of a reversed cone, and produces a noise like an agitated sea; sometimes emitting thunder and lightning, and also pouring down large quantities of rain or hail, sufficient to inundate large vessels, overset trees and houses, and every thing which opposes its violent impetuosity.

These water-spouts are more frequent at sea than by land; and sailors are so convinced of their dangerous consequences, that when they perceive their approach, they frequently endeavour to break them by firing a cannon before they approach too near the ship. They have also been known to have committed great devastations by land: though, where there is no water near, they generally assume the harmless form of a whirlwind. See WATERSPOUT, and METEOROLOGY.

In accounting for these phenomena upon electrical principles, it is observed, that the effluent matter proceeds from a body actually electrified, towards one which is not so; and affluent matter proceeds from a body not electrified, towards one which is actually so. These two currents occasion two motions analogous to the electrical attraction and repulsion. If the current of the effluent matter is more powerful than of the affluent matter, which in this case is composed of particles exhaled from the earth, the particles of vapours, which compose the cloud, are attracted by this effluent matter, and form the cylindrical column called the descending water-spout; if, on the contrary, the affluent matter is the strongest, it attracts a sufficient quantity of aqueous particles to form gradually into a cloud, and this is commonly termed the ascending water-spout.

Of the electricity which is produced by means of melting, heating, cooling, and evaporation.—If sulphur is melted in an earthen vessel, and the whole is left to cool upon conductors; and if afterwards the sulphur, when cold, is taken out of the vessel, it will be found strongly electrical; but not at all so if it is left to cool upon electrics.

If sulphur is melted in a glass vessel, and is left to cool, both the glass and the sulphur will acquire a strong electricity, the former positive and the latter negative; and that will be the case whether they are left to cool upon electrics or upon conductors.

If melted sulphur is poured into a vessel of baked wood, it will acquire the negative, and the wood the positive, electricity; but if it is poured into sulphur, or rough glass, it will acquire no sensible degree of electricity.

Melted sulphur poured into a metal cup, and there left to cool, shows no signs of electricity whilst standing in the cup; but if they are separated, then they will both appear strongly electrified, the sulphur positive, and the cup negative. If the sulphur is replaced in the cup, every sign of electricity will vanish; but if, whilst separate, the electricity either of the cup or sulphur is taken off, then on being replaced they both will appear possessed of that electricity which has not been taken off.

Melted wax, being poured into glass or wood, acquires the negative electricity, and the glass or wood becomes positive. But sealing-wax, poured into a sulphur vessel, acquires the positive electricity, and leaves the sulphur negative.

Chocolate fresh from the mill, as it cools in the tin pans in which it is received, becomes strongly electrical. When turned out of the pans, it retains this property during a certain time, but loses it presently by handling. By melting it again in an iron ladle, and pouring it into the tin pans as at first, you may renew its power once or twice; but when the mass becomes very dry and powdery in the ladle, the electricity is no longer received by simple melting; but if then a little olive oil is added, and is mixed well with the chocolate

in the ladle, and is afterwards poured into the tin pans as at first, it will be found to have completely recovered its electrical power, which continues a considerable time.

The property of becoming electrified merely by heating or cooling, was first observed in, and is eminently possessed by, a hard pellucid stone called the tourmalin, which is generally of a deep red, or purple, or brown colour; which seldom, if ever, exceeds the size of a small walnut; and which is found in several parts of the East Indies, especially in the island of Ceylon; but on farther examination it has been found that several other precious stones, and especially the Brasilian emerald, possess the like properties more or less; hence the following particulars, which have been principally observed of the tourmalin, must be understood to belong likewise to most other precious stones.

1. The tourmalin, while kept in the same temperature, shows no signs of electricity; but it will become electrical by increasing or diminishing its heat, and stronger in the latter circumstance than in the former. A very trifling alteration of temperature is often sufficient to produce the effect.

2. Its electricity does not appear all over its surface, but only on two opposite sides of it, which may be called its poles, and which always are in one right line with the centre of the stone, and in the direction of its strata; in which direction the stone is absolutely opaque, though in the other it is semitransparent.

3. Whilst the tourmalin is heating, one of its sides (call it A) is electrified plus, or positive, and the other B minus; but when cooling, A is minus, and B is plus. Hence, if one side of the stone is heating, whilst the other is cooling, then both sides will acquire the same electricity; or if one side only changes its temperature, then that side only will appear electrified.

4. If this stone is heated, and suffered to cool without either of its sides being touched, then A will appear positive, and B negative, all the time of its heating and cooling.

5. This stone may be excited by means of friction like any other electric; and either of its sides, or both, may be rendered positive.

6. If the tourmalin is heated or cooled upon some other insulated body, that body will be found electrified as well as the stone; but it will be found possessed of the electricity contrary to that of the contiguous side of the stone.

7. The electricity of either side, or of both, may be reversed by heating or cooling the tourmalin in contact with various substances, such as the palm of the hand, a piece of metal, &c.

8. These properties of the tourmalin are also observable in vacuo, but not so strong as in the open air.

9. If a tourmalin is cut into several parts, each piece will have its positive and negative poles, corresponding to the positive and negative sides of the original stone.

10. If this stone is covered all over with some electric substance, such as sealing-wax, oil, &c. it will in general show the same properties as without it.

11. A vivid light appears upon the tourmalin, whilst heating in the dark, and by a little attention one may be easily enabled by this light to distinguish which side of the stone is positive, and which negative. Sometimes when the stone is strongly excited, pretty strong flashes may be seen in the dark, to go from the positive to the negative side of it.

12. Lastly, it has been found that with respect o the electric properties, the tourmalin is sometimes injured by the action of a strong fire, at other times is improved, and sometimes is not at all altered by it.

The evaporation of water, as also of some other fluids, produces electricity; viz. those bodies from which the water has departed, will remain in a negative state of electricity, indicating that the water by its conversion into vapour has its capacity for the electric fluid increased, as it has its capacity increased for containing heat. But though the effect is in general such as has been mentioned above, yet there are two exceptions which involve the subject in some difficulty, and which will require farther experiments and consideration.

The exceptions are, 1st, that if water is evaporated by being put in contact with a red-hot piece or pieces of very rusty iron, it will leave the iron electrified positively; whereas, if the iron is not rusty, the evaporation of the water from its surface will leave it electrified negatively. 2dly. If water is evaporated by throwing into it impure red-hot glass (such as the green glass of common bottles), the vessel, or the remaining water, will be electrified positively.

This curious production of electricity by evaporation, as also the production of electricity by the condensation of vapour, may be easily observed in the following manner:

Place a metallic cup, or a pewter plate, upon an insulating stand, and connect a sensible electrometer (fig. 18) with it. Also place one or two lighted coals in the cup or plate; then pour a little water at once upon the coal or coals, which will produce a quick evaporation accompanied with a great hissing noise, and at the same time the electrometer will diverge with negative electricity.

If the steam which issues copiously from water quickly boiling, is received under a pretty large and insulated metallic plate, that plate, by the condensation of the steam upon it, will be electrified positively, as may be ascertained merely by connecting a sensible electrometer with it.

On throwing a variety of other substances upon actually burning, or only hot and insulated coals, the coals, &c. either showed negative electricity, or no electricity at all. Either spirit of wine, or ether, when thus treated, left the coals negative; but if (the coals being sufficiently hot) the spirit of wine or the ether took fire, and burned in their usual way, then no electricity was produced.

Of animal electricity.—Under this title we shall take notice of that electricity only which is produced from the animal itself, in consequence of its particular organization, and not that which is produced by the application of metallic substances to animals.

Three fishes have hitherto been discovered to have, whilst living, the singular property of giving shocks analogous to those of artificial electricity; namely, the torpedo, the gymnotus electricus, and the silurus electricus. Those animals belonging to three different or-

ders of fish; and the few particulars which they seem to have in common are the power of giving the shock; an organ in their bodies, called the electric organ, which is in all probability employed by those animals for the exertion of that power; a smooth skin without scales; and some spots here and there on the surface of their bodies.

The torpedo, which belongs to the genus of rays (raja electrica), is a flat fish, very seldom 20 inches long; weighing not above a few pounds when full-grown, and is pretty common in various parts of the sea-coast of Europe. The electric organs of this animal are two in number, and are placed on each side of the cranium and gills, reaching from that place as far as the semicircular cartilages of each great fin, and extending longitudinally from the anterior extremity of the animal to the transverse cartilage which divides the thorax from the abdomen. In those places they fill up the whole thickness of the animal from the lower to the upper surface, and are covered by the common skin of the body, under which, however, are two thin membranes or fasciæ. The length of each organ is less than one-third part of the whole length of the animal. Each organ consists of perpendicular columns, reaching from the under to the upper surface of the body, and varying in length according to the various thickness of the fish in various parts. The number of these columns is not constant, differing in different torpedos, and likewise in different ages of the animal. In a very large torpedo, one electric organ was found to consist of 1182 columns. The greatest number of those columns are either irregular hexagons, or irregular pentagons, but their figure is by no means constant. The diameters are generally equal to one-fifth part of an inch.

The above-mentioned electric organs seem to be the only parts employed to produce the shock; the rest of the animal appearing to be merely the conductor of that shock, as parts adjacent to the electric organs; and, in fact, the animal has been found to be a conductor of artificial electricity. The two great lateral fins, which bound the electric organs laterally, are the best conductors.

If the torpedo, while standing in water, or out of the water, but not insulated, is touched with one hand, it generally communicates a trembling motion, or slight shock, to the hand; but this sensation is felt in the fingers of that hand only. If the torpedo is touched with both hands at the same time, one hand being applied to its under, and the other to its upper surface, a shock in that case will be received, which is exactly like that which is occasioned by the Leyden phial. When the hand touches the fish on its opposite surfaces, and just over the electric organs, then the shock is the strongest; but if the hands are placed upon other parts of the opposite surface, the shocks are somewhat weaker; and no shock at all is felt when the hands are both placed upon the electric organs of the same surface; which shows that the upper and lower surface of the electric organs are in opposite states of electricity, answering to the plus and minus sides of a Leyden phial. When the fish is touched by both hands on the same surface, and the hands are not placed exactly on the electric organs, a shock, though weak, is still received; but in this case the opposite power of the other surface of the animal seems to be conducted over the skin.

The shock which is given by the torpedo, when standing in air, is about four times as strong as when standing in water; and when the animal is touched on both surfaces by the same hand, the thumb being applied to one surface, and the middle finger to the opposite surface, the shock is felt much stronger than when the circuit is formed by the application of both hands. Sometimes the torpedo gives the shocks so quickly one after the other, that scarcely two seconds elapse between them; and when, instead of a strong determinate shock, it communicates only a torpor, that sensation is naturally attributed to the successive and quick discharge of a great many consecutive shocks.

This power of the torpedo is conducted by the same substances which conduct artificial electricity, and is intercepted by the same substances which are non-conductors of electricity; hence, if the animal, instead of being touched immediately by the hands, is touched by non-electrics, as wires, wet cords, &c. held in the hands of the experimenter, the shock will be communicated through them. The circuit may also be formed by several persons joining hands, and the shock will be felt by them all at the same time. If, when the animal is in water, the hands are put in the same water, a shock will also be felt, which will be stronger if one of the hands touches the fish, whilst the other is kept in the water at a distance from it. In short, the shock of this animal is conducted by the same conductors as that of the Leyden phial; thus it may pass through more than one circuit at the same time, or the circuit may be much extended, &c. but in those cases the shock is much weakened.

The shock of the torpedo cannot pass through the least interruption of continuity; thus it will not be conducted by a chain, nor will it pass through the air from one conductor to the other, when the distance is even less than the 200th part of an inch; consequently no spark was ever observed to accompany it.

No electric attraction or repulsion was ever observed to be produced by the torpedo, nor indeed by any of the electric fishes, though several experiments have been instituted expressly for that purpose.

These shocks of the torpedo seem to depend on the will of the animal; for each effort is accompanied with a depression of its eyes, by which even his attempts to give it to non-conductors may be observed. It is not known whether both electric organs must always act together, or one of them only may be occasionally put in action by the will of the animal.

Almost all these effects of the torpedo may be imitated by means of a large electrical battery weakly charged.

The gymnotus electricus has been frequently called electrical-eel, on account of its bearing some resemblance to the common eel. The gymnotus electricus is found pretty frequently in the great rivers of South America. Its usual length is about three feet, but some of them have been said to be so large as to be able to strike a man dead with their electric shock. A few of these animals, about three feet long, were brought

alive to England thirty or forty years ago, and a great many experiments were made with them.

A gymnotus of three feet in length generally is between 10 and 14 inches in circumference at the thickest part of its body. The electric power of this animal being much greater than that of the torpedo, its electric organs are accordingly a great deal larger; and indeed that part of its body which contains most of the animal parts that are common to the same order of fishes, is considerably smaller than that which is subservient to the electric power, though the latter must naturally derive nourishment and action from the former. The head of the animal is large, broad, flat, smooth, and impressed with various small holes. The mouth is rather large, but the jaws have no teeth, so that the animal lives by suction, or by swallowing the food entire. The eyes are small, flattish, and of a blueish colour, placed a little way behind the nostrils. The body is large, thick, and roundish, for a considerable distance from the head, and then diminishes gradually. The whole body, from a few inches below the head, is distinguished into four longitudinal parts, clearly divided from each other by lines. The carina begins a few inches below the head, and widening as it proceeds, reaches as far as the tail, where it is thinnest. It has two pectoral fins; and the anus is situated on the under part, more forward than those fins, and of course not far distant from the rostrum.

This animal has two pairs of electric organs, one pair being larger than the other, and occupying most of the longitudinal parts of the body. They are divided from each other by peculiar membranes.

The nerves which go to the electric organs of the gymnotus, as well as of the torpedo, are much larger than those which supply any other part of the body. The electric organs of the gymnotus are supplied with nerves from the spinal marrow, and they come out in pairs between the vertebræ of the spine.

The gymnotus possesses all the electric properties of the torpedo, but in a superior degree. His shock is conducted by conductors of electricity; it is communicated through water, &c. The strongest shock is received when, the animal standing out of the water, you apply one hand towards the tail, and the other towards the head of the animal. In this manner shocks may be received from one of those animals, which are felt not only in the arms, but very forcibly even in the chest. If the animal is touched with one hand only, then a kind of tremor is felt in that single hand; which, though stronger, is however perfectly analogous to that which is given by the torpedo when touched in the like manner.

This power of the gymnotus is likewise depending on the will of the animal, so that sometimes he gives strong shocks, and at other times very weak ones. He gives the strongest shocks when provoked by being frequently and roughly touched.

When small fishes are put into the water where the gymnotus is, they are commonly stunned, and are either effectually or apparently killed.

The strongest shocks of the gymnoti which were exhibited in London, would pass through a very short interruption of continuity in the circuit. They could be conveyed by a short chain when stretched, so as to bring the links into a more perfect contact. When the interruption was formed by an incision made with a pen-knife on a slip of tin-foil that was pasted upon glass, the shock in passing through that interruption, showed a small but vivid spark, plainly visible in a dark room.

This animal showed a peculiar property, namely, that of knowing when he could, and when he could not, give the shock; for if non-conductors or interrupted circuits were placed in the water, he would not approach them; but as soon as the circuit was completed, he would approach the extremities of that circuit, and immediately give the shock.

The third fish which is known to have the power of giving the shock, is found in the rivers of Africa; but we have a very imperfect account of its properties.

This animal belongs to the genus which the naturalists call siluris; hence its name is siluris electricus. The length of some of these fishes has been found to exceed 20 inches.

The body of the siluris electricus is oblong, smooth, and without scales; being rather large, and flattened towards its anterior part. The eyes are of a middle size, and are covered by the skin, which envelopes the whole head. Each jaw is armed with a great number of small teeth. About the mouth it has six filamentous appendices, viz. four from the under lip, and two from the upper; the two external ones, or farthermost from the mouth on the upper lip, are the longest. The colour of the body is greyish, and towards the tail it has some blackish spots.

The electric organ seems to be towards the tail, where the skin is thicker than on the rest of the body; and a whitish fibrous substance, which is probably the electric organ, has been distinguished under it.

It is said that the siluris electricus has the property of giving a shock or benumbing sensation, like the torpedo, and that this shock is communicated through substances that are conductors of electricity. No other particular seems to be known concerning it.

Nature seems to have given these fishes the singular power of giving the shock for the purpose of securing their prey, by which they must subsist; and perhaps likewise for the purpose of repelling larger animals, which might otherwise annoy them. The power with which they are endued seems more to correspond with Galvanism (which is doubtless a species of electricity) than with common electricity. See GALVANISM.

The ancients considered the shocks of the torpedo as capable of curing various disorders; and a modern philosopher will hardly hesitate to credit their assertions, since electricity has been found to be an useful remedy in several cases.

A fourth fish, said to give shocks like the above-mentioned, was found on the coast of Johanna, one of the Comoro islands, in lat. 12° 13′ south, by lieutenant now col. William Paterson, and an imperfect account of it is given in the 76th volume of the Philosophical Transactions.

"The fish is described to be seven inches long, two and a half broad; has a long projecting mouth, and seems of the genus tetrodon. The back of the fish is a dark-brown colour, the belly part of a sea-green, the sides yellow, and the fins and tail of a sandy-green. The body is interspersed with red, green, and white spots, the

white ones particularly bright; the eyes large, the iris red, its outer edge tinged with yellow."

Whilst this fish is living, strong shocks, like electrical shocks, are felt by a person who attempts to hold it between his hands. Three persons only are mentioned in the account as having experienced this property of one of those fishes; but the want of opportunity prevented the trial of farther experiments.

ELECTUARY, in pharmacy, a form in which both officinal and extemporaneous medicines are frequently made. See PHARMACY.

ELEGIAC, in ancient poetry, any thing belonging to elegy.

Elegiac verses are alternately hexameter and pentameter, as in the following verses of Ovid:

Flebilis indignos, elegeia, solve capillos:
Ah! nimis ex vero nunc tibi nomen erit.

Sometimes, though very rarely, the pentameter preceded the hexameter, as in the following verse of Athenæus:

Ευδαιμών Χαριτών και, Μελαιτπ@ ιφυ
Θειας αχιηρις εφεμεριοις φιλοτητ@.

Who was the inventor of elegiac poetry, is not known. Horace professes himself quite ignorant of it. The principal writers of elegiac verse, among the Latins, were Propertius, Ovid, and Tibullus, the latter of whom Quinctilian esteems the best elegiac poet, but Pliny the younger gives the preference to the first: the chief writers of elegy among the Greeks were Callimachus, Parthenius, and Euphorion.

ELEGIA, a genus of the dioecia triandria class and order. There is one species, a native of the Cape, which has the habit of a rush.

ELEGIT, in law, a writ of execution, which lies for a person who has recovered debt or damages; or upon a recognizance in any court, against a defendant that is not able to satisfy the same in his goods. It is directed to the sheriff, commanding him to make delivery of a moiety of the party's lands, and all his goods, beasts of the plough excepted; this is done by a jury, summoned to inquire what land the defendant had at the time of judgment obtained; and the creditor, by virtue thereof, shall hold the said moiety of land delivered to him, until his whole debt and damages are paid and satisfied: and during that time he is tenant by elegit. This writ ought to be sued out within a year and a day after the judgment. All other writs of execution may be good, though not returned, except an elegit; but that must be returned when executed, because an execution is taken upon it, and that the court may judge of the sufficiency of it.

ELEGY, a mournful and plaintive kind of poem. See POETRY.

ELEMENT, in physiology, a term used by philosophers to denote the original component parts of bodies, or those into which they are ultimately resolvable.

It seems to have been an opinion established among philosophers in the remotest ages, that there are only four simple bodies; namely, fire, air, water, and earth. To these they gave the name of elements, because they believed that all substances are composed of these four. This opinion, variously modified indeed, was maintained by all the ancient philosophers. We now know that all these supposed elements are compounds: fire is composed of caloric and light; air of caloric, oxygen, and azotic gases; water of oxygen and hydrogen; and the earth includes nine different substances.

The doctrine of the four elements seems to have continued undisputed till the time of the alchemists. These men having made themselves much better acquainted with the analysis of bodies than the ancient philosophers had been, soon perceived that the common doctrine was inadequate to explain all the appearances that were familiar to them. They substituted a theory of their own in its place. According to them, there are three elements, of which all bodies are composed; namely, salt, sulphur, and mercury, which they distinguish by the appellation of the tria prima. These principles were adopted by succeeding writers, particularly by Paracelsus, who added two more to their number; namely, phlegm and caput mortuum.

It is not easy to say what the alchemists meant by salt, sulphur, and mercury; probably they had fixed no precise meaning to the words. Every thing which is fixed in the fire they seem to have called salt, every inflammable substance they called sulphur, and every substance which flies off without burning was mercury. Accordingly they tell us, that all bodies may by fire be decomposed into these three principles; the salt remains behind fixed, the sulphur takes fire, and the mercury flies off in the form of smoke. The phlegm and caput mortuum of Paracelsus were the water and earth of the ancient philosophers.

Mr. Boyle attacked this hypothesis in his Sceptical Chemist, and in several of his other publications; proving that the chemists comprehended under each of the terms salt, sulphur, mercury, phlegm, and earth, substances of very different properties; that there is no proof that all bodies are composed of these principles; and that these principles themselves are not elements but compounds. The refutation of Mr. Boyle was so complete, that the hypothesis of the tria prima seems to have been almost immediately abandoned by all parties.

Meanwhile a very different hypothesis was proposed by Beecher in his Physica Subterranea; an hypothesis to which we are indebted for the present state of the science, because he first pointed out chemical analysis as the true method of ascertaining the elements of bodies. According to him, all terrestrial bodies are composed of water, air, and three earths; namely, the fusible, the inflammable or sulphureous, and the mercurial. The three earths, when they are combined in nearly equal proportions, compose the metals; when the proportion of mercurial earth is very small, they compose stones; when the fusible predominates, the resulting compounds are the precious stones; when the sulphureous predominates, and the fusible is deficient, the compounds are the calorific earths: fusible earth and water compose a universal acid, very much resembling sulphuric acid, from which all other acids derive their acidity; water, fusible earth, and mercurial earth, constitute common salt; sulphureous earth, and the universal acid, form sulphur.

Stahl modified the theory of Beecher considerably. He seems to have admitted the universal acid as an element; the mercurial earth he at last discarded altogether; and to the sulphureous earth he sometimes gave

the name of phlogiston, sometimes of ether. Earths he considered as of different kinds, but containing all a certain element called earth. So that, according to him, there are five elements; air, water, phlogiston, earth, and the universal acid. He speaks too of heat and light, but it is not clear what his opinion was respecting them.

Stahl's theory was gradually modified by succeeding chemists. The universal acid was tacitly discarded, and the different known acids were considered as distinct undecomposed or simple substances: the different earths were distinguished from each other, and all the metallic calces were considered as distinct substances. For these changes chemistry was chiefly indebted to Bergman. While the French and German chemists were occupied with theories about the universal acid, that illustrious philosopher, and his immortal friend and fellow-labourer Scheele, loudly proclaimed the necessity of considering every undecomposed body as simple till it has been decomposed, and of distinguishing all those substances from each other which possess distinct properties. These cautions, and the consequent arrangement of chemical bodies into distinct classes by Bergman, soon attracted attention, and were at last tacitly acceded to.

Thus the elements of Stahl were in fact banished from the science of chemistry, and in place of them were substituted a great number of bodies which were considered as simple, because they had not been analysed. These were phlogiston, acids, alkalies, earths, metallic calces, water, and oxygen. The rules established by Bergman and Scheele are still followed; but subsequent discoveries have shown that most of the bodies which they considered as simple are compounds; while several of their compounds are now placed among simple bodies, because the belief in the existence of phlogiston, which they considered as a component part of these bodies, is now discarded.

As the term simple substance in chemistry means nothing more than a body whose component parts are unknown, it cannot be doubted that, as the science advances towards perfection, many of those bodies which we consider at present as elementary will be decomposed, and most probably a new set of elementary bodies will come into view, of which we are at present ignorant. These may be decomposed in their turn, and new simple bodies discovered; till at last, when the science reaches the highest point of perfection, those really simple and elementary bodies will come into view of which all substances are ultimately composed. When this happens, (if it is not above the reach of the human intellect) the number of simple substances will probably be much smaller than at present. Indeed it has been the opinion of many distinguished philosophers in all ages, that there is only one kind of matter; and that the difference which we perceive between bodies depends upon varieties in the figure, size, and density of the primary atoms when grouped together. This opinion was adopted by Newton, and Boscovich has built upon it an exceedingly ingenious and instructive theory.

We must observe, however, that this opinion is mere hypothesis, wholly unsupported by fact and experiment; and indeed all experiment may be said hitherto to be directly against it. In the present state of science, the following may be regarded as simple or elementary substances, and we have little doubt that many of them will ultimately prove such.

Dr. Thomson makes out the number of simple substances at present known to be about 33, and these he divides into two classes. The bodies belonging to the first class can be confined in proper vessels, and exhibited in a separate state; these he calls confinable bodies. Those which belong to the second class are of too subtile a nature to be confined by any vessels that we possess: they cannot therefore be exhibited in a separate state, and their existence is inferred merely from certain phenomena, which the first class of bodies and their compounds exhibit in particular circumstances; these he denominates unconfinable bodies. It is evident that a person must be acquainted with the properties of the first set of bodies before he can investigate the second.

Table of simple substances.

I. Confinable bodies.

1.	Oxygen
2. Simple combustibles	Sulphur
	Phosphorus
	Carbon or Diamond
	Hydrogen
3. Simple incombustibles	Azote or Nitrogen
	Muriatic acid
4. Metals	Gold
	Platinum
	Silver
	Mercury
	Copper
	Iron
	Tin
	Lead
	Nickel
	Zinc
	Bismuth
	Antimony
	Tellurium
	Arsenic
	Cobalt
	Manganese
	Tungsten
	Molybdenum
	Uranium
	Titanium
	Chromium
	Columbium
	Tantalium
5. Alkalies	Potas { or vegetable and
6. Earths	Soda { mineral alkalies.

The vegetable and mineral alkalies, and some of the earths, are supposed to be compounds, though they have not yet been analyzed: these of course, belong to the first class, viz. confinable bodies.

- Barytes
- Strontian
- Lime
- Magnesia
- Alumina
- Yttria
- Glucina
- Zirconia
- Silica.

II. Unconfinable bodies.

Light
Caloric
Electricity
Magnetism.

ELENCHUS, in logic, a sophism, or fallacious argument, which deceives the hearer under the appearances of truth.

ELEPHAS, the ELEPHANT, a genus of the mammalia class, of the order bruta. The generic character is, cutting-teeth none in either jaw; tusks in the upper jaw; proboscis very long, prehensile; body nearly naked.

1. The elephas maximus, the great elephant. The stupendous size, strength, and segacity of the elephant, have, in all ages, rendered it the admiration of mankind. Though possessed of power superior to every other quadruped, it is guiltless of unprovoked violence, and wanders about the woods of Asia and Africa in a state of majestic mildness. Elephants are naturally gregarious. Large troops assemble together, and live in a kind of society. They feed only on vegetables. The elephant is generally of a deep ash-coloured brown, or nearly blackish; but in some parts of India it is said to be found, though very rarely, of a white colour. In the young animals the tusks are not visible: in the more advanced state of growth they are extremely conspicuous: and in the full-grown animal they advance several feet from the mouths of their sockets: it is but rarely that the tusks are seen in the females; and when they appear, they are but small, and their direction is rather downwards than upwards: this is also the case in some specimens of the male elephant, so that there appears to be some variation in this respect in different individuals. Tusks have sometimes been seen upwards of ten feet long; particularly from the Mosambique and Cochinchina.

The teeth which are imported into Europe are generally from Africa, where they are frequently found in the woods. Instances have sometimes occurred, in which, on sawing a tooth, a brass bullet has been found completely imbedded in the central part of the tooth; the ivory having gradually grown over it, and inclosed it.

The elephant is undoubtedly the largest of all terrestrial animals, arriving at the height of twelve feet, though the more general height seems to be from nine to ten feet. Elephants are commonly found in the midst of shady woods, being equally averse to extreme heat as to cold: they delight in cool spots, near rivers, and frequently bathe themselves in the water, and even roll in the mud. They are also capable of swimming with great ease. Their general food consists of the tender branches of various trees, as well as of grains and fruits. It is for this reason that their incursions are so much dreaded in plantations of various kinds, where they are said occasionally to commit the most violent depredations; at the same time, injuring the crops by trampling the ground with their vast feet. The trunk of the elephant may justly be considered as one of the miracles of nature; being at once the organ of respiration, and the instrument by which the animal supplies itself with food; conveying whatever it eats into the mouth by its assistance. By this instrument also it drinks; first sucking up the water by the trunk, and then pouring it into the mouth. This wonderful organ is composed of a vast number of flexible rings; and consists of a double tube, with a somewhat flattened circular tip, furnished with a projecting point, or fleshy moveable hook, of extreme sensibility, and with which it can pick up the smallest object at pleasure. The trunk, being flexible in all directions, performs the office of a hand and arm. On its under surface it is somewhat flattened, and is circularly formed on the upper. At the end of the trunk are situated the nostrils. The teats of the female elephant are two in number, and are situated at a small distance behind the fore-legs. The eyes are extremely small, the ears very large, somewhat irregularly waved on the edges, and pendulous. In each jaw are four [illegible] flat grinding teeth, with the upper surfaces flat, and scored or striated with numerous transverse furrows. In the upper jaw are the two tusks before described. The form of the whole animal is extremely awkward; the head very large, the body very thick, the back greatly arched; the legs extremely thick, very short; and the feet slightly divided into, or rather edged with, five rounded hoofs; the tail is of a moderate length, and is terminated by a few scattered hairs, of great thickness, and of a black colour: the skin has a few thinly scattered hairs or bristles dispersed over it, and which are somewhat more numerous about the head.

The tales related of the sagacity of the elephant are, in all probability, somewhat exaggerated, and must consequently be received with a degree of limitation: but there is no reason to doubt that they are possessed of a greater degree of intelligence than most other quadrupeds (the dog excepted); and that, when in a state of domestication, they may be taught to perform many operations, requiring not only strength, but skill in their execution. It appears, from the most authentic information, that they are highly attached to those who have them under their care: that they are grateful for attentions shown them, and mindful of any injury received; which they generally find some means of retaliating. Some elegant anecdotes of this kind are related by Pliny; and the laborious Aldrovandus has collected many others. The celebrated story of the taylor of Delhi is a remarkable example of the elephant's sagacity. In that city an elephant, passing along the streets, put his trunk into a taylor's shop, where several people were at work: one of them pricked the end of the trunk with his needle: the elephant passed on; but in the first dirty puddle, filled his trunk with the water, and returning, squirted every drop among the people who had offended him, and spoiled the rich garments they were at work upon.

It is said that elephants have been taught to lade vessels with goods, which they have stowed in proper order, and with much address.

The Indian elephants, but more especially those of the island of Ceylon, excel the African elephants in size and strength. Those of India are said to carry with ease three or four thousand weight. In a state of nature they use the tusks for tearing up trees, and the trunk for breaking the branches. It has been affirmed that they run as swift as a horse can gallop; but Mr. Pennant assures us, that what has been said

on this subject is a mistake; and that a nimble Indian can easily outstrip them.

The contrivances for taking elephants are various. The Ceylonese sometimes surround the woods in bands, and drive with lighted torches, and all manner of noises, the elephants which inhabit them, till they are at length entrapped into a particular spot surrounded with palisades, so as to prevent all escapes. At other times a kind of decoy, or female elephant, is sent out in order to induce some of the males to pursue her, who are by this means secured. When a wild elephant is taken, it still remains to reduce it to a quiet state; and to tame it, in order to be made useful: this is effected by throwing ropes round the legs and body, which are well secured; and two tame elephants, properly instructed, are placed on each side. The captive animal finds himself gradually so fatigued by his ineffectual struggles, and so much soothed by the caresses occasionally given by the trunks of the tame elephants, by the food from time to time presented to him, and the water with which he is refreshed by pouring it over him, that in the space of some days he becomes completely tame, and is placed with the rest of the domesticated troop. Sometimes, in order to subdue them the more effectually, they are deprived of sleep for a considerable time.

Great care is taken by the grandees of India in the management and decoration of their elephants; which, after their daily feeding, bathing, oiling, and rubbing, are often painted about the head and ears with various colours, and their tusks are surrounded with rings of gold or silver: and when employed in processions, &c. they are clothed in the most sumptuous trappings.

By the ancient Indians they were much used in war; and we are told that Porus, the Indian monarch, opposed the passage of Alexander over the Hydaspes with eighty-five elephants. Buffon also imagines that some of the elephants which were taken by Alexander, and sent into Greece, were employed by Pyrrhus against the Romans. The Romans received their elephants from Africa, and that in great numbers; since it appears that Pompey entertained the people with a show of eighteen in the space of five days, which were all destroyed in conflicts with armed men. Fifty lions were also exhibited in the same space. The crying and distress of the wounded elephants are said to have excited much commisseration among the Roman people. It is highly remarkable, if true, that the young elephants do not attach themselves to their dams in particular, but suck indiscriminately the females of the whole herd. Mr. Bruce, however, in his Travels, gives a particular description of the more than common attachment of a young elephant to its dam, which it endeavoured to defend, when wounded, and with much fierceness assaulted the invaders. The young elephants do not suck by the trunk, but by the mouth.

The elephant brings only one young at a time; very rarely two: the young are about three feet high when they are first born, and continue growing till they are sixteen or twenty years old; they are said to live a hundred, or a hundred and twenty years.

In the Philosophical Transactions for the year 1799, we find some curious particulars relative to the natural history of the elephant, by Mr. Corse, whose residence in India afforded him opportunities of investigating the subject with exactness.

From these observations it appears that something must be subtracted from that elevated character with which this animal has been so frequently honoured; and that neither its docility nor its memory can be allowed a very high rank, when compared with those of some other animals; and that the scrupulous delicacy, which, as it was pretended, forbade all public demonstrations of its passions, is a mere fable. A female elephant has also been known to forget her young one, after having been separated from it for the short space of only two days, and to repel its advances. An elephant, also, which had escaped from its confinement, has again suffered itself to be trepanned, and reconducted to its state of captivity.

Both male and female elephants, Mr. Corse informs us, are divided by the natives of Bengal into two casts, viz. the koomareah, and the merghee. The first consists of the large or full-bodied kind; the second of the more slender, with longer legs and thinner trunk in proportion; it is also a taller animal, but not so strong as the former. A large trunk is always considered as a great beauty in an elephant, so that the koomareah is preferred not only on this account, but for his superior strength in carrying burthens, &c. Many indistinct varieties are again produced from the intermixture of these two breeds. The torrid zone seems to be the natural clime of the elephant, and the most favourable for the production of the largest and hardiest race; and when this animal migrates beyond the tropics, the species degenerates. On the coast of Malabar elephants are taken as far north as the territories of Coorgah Rajah; but these, according to Mr. Corse, are much inferior to the Ceylonese elephant.

The tusks in some female elephants are so small as not to appear beyond the lip; whilst in others they are large and long, as in one variety of the male, called mooknah. The grinders are so much alike in both sexes, that one description may serve for both. The largest tusks, and from which the best ivory is supplied, are taken from that kind of male elephant, called dauntelah, from this circumstance, in opposition to the mooknah, whose tusks are not larger than those of some females. An elephant is said to be perfect when his ears are large and rounded, not ragged or indented at the margin: his eyes of a dark hazel-colour, free from specks: the roof of his mouth and his tongue without dark or blackish spots of any considerable size: his trunk large: his tail long, with a tuft of hair reaching nearly to the ground. There must be five nails in each of his fore-feet, and four on each of the hind ones: his head well set on, and carried rather high: the arch or curve of his back rising gradually from the shoulder to the middle, and thence descending to the insertion of the tail: and all his joints firm and strong. In one variety of the elephant the tusks point downwards, projecting only a little way beyond the trunk. The tusks in elephants are fixed very deep in the upper jaw; and the root, or upper part, which is hollow, and filled with a core, goes as high as the insertion of the trunk, round the margin of the nasal opening of the throat; which opening is just below the protuberance of the forehead. Through the opening the elephant breathes, and by its means he sucks up water

into his trunk; between it and the roots of the tusks there is only a thin bony plate. The first or milk-tusks of an elephant never grow to any considerable size, but are shed between the first and second year, when not two inches in length. The time at which the tusks cut the gum varies considerably; sometimes a young elephant has his tusks at five months old, and sometimes not till seven. Even in a fœtus which has arrived at its full time, these deciduous tusks are formed. A young elephant shed one of his milk-tusks the 6th of November, 1790; when about thirteen weeks old; and the other on the 7th of December, when above four months old. Two months afterwards the permanent ones cut the gums, and on the 19th of April, 1791, they were an inch long. Another young elephant did not shed his milk-tusks till he was sixteen months old, which proves that the time of this process varies considerably. The permanent tusks of the female are very small, compared with those of the male: and do not take their rise so deep in the jaw. The largest elephant-tusks Mr. Corse ever saw in Bengal, did not exceed the weight of seventy-two pounds avoirdupois: at Tiperah they seldom exceed fifty-two pounds each. Both these weights are very inferior to that of the tusks brought from other parts to the India-house, where some have weighed 150 pounds each. These, Mr. Corse suspects, were from Pegu. The African elephant is said to be smaller than the Asiatic: yet the ivory-dealers in London affirm that the largest tusks come from Africa, and are of a better texture, and less liable to turn yellow, than the Indian ones. The increase of the tusks arise from circular layers of ivory, applied internally, from the core on which they are formed; similar to what happens in the horns of some animals. See plate L. Nat. Hist. fig. 176.

2. The sukotyro. That we may not seem to neglect so remarkable an animal, though hitherto so very imperfectly known, we shall here introduce the sukotyro. This, according to Niewhoff, its only describer, and who has figured it in his travels to the East Indies, is a quadruped of a very singular shape. Its size is that of a large ox; the snout like that of a hog; the ears round and rough; and the tail thick and bushy. The eyes are placed upright in the head, quite differently from those of other quadrupeds. On each side the head, next to the eyes, stand the horns, or rather teeth, not quite so thick as those of an elephant. This animal feeds upon herbage, and is but seldom taken. It is a native of Java, and is called by the Chinese sukotyro. This is all the description given by Niewhoff. The figure is repeated in Churchill's Collection of Voyages and Travels, vol. ii. p. 360. Niewhoff was a Dutch traveller, who visited the East Indies about the middle of the 16th century, viz. about the year 1563, and continued his peregrinations for several years. It must be confessed, that some of the figures introduced into his works are not remarkable for their accuracy.

ELEPHANT, *knights of the*, an order of knighthood in Denmark, conferred upon none but persons of the first quality and merit. It is also called the order of St. Mary. Its institution is said to have been owing to a gentleman among the Danish croisees having killed an elephant, in an expedition against the Saracens, in 1184; in memory of which king Canutus instituted this order, the badge of which is a towered elephant, with an image of the Holy Virgin incircled with rays, and hung on a watered sky-coloured ribbon, like the George in England.

ELEPHANTIASIS, called also the lepra of the Arabians, in medicine, a chronical disease, one of the two species of leprosy, which affects the whole body, where even the bones as well as the skin are covered with spots and tumours, which being red, at last turn black. See MEDICINE.

ELEPHANTINE, in Roman antiquity, an appellation given to the books in which were registered the transactions of the senate and magistrates of Rome, of the emperors or generals of armies, and even of the provincial magistrates; the births and classes of the people, and other things relating to the census. They are supposed to have been so called as being made of ivory, though some will have them to have been written on the intestines of the elephants.

ELEPHANTOPUS, BASTARD-SCABIUS, in botany, a genus of the syngenesia polygamia segregata class of plants, the compound flower of which is tubulose, consisting of four or five hermaphrodite and ligulated corollulæ, with a narrow limb, divided into five nearly equal segments: the stamina are five very short filaments: the seeds are solitary, and contained in the cup, being of a compressed figure, and crowned with bristly hairs. There are four species, herbaceous plants of the East and West Indies.

ELEVATION, *angle of*, in gunnery, that comprehended between the horizon and the line of direction of a cannon or mortar; or it is that which the chase of a piece, or the axis of its hollow cylinder, makes with the plane of the horizon.

ELEVATION, in architecture, the same with an orthographic or upright draught of a building.

ELEVATION *of the host*, in the church of Rome, that part of the mass where the priest raises the host above his head for the people to adore.

ELEVATOR, the name of several muscles. See ANATOMY.

ELEVATORY, *elevatorium*, in surgery, an instrument for raising depressed or fractured parts of the scull, to be applied after the integuments and periosteum are removed. See SURGERY.

ELEUSINIA, in Grecian antiquity, a festival kept in honour of Ceres, every fourth by some states, but by others every fifth year. The Athenians celebrated it at Eleusis, a town of Attica, whence the name. It was celebrated with much ceremony, and persons of both sexes were initiated in it: it being deemed impious to neglect doing so. The mysteries were of two sorts, the lesser and the greater; of which the former were sacred to Proserpine, Ceres's daughter, and the latter to Ceres herself.

ELEUTHERIA, another festival celebrated at Platæa, by delegates from almost all the cities of Greece, in honour of Jupiter Eleutherius, or the assertor of liberty. It was instituted in memory of the victory obtained by the Grecians, in the territories of Platæa, over Mardonius, the Persian general left by Xerxes with a mighty army to subdue Greece.

ELIGIBILITY, in the Romish canon law, a bull

granted by the pope to certain persons, to qualify them to be chosen to an office, or dignity, whereof they were before incapable by want of age, birth, or the like.

ELISION, in grammar, the cutting off or suppressing a vowel at the end of a word for the sake of sound or measure, the next word beginning with a vowel. Elisions are pretty frequently met with in English poetry, but more frequently in Latin, French, &c. They chiefly consist in suppressions of the *a*, *e*, and *i*, though elision suppresses any of the other vowels: in the following example from Virgil there are three elisions:

Phillida amo ante alias.

ELIXIR, in medicine, a compound tincture extracted from many efficacious ingredients. Hence the difference between a tincture and an elixir seems to be this, that a tincture is drawn from one ingredient, sometimes with an addition of another to open it, and to dispose it to yield to the menstruum; whereas an elixir is a tincture extracted from several ingredients at the same time. See PHARMACY.

ELL, a measure of length, different in different countries; but the English ell is chiefly used in this country, which is equal to five quarters, or to a yard and a quarter. In Scotland the ell contains $37\frac{2}{10}$ English inches.

ELLIPSIS, in geometry, a curve line returning into itself, and produced from the section of a cone by a plane cutting both its sides, but not parallel to the base. See CONIC SECTIONS, and MENSURATION.

ELLIPSIS, in grammar, a figure in syntax in which one or more words are not expressed; and from this deficiency it has got the name ellipsis. To this figure, besides the ellipsis properly so called, belong apposition, synecdoche, asyndeton, zeugma, syllepsis, and prolepsis. The ellipsis is when the deficient word or words must be supplied from elsewhere; as Hectoris Andromache, where uxor is understood; that is, Andromache Hector's wife.

ELLIPSIS, in rhetoric, a figure nearly allied to preterition, when the orator, through transport of passion, passes over many things, which, had he been cool, ought to have been mentioned.

ELLIPTIC, or ELLIPTICAL, something belonging to an ellipsis. Thus we meet with elliptical compasses, elliptic conoid, elliptic space, elliptic stairs, &c. The elliptic space is the area contained within the curve of the ellipsis, which is to that of a circle described on the transverse axis, as the conjugate diameter is to the transverse axis; or it is a mean proportional between two circles, described on the conjugate and transverse axes.

ELLIPTOIDES, in geometry, a name used by some to denote infinite ellipses, defined by the equation $ay^{m+n} = bx^m (a - x)^n$. Of these there are several sorts: thus, if $ay^3 = bx^2 (a - x)$ it is a cubical elliptoid: and if $ay^4 = bx^2 (a - x)^2$, it denotes a biquadratic elliptoid, which is an ellipsis of the third order in respect of the Apollonian ellipsis.

ELLISIA, a genus of the monogynia order, in the pentandria class of plants; and in the natural method ranking under the 28th order, luridæ. The corolla is monopetalous and funnel-shaped; the berry carnous and bilocular; there are two seeds muricated or set with small raised points, the one higher than the other. There is one species, an annual plant of Virginia.

ELOGY, or EULOGY, *elogium*, a praise or panegyric bestowed on any person or thing, in consideration of its merit. The beauty of elogy consists in an expressive brevity. Elogiums should not have so much as one epithet properly so called, nor two words synonymous. They should strictly adhere to truth: for extravagant and improbable elogies rather lessen the character of the person or thing they would extol. See RHETORIC.

ELOINED, in law, signifies restrained or hindered from doing something; thus it is said, that if those within age are eloined, so that they cannot sue personally, their next friend shall sue for them.

ELONGATION, in astronomy, the digression or recess of a planet from the sun, with respect to an eye placed on our earth. The term is chiefly used in speaking of Venus and Mercury, the arch of a great circle intercepted between either of these planets and the sun, being called the elongation of that planet from the sun. But here it is to be observed, that it is only a circle which has the sun for its centre; that the greatest elongation is in a line touching the planet's orbit. For in an elliptic orbit it may be, that the elongation from the sun may grow still greater, even after it has left the place where the line joining the earth and planet touches its orbit. For after that, the true distance of the planet from the sun may increase, whilst the distance of the sun and planet from the earth does not increase, but rather decrease. But because the orbits of the planets are nearly circular, such small differences may be neglected in astronomy. The greatest elongation of Venus is found by observation to be about forty-eight degrees, and the greatest elongation of Mercury about twenty-eight degrees, upon which account this planet is rarely seen with the naked eye. See ASTRONOMY.

ELONGATION is also used for the difference in motion between the swiftest and the slowest of two planets, or the quantity of space the one has passed beyond the other.

ELONGATION, *angle of*, is an angle contained under lines drawn from the centres of the sun and planet to the centre of the earth.

ELONGATION, in surgery, is an imperfect luxation, occasioned by the stretching or lengthening of the ligaments of any joint. See SURGERY.

ELOPEMENT, is when a married woman of her own accord departs from her husband, and dwells with an adulterer; for which without voluntary reconciliation to the husband she shall lose her dower by the statute of Westminster ii. c. 34. If a wife willingly leaves her husband, and goes away and continues with avouterer, she shall be barred for ever of action to demand her dower that she ought to have of her husband's lands, if she is convicted thereof; except that her husband willingly and without coercion of the church, reconciles her, and suffers her to dwell with him; in which case, she shall be restored to her action. 13 Ed. I. st. i. c. 34. See ADULTERY.

ELOPS, a genus of fishes of the order of abdominales, of which there is but a single species, viz. the saurus, or scar-fish, which inhabits the coast of Carolina. The generic character is, tail armed above and beneath;

body long, and differing from the salmon in wanting the fleshy back-fin. Head large, smooth, shining, compressed, and flattened; eyes half-covered with the skin of the head; body slender, covered with large angular scales; tail deeply cleft, with a bony scale or spine above and beneath before it.

ELYMUS, a genus of the digynia order, in the triandria class of plants; and in the natural method ranking under the fourth order, *gramina*. The calyx is lateral, bivalved, aggregate, and multiflorous. There are eleven species, known in general by the name of lyme grass; one or other of which may be found in most parts of the world.

ELYSIUM, or ELYSIAN FIELDS, in heathen mythology, certain plains abounding with woods, fountains, verdure, and every delightful object; supposed to be the habitation of heroes and good men after death. According to some, the fable of Elysium is of Phœnician extraction, or rather founded upon the account of Paradise delivered in the scriptures.

EMANCIPATION, in the Roman law, the setting free a son from the subjection of his father; so that whatever moveables he acquires, belong in propriety to him, and not to his father, as before emancipation. Emancipation puts the son in capacity of managing his own affairs, and of marrying without his father's consent, though a minor. Emancipation differs from manumission, as the latter was the act of a master in favour of a slave, whereas the former was that of a father in favour of his son. There were two kinds of emancipation: the one tacit, which was by the son's being promoted to some dignity, by his coming of age, or by his marrying, in all which cases he became his own master of course; the other express, where the father declared before a judge, that he emancipated his son. In performing this, the father was first to sell his son imaginarily to another, whom they called pater fiduciarius, father in trust, of whom being bought back again by the natural father, he manumitted him before the judge, by a verbal declaration.

EMBALMING, is the opening of a dead body, taking out the intestines, and filling the place with odoriferous and desiccative drugs and spices, to prevent its putrifying. The Egyptians excelled all other nations in the art of preserving bodies from corruption; for some that they have embalmed upwards of 2000 years ago, remain whole to this day, and are often brought into other countries as great curiosities. Their manner of embalming was thus: They scooped the brains with an iron scoop out at the nostrils, and threw in medicaments to fill up the vacuum: they also took out the entrails, and having filled the body with myrrh, cassia, and other spices, except frankincense, proper to dry up the humours, they pickled it in nitre, where it lay soaking for 70 days. The body was then wrapped up in bandages of fine linen and gums, to make it stick like glue, and so was delivered to the kindred of the deceased, entire in all its features, the very hairs of the eye-lids being preserved. They used to keep the bodies of their ancestors, thus embalmed, in small houses, magnificently adorned, and took great pleasure in beholding them, without any change in their size, features, or complexion. The Egyptians also embalmed birds, &c. The prices for embalming were different: the highest was a talent, the next 20 minæ, and so decreasing to a very small matter; but those who had not wherewithal to answer this expense, contented themselves with infusing, by means of a syringe, through the fundament, a certain liquor extracted from the cedar, and leaving it there, wrapped up the body in salt of nitre; the oil thus preyed upon the intestines, so that when they took it out, the intestines came away with it, dried, and not in the least putrified; the body being inclosed in nitre, grew dry, and nothing remained besides the skin glued upon the bones.

The method of embalming used by the modern Egyptians, according to Maillet, is to wash the body several times with rose water, which, he elsewhere observes, is more fragrant in that country than with us; they afterwards perfume it with incense, aloes, and a quantity of other odours, of which they are by no means sparing; and then they bury the body in a winding-sheet, made partly of silk and partly of cotton, and soaked, as is supposed, with some sweet-scented water or liquid perfume, though Maillet uses only the term moistened: this they cover with another cloth of unmixed cotton, to which they add one of the richest suits of clothes of the deceased. The expense, he says, on these occasions, is very great, though nothing like what the genuine embalming cost in former times.

The principle of embalming depends either on the absorption of the fluids of the body, or the impregnation of them with some substance which will preserve the solids from putrefaction. Hence, absorbing-powders have been used, and also nitre, which powerfully acts on the flesh, though, like all other saline matter, it tends to prevent the body from drying. Dr. Hunter recommended the injecting of oil of turpentine impregnated with camphor and other aromatic gums into the blood-vessels, which is a very rational method.

EMBARGO, in commerce, an arrest on ships, or merchandise, by public authority; or a prohibition of the state, commonly on foreign ships, in time of war, to prevent their going out of port, sometimes to prevent their coming in, and sometimes both, for a limited time. The king may lay embargoes on ships, or employ those of his subjects, in time of danger, for service and defence of the nation; but they must not be for the private advantage of a particular trader or company, and therefore a warrant to stay a single ship is no legal embargo. No inference can be made from embargoes which are only in war-time, and are a prohibition by advice of council, and not at prosecution of parties. If goods are laden on board, and after an embargo, or restraint from the prince or state, comes forth, and then the master of the ship breaks ground, or endeavours to sail, if any damage accrues, he must be responsible for the same; the reason is, because his freight is due, and must be paid, nay though the goods be seized as contraband. Embargo differs from quarantine, as this last is always for the term of forty days, in which persons from foreign parts infected with the plague, are not permitted to come on shore.

EMBASSADOR, or AMBASSADOR, a public minister sent from one sovereign prince, as a representative of his person, to another. Embassadors are either ordinary or extraordinary. Embassador in ordinary, is he who constantly resides in the court of another prince, to

maintain a good understanding, and attend to the interest of his master. Till about 200 years ago, embassadors in ordinary were not heard of: all, till then, were embassadors extraordinary, that is, such as are sent on some particular occasion, and who retire as soon as the affair is despatched. By the law of nations, none under the quality of a sovereign prince can send or receive an embassador. At Athens, embassadors mounted the pulpit of the public orators, and there opened their commission, acquainting the people with their errand. At Rome they were introduced to the senate, and delivered their commissions to them.

Embassadors should never attend any public solemnities, as marriages, funerals, &c. unless their masters have some interest in it; nor must they go into mourning on any occasions of their own, because they represent the person of their prince. By the civil law, the moveable goods of an embassador, which are accounted an accession to his person, cannot be seized on, neither as a pledge, nor for payment of a debt, nor by order or execution of judgment, nor by the king's or state's leave where he resides, as some conceive; for all actions ought to be far from an embassador, as well that which touch his necessaries as his person; if, therefore, he has contracted any debt, he is to be called upon kindly, and if he refuses, then letters of request are to go to his master. Nor can any of the embassador's domestic servants, that are registered in the secretaries of state's office, be arrested in person or goods; if they are, the process shall be void, and the parties suing out and executing it, shall suffer and be liable to such penalties and corporal punishment as the lord chancellor, or either of the chief justices, shall think fit to inflict. Yet embassadors cannot be defended when they commit any crime against that state, or the person of the prince, with whom they reside; and if they are guilty of treason, felony, &c. or any other crime against the law of nations, they lose the privilege of an embassador, and may be subject to punishment as private aliens.

EMBER-WEEKS, are those wherein the ember or embring days fall. In the laws of king Alfred, and those of Canute, those days are called ymbren, that is, circular days, whence the word was probably corrupted into ember-days; by the canonists they are called quatuor anni tempora, the four cardinal seasons, on which the circle of the year turns: and hence Henshaw takes the word to have been formed, viz. by corruption from temper or tempora. The ember days are, the Wednesday, Friday, and Saturday, after Quadragesima Sunday, after Whitsunday, after Holy-rood day in September, and after St. Lucia's day in December; which four times answer well enough to the four quarters of the year, spring, summer, autumn, and winter. Mr. Somner thinks they were originally fasts, instituted to beg God's blessing on the fruits of the earth. Agreeably to which, Skinner supposes the word ember taken from the ashes, embers, then strewed on the head. These ember-weeks are now chiefly taken notice of, on account of the ordination of priests and deacons; because the canon appoints the Sundays next succeeding the ember-weeks, for the solemn times of ordination; though the bishops, if they please, may ordain on any Sunday or holiday.

EMBERIZA, in ornithology, a genus of birds belonging to the order of passeres. The bill is conical, and the mandibles recede from each other towards the base; the interior mandible has the sides narrowed inwards, but the upper one is still narrower. There are 24 species, of which the most remarkable are,

1. The nivalis, or great pyed mountain-finch of Ray, and the snow-bird of Edwards, it has white wings, but the outer edges of the prime feathers are black; the tail is black, with three white feathers on each side. These birds are called in Scotland snow-flakes, from their appearance in hard weather and in deep snows. They arrive in that season among the Cheviot-hills and in the Highlands in amazing flocks. A few breed in the Highlands, on the summit of the highest hills, in the same places with the ptarmigans; but the greatest numbers migrate from the extreme north. They appear in the Shetland islands, then in the Orkneys; and multitudes of them often fall, wearied with their flight, on vessels in the Pentland-frith. Their appearance is a certain forerunner of hard weather, and storms of snow, being driven by the cold from their common retreats. Their progress southward is probably thus; Spitzbergen and Greenland, Hudson's-bay, the Lapland Alps, Scandinavia, Iceland, the Ferroe Isles, Shetland, Orkneys, Scotland, and the Cheviot-hills. They visit at that season all parts of the northern hemisphere, Prussia, Austria, and Siberia. They arrive lean, and return fat. In Austria they are caught and fed with millet, and, like the ortolan, grow excessively fat. In their flights they keep very close to each other, mingle most confusedly together, and fling themselves collectively into the form of a ball; at which instant the fowler makes great havock among them. See Plate L. Nat. Hist. fig. 179.

2. The miliaris, or grey emberiza, is of a greyish colour, spotted with black in the belly, and the orbits are reddish. It is the bunting of English authors, and a bird of Europe.

3. The hortulana, or ortolan, has black wings; the first three feathers on the tail are white on the edges, only the two lateral are black outwardly. The orbits of the eyes are naked and yellow; the head is greenish, and yellow towards the inferior mandible. It feeds principally upon the millet, grows very fat, and is reckoned a delicate morsel by certain epicures, especially when fattened artificially. These birds are found in several parts of Europe, but are not met with in Britain; are common in France and Italy, and some parts of Germany and Sweden, migrating from one to the other in spring and autumn; and in their passage are caught in numbers, in order to fatten for the table. This species will sometimes sing very prettily, and has been kept for that purpose. The song is not unlike that of the yellow-hammer, but finer and sweeter. In some parts it makes the nest in a low hedge, in others on the ground. It is carelessly constructed, not unlike that of the lark. The female lays four or five greyish eggs, and in general has two broods in a year. These birds receive both their Greek and Latin name from their food, the millet. Aristotle calls them cynchromi, and the Latins miliariæ. The latter kept and fattened them in their ornithones, or fowl-yards, as the Italians do at present.

4. The citrinella, or yellow-hammer, has a blackish tail, only the two outward side-feathers are marked on

the inner edge with sharp white spots. It is a bird of Europe, and comes about houses in winter; it builds its nest in banks or on low fences.

5. The schœniclas, or reed-sparrow, has a black head, a blackish-grey body, and a white spot on the quill-feathers. It inhabits marshy places, most commonly among reeds, from which it takes its name. Its nest is worthy of notice for the artful contrivance of it, being fastened to four reeds, and suspended by them like a hammock, about three feet above the water; the cavity of the nest is deep, but narrow; and the materials are bushes, fine bents, and hairs. It lays four or five eggs of a blueish white, marked with irregular purplish veins, especially on the larger end. It is a bird much admired for its song, and like the nightingale sings in the night.

6. The oryzivora, or rice-bunting, with the head and whole under-side of the body black; hind part of the neck in some pale yellow, and in others white; coverts of the wings and primaries, black, the last edged with white; part of the scapulars, lesser coverts of the wings, and rump, white; back black, edged with dull yellow; tail of the same colours, and each feather sharply pointed; the legs are red.

7. The cirlus is brown; breast spotted; eye-brows pale yellow; the two outmost tail-feathers with a white wedged spot. It inhabits France and Italy, and feeds on seeds, worms, and insects. See Plate L. Nat. Hist. fig. 177.

8. The ciris; the head blue; belly orange; back green; the feathers green-brown. Inhabits South America; varies in colour by age, sex, or climate; builds in orange groves. See fig. 178.

These birds inhabit, in vast numbers, the island of Cuba, where they commit great ravages among the early crops of rice, which precede those of Carolina. They arrive very lean; but soon grow so fat, as to fly with difficulty, and when shot, often burst with the fall. They continue in Carolina not much above three weeks, and retire by the time the rice begins to harden; going on to other parts, and staying in each only so long as the rice continues green. They come into Rhode-island and New York at the end of April, or the second week in May, frequenting the borders of fields, and live on insects, &c. till the maize is fit for their palates, when they begin by pecking holes in the sides of the husk, and after satiating themselves go on to another, which leaves room for the rain to get in, and effectually spoils the plants. They continue there during the summer, and breed, returning as autumn approaches to the southward. The males and females do not arrive together; the females come first. They are esteemed to be the most delicate birds of those parts; and the male is said to have a fine note.

EMBEZZLEMENT. By stat. 39 G. III. c. 85, for protecting masters against embezzlements by their clerks, and servants; servents or clerks, or persons employed for the purpose or in the capacity of servants or clerks, who shall, by virtue of such employment, receive or take into their possession any money, goods, bond, bill, note, banker's draft, or other valuable security or effects, for, or in the name, or on the account of, their master or employer; and who shall fraudulently embezzle, secrete, or make away with the same, or any part thereof; every such offender shall be deemed to have feloniously stolen the same from his master or employer, for whose use, or on whose account, the same was delivered to, or taken into the possession of such servant, clerk, or other person so employed, although such money, goods, bond, bill, note, banker's draft, or other valuable security, was or were no otherwise received into the possession of his or their servant, clerk, or other person so employed; and every such offender, his adviser, procurer, aider, or abettor, being thereof lawfully convicted or attainted, shall be liable to be transported to such part beyond the seas as his majesty, by and with the advice of his privy council, shall appoint, for any term not exceeding fourteen years, in the discretion of the court before whom such offender shall be convicted or adjudged.

EMBLEM, a kind of painted enigma, or certain figures painted or cut metaphorically, expressing some action with reflections underneath, which in a measure explain the sense of the device, and at the same time instruct us in some moral truth, or other matter of knowledge. The emblem is somewhat plainer than the enigma, and the invention is more modern, it being entirely unknown to the ancients.

EMBLEMENTS, signify the profits of land sown; but the word is sometimes used more largely, for any profits that arise and grow naturally from the ground, as grass, fruit, hemp, flax, &c. Cowel.

EMBRACERY, is an attempt to corrupt or influence a jury, or any way incline them to be more favourable to the one side than the other, by money, promises, letters, threats, or persuasions; whether the juror on whom such attempt is made, gives verdict or not, or whether the verdict given be true or false. 1 Haw. 259. The punishment of an embracer, or embracetor, is by fine and imprisonment; and for the juror so embraced, if it is by taking money, the punishment is (by divers statutes) perpetual infamy, imprisonment for a year, and forfeiture of tenfold the value. 4 Black. 140.

EMBOLISMIC, or Intercalary, a termed used by chronologists in speaking of the additional months and years, which they insert to bring the lunar to the solar year. Since the common lunar year consists of 12 synodic months, or 354 days nearly, and the solar consists of 365 days (omitting the odd hours and minutes), it is plain that the solar year will exceed the lunar by about 11 days; and consequently in the space of about 33 years the beginning of the lunar year will be carried through all the seasons, and hence it is called the moveable lunar year. This form of the year is used at this time by the Turks and Arabians; and because in three years time, the solar year exceeds the lunar by 33 days, therefore, to keep the lunar months in the same seasons and times of the solar year, or near it, chronologists added a whole month to the lunar year every third year, and so made it consist of 13 months; this year they called the embolismic year, and the additional month the embolismic, or embolimean, or intercalary month. This form of the year is called the fixed lunar year, and it was used by the Greeks and Romans till the time of Julius Cæsar.

EMBOSSING, or Imbossing, in architecture and

sculpture, the forming or fashioning works in relievo, whether cut with a chissel or otherwise. Embossing is a kind of sculpture, in which the figures stick out from the plane; and according as the figures are more or less prominent, they are said to be in alto, mezzo, or basso relievo; or high, mean, or low relief.

EMBOTHRUM, a genus of the class and order tetrandria monogynia. The corolla is four-petalled; anthers sessile, sitting on the tips of the petals; follicle round. There are four species, handsome shrubs of New Holland and South America.

EMBRASURE. See ARCHITECTURE.

EMBRASURE, in fortification, a hole or aperture in a parapet, through which the cannon are pointed to fire into the moat or field. See FORTIFICATION.

EMBROCATION, in surgery and pharmacy, an external kind of remedy, which consists in an irrigation of the part affected, with some proper liquor, as oils, spirits, &c. by means of a woollen or linen cloth, or a sponge, dipped in the same. See SURGERY.

EMBROIDERY, a work in gold or silver, or silk thread, wrought by the needle upon cloth, stuffs, or muslin, into various figures. In embroidering stuffs, the work is performed in a kind of loom, because the more the piece is stretched, the easier it is worked. As to muslin, they spread it upon a pattern ready designed; and sometimes, before it is stretched upon the pattern, it is starched, to make it more easy to handle. Embroidery on the loom is less tedious than the other, in which, while they work flowers, all the threads of the muslin, both lengthwise and breadthwise, must be continually counted; but on the other hand this last is much richer in points, and susceptible of greater variety. Cloths too much milled are scarcely susceptible of this ornament, and in effect we seldom see them embroidered. The thinnest muslins are the best for this purpose, and they are embroidered to the greatest perfection in Saxony. In other parts of Europe, however, they embroider very prettily, and especially in France.

There are several kinds of embroidery, as, 1. Embroidery on the stamp, where the figures are raised and rounded, having cotton or parchment put under them to support them. 2. Low embroidery, where the gold and silver lie low upon the sketch, and are stitched with silk of the same colour. 3. Guimped embroidery: this is performed either in gold or silver; they first make a sketch upon the cloth, then put on cut vellum, and afterwards sow on the gold and silver with silk-thread. In this kind of embroidery they often put gold and silver cord, tinsel, and spangles. 4. Embroidery on both sides; that which appears on both sides of the stuff. 5. Plain embroidery; where the figures are flat and even, without cords, spangles, or other ornaments.

No foreign embroidery, or gold or silver brocade, is permitted to be imported into England on pain of being seized and burned, and a penalty of 100*l.* for each piece. No person is allowed to sell any foreign embroidery, gold or silver thread, lace, fringe, or brocade, or make up the same into any garment, upon pain of having it burned, and penalty of 100*l.*

EMBRYULCUS. See MIDWIFERY.

EMERALD, in natural history, a precious stone, of a green colour, and next in hardness to the ruby.

This stone has hitherto been found almost always crystallized. The primitive form of the crystals is a regular six-sided prism; and the form of its particles is a triangular prism, whose sides are square, and bases equilateral triangles. The most common variety of its crystals is the regular six-sided prism, sometimes with the edges of the prism, or of the bases, or the solid angles, or both wanting, and small faces in their place. The sides of the prism are generally channelled.

Its texture is foliated. Its fracture conchoidal. Causes a double refraction. Hardness 12. Specific gravity 2.65 to 2.775. Colour green. Becomes electric by friction, but not by heat. Its powder does not phosphoresce when thrown on a hot iron. At 150° Wedgewood it melts into an opaque coloured mass. According to Dolomieu, it is fusible per se by the blowpipe.

This mineral was formerly subdivided into two distinct species; the emerald, and beryl or aqua marina. Hauy demonstrated, that the emerald and beryl correspond exactly in their structure and properties; and Vauquelin found that they were composed of the same ingredients: henceforth, therefore, they must be considered as varieties of the same species.

The variety called emerald varies in colour from the pale to the perfect green. It comes chiefly from Peru; some specimens have been brought from Egypt. Dolomieu found it in the granite of Elba. When heated to 120° Wedgewood, it becomes blue, but recovers its colour when cold. A specimen, analysed by Vauquelin, was composed of

64.60	silica
14.00	alumina
15.00	glucina
3.50	oxide of chromium
2.56	lime
2.00	moisture, or other volatile ingredient
99.66	

See BERYL.

The beryl is of a mountain-green colour, and sometimes blue, yellow, and even white; sometimes different colours appear in the same stone. It is found in Ceylon, different parts of India, Brazil, and especially in Siberia and Tartary, where its crystals are sometimes a foot long. A specimen of beryl, analysed by Vauquelin, contained

69	silica
13	alumina
1	oxide of iron
0.5	lime
83.5	

It was by analysing this stone that Vauquelin discovered the earth which he called glucina.

Our jewellers distinguish emeralds into two kinds, the oriental and occidental: the emeralds of the East Indies are evidently finer than those of any other part of the world; but our jewellers, seldom meeting with these, call the American emeralds the oriental, and usually sell crystals accidentally tinged with green, under the name of occidental emeralds: these being also the most common, there has grown an opinion among the lapidaries, that the emerald is no harder than the crystal; because what they take to be the emeralds, are in general only crystals. The genuine emerald, in its most

perfect state, is perhaps the most beautiful of all the gems; it is found of various sizes, but usually small; a great number of them are met with of about the sixteenth part of an inch in diameter, and they are found from this size to that of a walnut.

EMERSION, in astronomy, is when any planet that is eclipsed begins to emerge or get out of the shadow of the eclipsing body. It is also used when a star, before hidden by the sun as being too near him, begins to reappear or emerge out of his rays. See ASTRONOMY.

EMERY, in natural history, a rich iron-ore found in large masses, of no determinate shape or size, extremely hard and very heavy. It is usually of a dusky brownish-red on the surface, but when broken, is of a fine, bright, iron-grey, but not without some tinge of redness, and is spangled all over with shining specks, which are small flakes of a foliaceous talc, highly impregnated with iron. It is also sometimes very red, and then usually contains veins of gold. It is imported from the island of Naxos, where it exists in great abundance. It is opaque and brittle; its specific gravity is about four. From the analysis of Mr. Tennant, it appears that emery, when freed as much as possible from iron, is composed of

80 alumina
3 silica
4 iron

87.

This analysis corresponds very nearly with that of the imperfect corundum.

Emery is prepared for the manufacturers by grinding in mills, and the powder is separated into parcels of different degrees of fineness by washing; these are called the first, second, and third sort; the first being that which remains longest suspended in water, the others, such as sink sooner from the same liquor, and from which it is poured, while yet turbid, to settle for the finer kind. These several sorts are of great use to various artificers in polishing and burnishing iron and steel works, marble, cutting and scalloping glass, &c. The lapidaries cut the ordinary gems on their wheels, by sprinkling the wetted powder over them. the wheels they use being usually of lead, with a small admixture of pewter, that their softness may admit the emery the better. It will not cut diamonds.

EMETIC, a medicine which induces vomiting. See PHARMACY.

EMINENCE, in the military art, a high or rising ground, which overlooks and commands the low places about it; such places within cannon-shot of a fort are a great disadvantage; for if the besiegers become masters of them, they can thence fire into the fort.

EMIR, a title of dignity among the Turks, signifying a prince, which was first given to the caliphs, but when they assumed the title of sultans, that of emir remained to their children, as that of Cæsar among the Romans. At length the title became attributed to all who were judged to descend from Mahomet by his daughter Fatimah, and who wear the green turban instead of the white. The Turks also call the viziers, bashaws, or governors of provinces, by this name.

EMOLIENTS, in medicine and pharmacy, are such remedies as sheath and soften the asperity of the humours, and relax and supple the solids at the same time. See MATERIA MEDICA.

EMPEROR, *imperator*, a title of honour among the ancient Romans, conferred on a general who had been victorious, and now used to signify a sovereign prince, or supreme ruler of an empire.

The title of emperor adds nothing to the rights of sovereignty; it only gives preeminence above other sovereigns. The emperors, therefore, pretend, that the imperial dignity is more eminent than the regal. It is disputed whether emperors have the power of disposing of the regal title; however this may be, they have sometimes taken upon them to erect kingdoms: thus it is that Bohemia, Prussia, and Poland, are said to have been raised to that dignity. In the East the title of emperor is more frequent than with us; thus the sovereign princes of China, the Mogul empire, &c. are called emperors. In the West, the title has been for a long time restrained to the emperors of Germany. The first who bore it was Charlemagne, who was crowned by pope Leo III. in 800; and it is to be observed, that there was not a foot of land or territory annexed to the emperor's title. In the year 1723, the czar of Muscovy assumed the title of emperor of all the Russias. The kings of France were also called emperors when they reigned with their sons, whom they associated in the crown: thus Hugh Capet was called emperor, and his son Robert, king. The kings of England were anciently stiled emperors, as appears from a charter of king Edgar. The emperor of Germany is a limited monarch in regard to the empire, though he is an absolute sovereign in most of his hereditary dominions.

EMPETRUM, *berry-baring heath*, a genus of the triandria order, in the monœcia class of plants. In the natural method this genus is ranked by Linnæus under the 54th order, miscellaneæ; and likewise among those of which the order is doubtful. The male calyx is tripartite; the corolla tripetalous; the stamina long: the female calyx is tripartite; the corolla tripetalous; the styles nine; the berry nine-seeded. There are two species; one of which, viz. the nigrum, bears the crow-crake berries, and is a native of Britain. It grows wild on boggy heaths and mountains. Children sometimes eat the berries; but when taken in too great a quantity, they are apt to occasion a head-ache. Grouse feed upon them. When boiled with alum, they afford a dark purple dye. Goats are not fond of the plant; cows, sheep, and horses, refuse it. The album is a native of Portugal, and bears white berries.

EMPHYSEMA, in surgery, a windy tumour, generally occasioned in a fracture of the ribs, and formed by the air insinuating itself, by a small wound, between the skin and muscles, into the substance of the cellular or adipose membrane, spreading itself afterwards up to the neck, head, belly, and other parts, much after the manner in which butchers blow up their veal. See SURGERY.

EMPHYTEUSIS, in the civil and canon law, the letting out of poor barren lands for ever, or at least for a long term of years, on condition of the tenant's cultivating, ameliorating, or mending them, and paying a certain yearly consideration. Emphyteuses are a kind of alienation, differing from sale, in that they only trans-

fer the dominion utile, the benefits of the ground, not the property, or simple fee. Among the Romans they were at first temporary, afterwards perpetual.

EMPIRE, in political geography, a large extent of land, under the jurisdiction or government of an emperor. See EMPEROR.

The most ancient empire we read of is that of the Assyrian, which was subverted through the effeminacy of Sardanapalus; the Persian empire was destroyed through the bad conduct of Darius Codomannus; the Grecian empire, by its being dismembered among the captains of Alexander the Great; and the Roman empire, through the ill management of the last emperors of Rome. Empire, or the empire, used absolutely, and without any addition, signifies the empire of Germany, called also in juridical acts and laws, the holy Roman empire. Authors are at a loss under what form of government to range this empire. Some consider it as a monarchical state, as all the members are forced to ask the investitute of their states of the emperor, and to take an oath of fidelity to him. Others will have it an aristocratic state, because the emperor cannot determine any thing without the concurrence of the princes: and, lastly, others regard the empire as a monarcho-aristocratic state.

EMPIS, in zoology, a genus of insects belonging to the order diptera, of which the characters are these: the proboscis is of an horny substance, bivalve, reflected under the head and breast, and longer than the thorax. There are five species. These minute insects live by sucking out the blood and fluids of other animals.

EMPLEURUM, a genus of the monœcia tetrandria class and order. The male calyx is four-cleft; corolla none; fem. calyx, four-cleft inferior; corolla none; stigma cylindric; caps. opening at the side; seed one, arilled. There is one species, a shrub of the Cape.

EMPYEMA, in medicine, a disorder in which purulent matter is contained in the thorax or breast, after an inflammation and suppuration of the lungs and pleura, which, if it is not timely discharged, not only obstructs respiration, but also returning into the blood occasions a continual hectic, with a consumption of the whole body, and other bad symptoms. See MEDICINE.

EMPYREUMA, among chemists and physicians, the fiery taste or offensive smell which brandies, and some other bodies prepared by fire, are impregnated with.

EMULGENT, or RENAL ARTERIES, those which supply the kidneys with blood; being sometimes single, sometimes double on each side.

EMULSION, in pharmacy, a soft liquid substance, of a colour and consistence resembling milk. See PHARMACY.

EMUNCTORY, in anatomy, a general term for all those parts which serve to carry off the excrementitious parts of the blood and other humours of the body. Such more especially are the kidneys, bladder, &c.

ENALLAGE, in grammar, is when one word is substituted for another of the same part of speech; a substantive for an adjective, as exercitus victor for victoriosus, scelus for scelestus; a primitive for a derivative, as Dardana arma for Dardania, laticem lyæum for lyæcium; an active for a passive, as nox humida cœlo præcipitat, for præcipitatur, &c.

ENALLAGE, in rhetoric, is a figure by which the discourse is changed and reversed contrary to all the rules of the language; but this is not done altogether at pleasure, or without reason.

ENALURON, according to Guillim, is a bordure charged with birds; though others will have it to signify, in orle, or form of a bordure.

ENAMEL, a kind of coloured glass, used in enamelling and painting in enamel. Enamels have for their basis a pure crystal-glass or frit, ground up with a fine calx of lead and tin prepared for the purpose, with the addition usually of white salt of tartar. These ingredients baked together are the matter of all enamels, which are made by adding colours of different kinds in powder to this matter, and melting or incorporating them together in a furnace.

For white enamel, Neri De Arte Vitriar. directs only manganese to be added to the matter which constitutes the basis; for azure, zaffer mixed with calx of brass; for green, calx of brass with scales of iron, or with crocus martis; for black, zaffer with manganese, or with crocus martis; or manganese with tartar; for red, manganese or calx of copper and red tartar; for purple, manganese with calx of brass; for yellow, tartar and manganese; and for violet-coloured enamel, manganese with thrice-calcined brass.

In making these enamels, the following general cautions are necessary to be observed. 1. That the pots must be glazed with white glass, and must be such as will bear the fire. 2. That the matter of enamels must be very nicely mixed with the colours. 3. When the enamel is good, and the colour well incorporated, it must be taken from the fire with a pair of tongs. 4. The general way of making the coloured enamels is this; powder, sift, and grind all the colours very nicely, and first mix them with one another, and then with the common matter of enamels; then set them in pots in a furnace, and when they are well mixed and incorporated, cast them into water, and when dry, set them in a furnace again to melt, and when melted take a proof of it. If too deep-coloured, add more of the common matter of enamels, and if too pale, add more of the colours.

Enamels are used either in counterfeiting or imitating precious stones, in painting in enamel, or by enamellers, jewellers, and goldsmiths, in gold, silver, and other metals. The first two kinds are usually prepared by the workmen themselves, who are employed in these arts. That used by jewellers, &c. is brought to us chiefly from Venice or Holland, in little cakes of different sizes, commonly about four inches diameter, having the mark of the maker struck upon them with a puncheon.

ENAMELLING, the art of laying enamel upon metals, as gold, silver, copper, &c. and of melting it at the fire, or of making divers curious works in it at a lamp. It signifies also to paint in enamel.

The method of painting in enamel.—This is performed on plates of gold or silver, or most commonly of copper, enamelled with the white enamel, which they paint with colours melted in the fire, where they take a brightness and lustre like that of glass. This painting is the most prized of all for its peculiar brightness and vivacity, which is very permanent, the force of its colours not being effaced or sullied with time, as in other painting, and

continuing always as fresh as when it came out of the workman's hands. It is usual in miniature, it being the more difficult the larger it is, by reason of certain accidents it is liable to in the operation. Fine enamelling should only be practised on plates of gold, the other metals being less pure: copper, for instance, scales with the application, and yields fumes; and silver turns the yellows white. Nor must the plate be made flat; for in such case, the enamel cracks; to avoid which, they usually forge them a little round or oval, and not too thick. The plate being well and evenly forged, they usually begin the operation by laying on a couch of white enamel, on both sides; which prevents the metal from swelling and blistering; and this first lay serves for the ground of all the other colours. The plate being thus prepared, they begin at first by drawing out exactly the subject to be painted with red vitriol, mixed with oil of spike, marking all parts of the design very lightly with a small pencil. After this, the colours (which are to be previously ground with water in a mortar of agate extremely fine and mixed with oil of spike somewhat thick) are to be laid on, observing the mixtures and colours that agree to the different parts of the subject; for which it is necessary to understand painting in miniature. But here the workman must be very cautious of the good or bad qualities of the oil he employs to mix his colours with, for it is very subject to adulterations. Great care must likewise be taken that the least dust imaginable come not to your colours while you are either painting or grinding them; for the least speck, when it is worked up with it, and when the work comes to be put into the reverberatory to be red-hot, will leave a hole, and so deface the work. When the colours are all laid, the painting must be gently dried over a slow fire to evaporate the oil, and the colours afterwards melted to incorporate them with the enamel, making the plate red-hot in a fire such as the enamellers use. Afterwards that part of the painting must be passed over again which the fire has any way effaced, strengthening the shades and colours, and committing it again to the fire, observing the same method as before, which is to be repeated till the work is finished.

The white enamel of which the glazing of fine earthenware vessels consists, is made of 100 parts of lead melted with from 15 to 40 parts of tin, and the mixture is oxydized completely, by exposing it to heat in an open vessel. One hundred parts of this oxide are mixed with an equal quantity of white sand, three parts of silica, one of talc, and 25 of common salt. This mixture is melted, then reduced to powder, and formed into a kind of paste, which is spread over the porcelain vessel before it is baked. The excellence of good enamel is, that it easily fuses into a kind of paste at the heat which is necessary for baking porcelain, and spreads equally on the vessel, forming a smooth glassy surface, without losing its opacity, or flowing completely into a glass. Its whiteness depends on the proportion of tin, and its fusibility on the lead.

Mr. Anness has just obtained a patent for enamels, of which the following are among his principal directions.

To prepare the flux or principal matter for enamelling on glass vessels.—Take one pound of saturnus glorificatus (to prepare glorificatus thus: take litharge of white lead, put it in a pan, pour on distilled vinegar, stirring it well over a gentle fire till the vinegar becomes impregnated with the salt of the lead; evaporate half the vinegar, put it in a cool place to crystallize, and keep the crystals dry for use); half a pound of natural crystal calcined to a whiteness; one pound of salt of polverine, or other fit alkali; mix them together, and bake in a slow heat for about 12 hours, then malt the mass, and pulverize the same in an agate mortar, or any other proper vessel which is not capable of communicating any metallic or other impurity.

To make green.—Take one ounce of copper-dust, two ounces of sand, one ounce of litharge, half an ounce of nitre; or two of copper, one of sand, two of litharge, one and a half of nitre, mix them with equal parts of flux, or vary the proportions of them, as may be found necessary, according to the tint of colour required.

To make black.—Take calcined iron one ounce, cobalt, crude or prepared, one ounce, or zaffer two ounces, and manganese one ounce; mixed with equal parts of flux, by melting or grinding together.

To make yellow.—Take of lead and tin ashes one ounce, litharge one ounce, antimony one ounce, sand one ounce, nitre four ounces; calcine or melt them together; pulverize and mix them with a due proportion of flux, as the nature of the glass may require; or take more or less of any or all the above, according to the depth of colour desired.

To make blue.—Take prepared cobalt one ounce, sand one ounce, red lead one ounce, nitre one ounce, flint-glass two ounces; melted together by fire, pulverized and fluxed according to the degree of softness or strength of colour required.

To make olive.—Take one ounce of the blue as prepared above, half an ounce of black, half an ounce of yellow; grind them for use; if necessary, add flux to make it softer.

To make white.—Take tin prepared by aqua-fortis one ounce, red lead one ounce, of white pebble-stone or natural crystal two ounces, nitre one ounce, arsenic one drachm, with equal parts of flux, or more or less, as the softness or opacity may require; melted, calcined, or used raw.

To make purple.—Take the finest gold; dissolve it in aqua-regia, regulated with sal ammoniac; put it in a sand-heat for about 48 hours to digest the gold, collect the powder, grind it with six times its weight of sulphur, put it into a crucible on the fire till the sulphur is evaporated, then amalgamate the powder with twice its weight of mercury, put it into a mortar or other vessel, and rub it together for about six hours, with a small quantity of water in the mortar, which change frequently; evaporate the remaining mercury in a crucible, and add to the powder ten times its weight of flux, or more or less, as the hardness or softness of the colour may require.

To make rose-colour.—Take purple as prepared above, mix it with thirty times its weight of flux, and one hundredth part of its weight of silver leaf, or any preparation of silver, or vary the proportion of the flux and silver as the quality of the colour may require; or any of the other preparations for purple will do, varying the proportion of the flux and silver as above; or any mete-

rials, from which purple can be produced, will, with the addition of silver and flux, answer.

To make brown.—Take red lead one ounce, calcined iron one ounce, antimony two ounces, litharge two ounces, zaffer one ounce, sand two ounces, calcined, or melted together, or used raw, as may be most expedient; vary the proportions of any or all the above, as tint or quality may require.

Method of application.—The aforesaid colours may be applied to vessels of glass in the following manner, viz. by painting, printing, or transfering, dipping, floating, and grounding.

To paint.—Mix the colours (when reduced by grinding to a fine powder) with spirits of turpentine, temper them with thick oil of turpentine, and apply them with camel-hair pencils, or any other proper instrument, or mix them with nut or spike oil, or any other essential or volatile oil, or with water, in which case use gum arabic, or any other gum that will dissolve in water, or with spirits, varnishes, gums of any kind, waxes, or resins; but the first is conceived to be the best.

To print.—Take a glue bat, full size, for the subject, charge the copper-plate with the oil or colour, and take the impression with the bat from the plate, which impression transfer on the glass: if the impression is not strong enough, shake some dry colour on it, which will adhere to the moist colour; or take any engraving or etching, or stamp, or cast, and having charged it with the oil or colour, transfer it on the glass by means of prepared paper, vellum, leather, or any other substance that will answer; but the first is the best. Any of the aforesaid engravings, etchings, stamps, casts, or devices, may be charged with waters, oils, varnishes, or glutinous matters of any kind, reduced to a proper state, as is necessary in printing in general; any or all of these may be used alone, or mixed with the colours. When used alone, the colour is to be applied in powder as before mentioned.

To dip.—Mix the colour to about the consistency of a cream with any of the ingredients used for printing, in which dip the glass vessel, and keep it in motion till smooth.

To ground.—First charge the glass vessel with oil of turpentine, with a camel-hair pencil, and while moist apply the colour in a dry powder, which will adhere to the oil, or, instead of oil of turpentine, use any of the materials used for printing: but the first is the best.

To float.—Mix the colour with any of the ingredients used for printing, to a consistency according to the strength of ground required, float it through a tube, or any other vessel, moving or shaking the piece of glass till the colour is spread over the part required.

ENARGEA, a genus of the hexandria monogynia class and order. There is no calyx; the petals are six; berry three-celled; four or five globular seeds. There is one species, a native of Terra del Fuego.

ENCÆNIA, the name of three several feasts celebrated by the Jews in memory of the dedication, or rather purification, of the temple, by Judas Maccabeus, Solomon, and Zorababel. This term is likewise used in church-history for the dedication of christian churches.

ENCAMPMENT, the pitching of a camp. In the regulations published by authority, are particularly enjoined the following.

Attentions relative to encampments.—On the arrival of a brigade, or a battalion, on the ground destined for its camp, the quarter and rear guards of the respective regiments will immediately mount; and when circumstances require them, the advanced picquets will be posted. The grand guards of cavalry will be formed, and the horses picketed. The men's tents will then be pitched, and till this duty is completed, the officers are on no account to quit their troops or companies, or to employ any soldier for their own accommodation. Necessaries are to be made in the most convenient situations, and the utmost attention is required in this, and every other particular, to the cleanliness of the camp.

If circumstances will allow the ground on which a regiment is to encamp to be previously ascertained, the pioneers should make these, and other essential conveniences, before the corps arrives at its encampment.

Whenever a regiment remains more than one night in a camp, regular kitchens are to be constructed. No tents, or huts, are to be allowed in front, or between the intervals of the battalions. A spot of ground for this purpose should be marked by the quarter master, with the approbation of the commanding officer.

On arriving in a camp which is intersected by hedges, ditches, unequal or boggy ground, regiments will immediately make openings of communication, of 60 feet in width. The ground in front of the encampment is to be cleared, and every obstacle to the movement of the artillery and troops is to be removed. Commanding officers of regiments must take care that their communication with the nearest grand route is open and free from impediments.

ENCANTHIS, in surgery, a tubercle arising either from the caruncula lachrymalis, or from the adjacent red skin; sometimes so large, as to obstruct not only the puncta lachrymalia, but also part of the sight or pupil itself. See SURGERY.

ENCAUSTIC, and ENCAUSTUM, the same with enamelling and enamal. See ENAMELLING, and ENAMEL.

ENCAUSTIC *painting*, a method of painting made use of by the ancients, in which wax was employed to give a gloss to their colours, and to preserve them from the injuries of the air.

This ancient art, after having been long lost, was restored by count Caylus, a member of the Academy of Inscriptions in France, and the method of painting in wax was announced to the Academy of Painting and Belles Letters, in the year 1753; though M. Bachelier, the author of a treatise De l'Histoire et du Secret de la Peinture en Cire, had actually painted a picture in wax in 1749; and he was the first who communicated to the public the method of performing the operation of inustion, which is the principal characteristic of the encaustic paintings. The count kept his method a secret for some time, contenting himself with exhibiting a picture at the Louvre in 1754, representing the head of Minerva, painted in the manner of the ancients, which excited the curiosity of the public, and was very much admired. In the interval of suspense, several attempts were made to recover the ancient method of painting. The first

scheme adopted was that of melting wax and oil of turpentine together, and using this composition as a vehicle for mixing and laying on the colours. But this method did not explain Pliny's meaning, as the wax is not burnt in this way of managing it. In another attempt, which was much more agreeable to the historian's description of encaustic painting, the wax was melted with strong lixivium of salt of tartar, and with this the colours were ground. When the picture was finished, it was gradually presented to the fire, so as to melt the wax, which was thus diffused through all the particles of the colours, so that they were fixed to the ground, and secured from the access of air or moisture. But the method of count Caylus is much more simple: the cloth or wood, which he designed for the basis of his picture, is waxed over, by rubbing it simply with a piece of bee's-wax; the wood or cloth, stretched on a frame, being held horizontally over, or perpendicularly before a fire, at such a distance, that the wax might gradually melt whilst it is rubbed on, diffuse itself, penetrate the body, and fill the interstices of the texture of the cloth, which, when cool, is fit to paint upon; but as water-colours, or those that are mixed up with common water, will not adhere to the wax, the whole picture is to be first rubbed over with Spanish chalk or white, and then colours are applied to it; when the picture is dry, it is put near the fire, whereby the wax melts, and absorbs all the colours.

Mr. J. H. Muntz, in a treatise on this subject, has proposed several improvements in the art of encaustic. When the painting is on cloth, he directs it to be prepared by stretching it on a frame, and rubbing one side several times over with a piece of bee's-wax, or virgin-wax, till it is covered with a coat of wax of considerable thickness. In fine linen, this is the only operation necessary previous to painting; but coarse cloth must be rubbed gently on the unwaxed side with a pumice stone, to take off all those knots which would prevent the free and accurate working of the pencil. Then the subject is to be painted on the unwaxed side with colours prepared and tempered with water; and when the picture is finished, it must be brought near the fire, that the wax may melt and mix and fix the colours. This method, however, can only be applied to cloth or paper, through the substance of which the wax may pass; but in wood, stone, metals, or plaister, the former method of count Caylus must be observed.

Mr. Nuntz has also discovered a method of forming grounds for painting with crayons, and fixing these, as well as water-colours, employed with the pencil. On the unwaxed side of a linen cloth, stretched and waxed as before, lay an even and thick coat of the colour proper for the ground; having prepared this colour by mixing some proper pigment with an equal quantity of chalk, and tempering them with water. When the colour is dry, bring the picture to the fire that the wax may melt, pass through the cloth, and fix the ground. An additional quantity of wax may be applied to the back of the picture, if that which was first rubbed on should not be sufficient for the body of colour; but as this must be laid on without heat, the wax should be dissolved in oil of turpentine, and applied with a brush, and the canvas be again exposed to the fire, that the fresh supply of wax may pass through the cloth, and be absorbed by the colour; and thus a firm and good body will be formed for working on with the crayons. If cloth and paper are joined together, the cloth must be first fixed to the straining frame, and then the paper must be pasted to it with a composition of paste made with wheaten flour, or starch and water, and about a twelfth part of its weight of common turpentine. The turpentine must be added to the paste when it is almost sufficiently boiled, and the composition well stirred, and left to simmer over the fire for five or six minutes; let wax be dissolved in oil of turpentine to the consistence of a thin paste; and when the cloth and paper are dry, let them be held near a fire, and with a brush lay a coat of the wax and turpentine on both sides the joined cloth and paper, to such a degree of thickness, that both surfaces may shine throughout without any appearance of dull spots. Then expose the cloth to the fire or to the sun, by which means the oil will evaporate, and the wax become solid, and be fit to receive any composition of colour proper for a ground, which is to be laid on as above directed in the case of cloth without paper.

Almost all the colours that are used in oil-painting may be also applied in the encaustic method. Mr. Muntz objects, indeed, to brown, light pink, and unburnt terra di Sienna; because these, on account of their gummy or stony texture, will not admit such a cohesion with the wax as will properly fix them; but other colours which cannot be admitted in oil-painting, as red lead, red orpiment, crystals of verdegris, and red precipitate of mercury, may be used here. The crayons used in encaustic painting are the same with those used in the common way of crayon-painting, excepting those that in their composition are too tenacious; and the method of using them is the same in both cases.

The encaustic painting has many peculiar advantages; though the colours have not the natural varnish or shining which they acquire with oil, they have all the strength of paintings in oil, and all the airiness of water-colours, without partaking of the apparent character or defects of either; they may be looked at in any light and in any situation, without any false glare: the colours are firm, and will bear washing; and a picture, after having been smoked, and then exposed to the dew, becomes as clean as if it had been but just painted. It may also be retouched at pleasure, without any detriment to the colours; for the new colours will unite with the old ones, without spots, as is the case in common size-painting; nor is it necessary to rub the places to be retouched with oil as in oil pictures; it is not liable to crack, and easily repaired if it should chance to suffer any injury. The duration of this painting is also a very material advantage; the colours are not liable to fade and change; no damp can affect them, nor any corrosive substance injure them; nor can the colour fall off in shivers from the canvas. However, notwithstanding all these and other advantages enumerated by the abbe Mazeas and Mr. Muntz, this art has not yet been much practised. Many of these properties belong to a much higher species of encaustic painting afterwards discovered in England, the colours of which are fixed by a very intense heat: nor are the colours or grounds on which they are laid liable to be dissolved or corroded by any chemical menstruum; nor, like the glassy colours of enamel, to run out of the

drawing on the fire. This method is described in the second part of the xlixth volume of the Philosophical Transactions, No. 100. Yet, notwithstanding the ingenuity of this communication, we find the ancient or some similar method of painting in wax remained a desideratum upwards of 25 years; and till a method was communicated to the Society of Arts by miss Greenland, in 1787. The ground of her information she received at Florence, through the acquaintance of an amateur of painting, who procured her the satisfaction of seeing some paintings in the ancient Grecian style, executed by signora Parenti, a professor at that place, who had been instructed by a Jesuit at Pavia, the person who made the farthest discoveries in that art. Miss Greenland's friends, knowing she was fond of painting, informed her what were the materials used, but could not tell her the proportions of the composition; however, from her anxiety to succeed in such an acquisition, she made various experiments, and at last obtained such a sufficient knowledge of the quantities of the different ingredients, as to begin and finish a picture, which she afterwards presented to the society for their inspection.

Her method is as follows: "Take an ounce of white wax, and the same weight of gum mastich powdered. Put the wax in a glazed earthen vessel over a very slow fire; and when it is quite dissolved, strew in the mastich, a little at a time, stirring the wax continually until the whole quantity of gum is perfectly melted and incorporated; then throw the paste into cold water, and when it is hard, take it out of the water, wipe it dry, and beat it in one of Mr. Wedgewood's mortars, observing to pound it at first in a linen cloth to absorb some drops of water that will remain in the paste, and would prevent the possibility of reducing it to a powder, which must be so fine as to pass through a thick gauze. It should be pounded in a cold place, and but a little while at a time, as after long beating the friction will in a degree soften the wax and gum, and instead of their becoming a powder they will return to a paste.

"Make some strong gum arabic water, and when you paint, take a little of the powder, some colour, and mix them together with the gum water. Light colours require but a small quantity of the powder, but more of it must be put in proportion to the body and darkness of the colours; and to black there should be almost as much powder as colour.

"Having mixed the colours, and no more than can be used before they grow dry, paint with fair water, as is practised in painting with water-colours, a ground on the wood being first painted of some proper colour prepared in the same manner as is described for the picture; walnut-tree and oak are the sorts of wood commonly made use of in Italy for this purpose. The painting should be very highly finished; otherwise, when varnished, the tints will not appear united.

"When the painting is quite dry, with rather a hard brush, passing it one way, varnish it with white wax, which is put into an earthen vessel, and kept melted over a very slow fire till the picture is varnished, taking great care that the wax does not boil. Afterwards hold the picture before a fire, near enough to melt the wax, but not to make it run; and when the varnish is entirely cold and hard, rub it gently with a linen cloth. Should the varnish blister, warm the picture again very slowly, and the bubbles will subside. When the picture is dirty, it need only be washed with cold water."

The opinion given by the society upon the above is, "the method made use of by miss Greenland provides against all inconveniences; and the brilliancy of the colours in the picture painted by her, and exhibited to the society, fully justifies the opinion, that the art of painting in wax, as above described, highly merited the reward of a gold pallet voted to her on this occasion."

ENCEINTE, in fortification, is the wall or rampart which surrounds a place, sometimes composed of bastions or curtins, either faced or lined with brick or stone, or only made of earth. The enceinte is sometimes only flanked by round or square towers, which is called a Roman wall.

ENCEPHALI, in medicine, worms generated in the head, where they cause so great a pain, as sometimes to occasion distraction. See MEDICINE.

ENCHASING, INCHASING, or CHASING, the art of enriching and beautifying gold, silver, and other metal work, by some design or figures represented thereon in low relievo.

Enchasing is practised only on hollow thin works, as watch-cases, cane-heads, tweezer-cases, &c. It is performed by punching or driving out the metal to form the figure from withinside, so as to stand out prominent from the plane or surface of the metal. In order to this they provide a number of fine steel blocks or puncheons, of different sizes; and the design being drawn on the surface of the metal, they apply the inside upon the heads or tops of these blocks, directly under the lines or parts of the figures; then, with a fine hammer, striking on the metal, sustained by the block, the metal yields, and the block makes an indenture or cavity on the inside, corresponding to which there is a prominence on the outside which is to stand for that part of the figure. Thus the workman proceeds to chase and finish all the parts by successive application of the block and hammer to the several parts of the design. And it is wonderful to observe with what beauty and justness, by this simple piece of mechanism, the artists in this line will represent foliages, grotesques, animals, histories, &c.

ENCHELIS, a genus of vermes infusoria. It is invisible to the naked eye, very simple, and cylindrical. There are eleven species, most of which have been described in Mr. Adam's Treatise on the Microscope.

ENCLAVE, in heraldry, denotes a thing's being let into another, especially when the piece so let in is square.

ENCLITICA, in grammar, particles which are so closely united with other words as to seem part of them, as *virumque*, &c. There are three enclitic particles in Latin, viz. *que*, *ne*, *ve*: but there are a great many in the Greek, as τε, τι, μι, μοι, σε, σοι, &c.

ENCRATITES, in church history, a sect of Christians who appeared towards the end of the second century. They were called encratites or continentes, because they gloried in abstaining from marriage, and the use of wine and animal food.

END FOR END, in the sea language, is said of a rope that has run quite out of the block wherein it was reeved.

ENDEMIC or ENDEMICAL DISEASES, those to which the inhabitants of particular countries are subject more

than others, on account of the air, water, situation, and manner of living. See MEDICINE.

ENDORSE, in heraldry, an ordinary, containing the eighth part of a pale, which Leigh says is only used when a pale is between two of them.

ENDORSED, in heraldry, is said of things borne back to back, more usually called adosse'.

ENDOWMENT, in law, denotes the settling a dower on a woman: though sometimes it is used figuratively for settling a provision upon a parson, on the building of a church; or the severing a sufficient portion of tithes for a vicar, when the benefice is appropriated.

ENEMA, in medicine, the same with clyster. See MEDICINE.

ENEMY, is properly an alien or foreigner who, in a public capacity, and in a hostile manner, invades any kingdom or country. If a prisoner is rescued by enemies, the gaoler is not guilty of an escape, as he would have been if subjects had made the rescue, when he might have a legal remedy against them. 2 Haw. 130.

ENERGUMENS, in church history, persons supposed to be possessed by the devil, concerning whom there were many regulations among the primitive Christians. They were denied baptism and the eucharist; at least this was the practice of some churches: and though they were under the care of exorcists, yet it was thought a becoming act of charity to let them have the public prayers of the church, at which they were permitted to be present.

ENFILADE, in the art of war, is used in speaking of trenches or other places which may be scoured by the enemy's shot, along their whole length. In conducting the approaches at a seige, care must be taken that the trenches be not enfiladed from any work of the place.

ENFRANCHISEMENT, the incorporating a person into any society or body politic; such is the enfranchisement of one made a citizen of London, or other city, or burgess of any town corporate, because he is made partaker of the liberties which appertain to the corporation wherein he is enfranchised.

ENGASTRIMYTHI, in Pagan theology, the Pythias or priestesses of Apollo, who delivered oracles from within, without any action of the mouth or lips.

ENGENDERING, a term sometimes used for the act of producing or forming any thing: thus worms in the abdomen are said to be engendered.

ENGINE, in mechanics, is a compound machine, consisting of one or more mechanical powers, as levers, pulleys, screws, &c. in order to raise, cast, or sustain any weight, or produce any effect which could not be easily effected otherwise. See MECHANICS.

Engines are extremely numerous; some used in war, as the battering-ram, balista, waggons, charriots, &c.; others in trade and manufactures, as cranes, mills, presses, &c.; others to measure time, as clocks, watches, &c.; and others for the illustration of some branch of science, as the orrery, cometarium, and the like.

ENGINE, *fire*, the name now commonly given to a machine by which water is thrown upon fires in order to extinguish them.

The fire-engine is properly a forcing-pump (see HYDRAULICS); and its usual construction, after the great improvements were made in it by Mr. R. Newsham, was nearly that which is exhibited in fig. 1. Plate LI. Engines, where we have represented a vertical section of the engine. The motion of the water in this machine is effected by the pressure of the atmosphere, the force of men acting upon the extremities H, H, of a lever, and thence giving motion to the pistons, and by the elasticity of condensed air, in the following manner: When the piston R is raised, a vacuum would be made in the barrel TU, if the water did not follow it from the inferior canal EM (through the valve O), which rises through the tube EF, immersed in the water of a vessel by the pressure of the atmosphere on its surface. The water of the barrel TU, by the succeeding depression of the piston R, shuts the valve O, and is forced, through the superior canal ON, to enter by the valve I into the air-vessel *abcd;* and the like being done alternately with respect to the other barrel WX, and its piston S. the air-vessel is by these means continually filling with water, which greatly compresses the air above the surface of the water in that vessel, and thereby proportionally augments its spring; which at length is so far increased as to react with great force on the surface YZ of the subjacent water, and compel it to ascend through the small tube *ef* to the stop-cock *eg*, where upon turning the cock the water is suffered to pass through a pipe *h* fixed to a ball and socket; from the orifice of which it issues in a continued stream with a great velocity, to a considerable height or distance; and it is usually kept from diverging too soon in its progress by means of a long series of flexible leather pipes, properly joined together, and known among the firemen by the name of the hose.

The greatest artifice in the engine, according to the construction just described, is the contrivance to produce a continual stream, which is done by the compression and proportional elasticity of air in the barrel *abcd*, called the air-vessel. For the air, being an elastic fluid, will be susceptible of compression in any degree by the water forced in through the valves at IK; and since the force of the air's spring will always be inversely as the space it possesses, it follows, that when the air-vessel is half full of water, the air will be compressed into half the space it possessed at first, and therefore its spring will be twice as great as at first.

But this spring at first was equal to the pressure of the atmosphere on the same surface: for if it was not, it could not have sustained or resisted the pressure of the atmosphere which stood over it, and consequently could not have filled the vessel before the water was driven in; which yet we find it did, and maintained an equilibrium with the common air. The vessel then being half-filled with water, or the air compressed into half the first space, its spring will in this case be equal to twice the pressure of the atmosphere; and therefore when the stop-cock at *p* is turned, the air within, pressing on the subjacent water with twice the force it meets with from the external air in the pipe *ef*, will cause the water to spout out of the engine to the height of 32 or 33 feet, if the friction is not too great.

When the air vessel is two-thirds full of water, the air takes up one-third part; whence its spring will be three times as great as that of the common air, and it will project the water with twice the common atmospheric pressure; consequently it will rise to the height of 62 or 64

feet. When the air-vessel is three-fourths full of water, the air will be compressed into its one-fourth part, and so will protrude the water with three times the atmospheric pressure, and carry it to the height of 96 or 99 feet. Hence it will be easy to state the law by which the spring of the air will act on the surface of the water below it, as in the following table:

Height of water in air-barrel.	Of the air compressed.	Proportion of air's elasticity.	Height of the spout.
$\frac{1}{2}$	$\frac{1}{2}$	2	33
$\frac{2}{3}$	$\frac{1}{3}$	3	66
$\frac{3}{4}$	$\frac{1}{4}$	4	99
$\frac{4}{5}$	$\frac{1}{5}$	5	132
$\frac{5}{6}$	$\frac{1}{6}$	6	165
$\frac{6}{7}$	$\frac{1}{7}$	7	198
$\frac{7}{8}$	$\frac{1}{8}$	8	231
$\frac{8}{9}$	$\frac{1}{9}$	9	264
$\frac{9}{10}$	$\frac{1}{10}$	10	297
$\frac{n-1}{n}$	$\frac{1}{n}$	n	$(n-1)\,33$

Various alterations and improvements have been made from time to time in the construction of fire-engines. The contrivers of some of these improvements, as Messrs. Bramah, Dickenson, Simpkin, Rowntree, and Philips, have secured their inventions from infringement by patents, the specifications of most of which may be seen in the Repertory of Arts and Manufactures. In the year 1785, the silver medal and 20 guineas were conferred by the Society for the Encouragement of Arts, &c. on Mr. Furst, as a reward for his contrivance to increase the effect of engines in extinguishing fires; of which the following is a short description: From a platform rises an upright pole or mast, of such height as may be judged necessary; a gaft slides upon it in an ascending direction, and along both is conveyed the leather hose from the engine. The branch or nose-pipe of the engine projects at the extremity of the gaft; towards which an iron frame is fixed, whence two chains are suspended; and from these hang ropes, which serve to give an horizontal direction to the branch; while other ropes that run through proper pulleys, and are thus conveyed down the mast, serve likewise to communicate a vertical motion to it. By these means the branch or nose-pipe of the engine is conducted into the window or any room where the fire more immediately rages; and the effect of the water discharged is applied in the most efficacious manner to the extinguishing of the flames.

A very cheap and simple fire-engine is that invented in America by Mr. Benjamin Dearborn, who communicated it to the American academy of arts and sciences, from whose Memoirs for 1794 we extract the following particulars:

Fig. 2. AB and CD are the edges of two planks, confined by four bolts; *ab* and *cd* are two cylindrical barrels, in each of which a piston, with a valve, is fastened to the spear *e*, and is moved up and down alternately by the motion of the arms EE. Beneath each barrel a hole is made through the plank AB, which is covered with a valve. The arms EE are suspended on the common centre *f*: there are also arms parallel to these on the opposite side: *gg* are the ends of handles which are fastened across the ends of the arms. At *h* a bolt goes across from arm to arm, to which the piece *ik* is affixed, and on which it plays; the lower end of this piece is fastened to the spear *e*. G *lf* is a standard for the purpose of supporting the arms, to which there is a correspondent one on the opposite side: both are notched into the edges of the planks, where they are secured by a bolt, which passes through them at *l*, and has a nut or fore-lock on the opposite side. HI, HI, are square braces, answering the purpose of ducts, through which the water ascends from the barrels, passing through the plank at *m*. KL, KL, are irons in the form of a staple, in order to confine the braces: the lower ends of these irons meet, and are secured by a bolt passing through them, and MN *uv*, which is a piece that goes up through a mortice in the centre of the planks. This piece is square from the lower end till it reaches the top of the braces; whence they become cylindrical to the top, the upper end being perforated sufficiently low down in order to communicate with the braces. OP is an iron ring that surrounds the tube, and has two shanks which ascend through the head, which screws on the top at *pq*.

Fig. 3. is the same engine; the arms and standards being taken off, in order to delineate more clearly the mode of securing the braces; an object which is completely effected by a wedge driven into the mortice *a*: beneath the upper plank *b* is a hole for admitting a passage to the bolt, which secures the standards. In this figure a side view of the head is given, with the pipe in a perpendicular direction.

The machine is confined within a box, set on wheels, as in the common fire-engines. The whole is made of wood, excepting the spears of the pumps, and a few bolts, &c. The advantages of this machine are, that it can be made in any place where common pumps are manufactured; the interior work will not exceed one-fourth of the price of those which are constructed on the usual plan; and they are incomparably more easy to work than the common ones: circumstances which strongly recommend the American fire-engine to the attention of the public.

Since the construction of engines for the extinguishing of fires has long been considered as of very great importance, it is no wonder that many persons have devoted much of their time and talents to this subject.

Engine, *pile*, a machine by which piles are driven into the earth for the foundations of piers and other structures.

In pile-engines the contrivance consists in drawing up a great weight, called a ram or hammer, to a moderate height, and then letting it fall freely with a considerable momentum upon the head of the pile. In the most simple pile-engines the ram is drawn up by men pulling at a cord running over a fixed pulley, and suffering the cord to slip from their hands when the weight is sufficiently elevated. Among the more complex engines, the best are those invented by Mr. Vauloue and by Mr. S. Bunce.

Description of Vauloue's pile-engine. (See Plate LI. Engines, fig. 4.)—A is a great upright shaft or axle, on which are the great wheel B and the drum C, turned by horses joined to the bars S,S. The wheel B turns

construction, the tumbler performs the office of the expansive force of steam at the end of the stroke.'

Mr. Boswell suggests, as a considerable improvement, that the action of this engine should be made elastic by the addition of an air-chamber, on the same principle as that used in fire-engines: this, he thinks, might be best effected by making the piston hollow, with a small orifice in the bottom, and of a larger size, to serve for this purpose, as the spring of the air would then act both on the upward and downward pressure of the water.

ENGINE, *steam*. The steam-engine is one of the noblest monuments of human ingenuity. It was originally invented by the marquis of Worcester, in the reign of Charles II. This nobleman, who appears to have been possessed of much knowledge, with a fertile imagination, published in 1663, a small book, called "A Century of Inventions," giving an account of a hundred discoveries or contrivances of his own; but the descriptions of many of them are altogether unintelligible.

Among them is an account of his invention of raising water by the force of steam, which, now that we are possessed of the engine, appears to agree very well with its construction. But as there is no plate to accompany his description, we are entirely unacquainted with the particular mode in which he applied the power of steam. It does not appear, however, that he met with sufficient encouragement; and this useful discovery was long neglected.

Towards the end of the century, captain Savary, a person of great ingenuity, having probably seen the account of the marquis of Worcester's invention, was convinced of its practicability, and succeeded in constructing a machine of this kind. He obtained a patent for the invention, and erected several steam-engines, which he described in a book entitled "The Miner's Friend," published in 1696.

The following is the description of his machine, as improved by himself:

a (Plate LII. fig. 1) is a strong boiler, built in a furnace for generating steam. From the top of this boiler there proceeds a pipe, b, which conveys the steam into another strong vessel, r, called the receiver. This pipe has a cock at c, called the steam-cock. In the bottom of the receiver is a pipe s, which communicates with the rising-pipe H n k, the lower end of which is immersed in the well from which the water is to be raised. Immediately below the place where the pipe s enters the rising-pipe, there is a valve, n, opening upwards. A similar valve is also placed at i, above the pipe S. Lastly, there is a pipe e, which branching off from the rising-pipe, enters the top of the receiver. This pipe has also a cock, d, called the injection-cock. The mouth of the pipe e, has on the end f a nozzle, pierced full of holes, pointing from a centre in every direction. The keys of the two cocks c and d, are united by the handle h, called the regulator.

The mode of operation is as follows: Let the regulator be so placed, that the steam-cock c be open, and the injection-cock d shut: put water into the boiler a, and make it boil. The steam from it will enter the pipe b, and fill the receiver, first driving out the air which it before contained; a considerable quantity of steam will be at first condensed by the cold sides of the receiver; but it being at length warmed, the steam will proceed into the rising-pipe, lifting up the valve i. When this is perceived to be the case, by the rising-pipe feeling warm, and hearing the valve i rattle, the communication is now to be cut from the boiler, by shutting the steam-cock c, the injection cock d being also shut. The receiver now gradually cools, and the steam included in it condenses into water. When this is the case, as the air was at first driven out by the steam, and cannot return again, all the cocks being shut, a vacuum is formed in the receiver; consequently, there is nothing to counterbalance the pressure of the atmosphere, which acting upon the water in the well, forces it up the rising-pipe, and fills the receiver. The steam-cock is now opened; and the steam from the boiler rushing in with great violence, presses upon the surface of the water in the receiver, and forcing it through the pipe s, into the rising-pipe, causes it to shut the valve n, and open the other valve i; and, provided the steam be sufficiently strong, will force it up the rising-pipe to the top k, where it is delivered. The cock c is kept open until all the water be driven out of the receiver, and it is again filled with steam. The regulator is now applied, which shuts the steam-cock, whilst at the same time it opens the injection-cock. The rising-pipe being still full of water, a stream of cold water proceeds through the pipe e, and enters the receiver in a shower. This instantly condenses the steam in the receiver, and produces a vacuum as before; in consequence of which, the water from the well is again forced up by the external pressure of the atmosphere, and the receiver is again filled with water. The regulator is then turned, which shuts the injection-cock and opens the steam-cock, which permits the steam from the boiler to press upon the water, and again force it up the rising-pipe. This operation filling the receiver with water by means of a vacuum produced in it, and forcing it up the rising-pipe by the pressure of the steam from the boiler, is constantly repeated, by merely turning the regulator, which shuts and opens the steam-cocks and injection-cocks alternately.

This construction of the steam-engine is extremely simple, and might perhaps be successfully applied for some purposes. But it has several considerable defects. It may readily be apprehended, that the action of the direct steam on any definite surface (such, for example, as a square inch) will be exactly equal to the re-action of the water which is forced up; and consequently, that Savary's engine will require steam more elastic than the air of the atmosphere, in every case except where the water is raised no higher than it can be by the vacuum that is produced, and the pressure of the atmosphere. When the water is forced up through the rising-pipe, every square inch of the boiler must sustain a pressure equal to a column of water an inch square, and of the height of the pipe above the boiler. This, therefore, requires very strong vessels, and several accidents happen by their bursting when the safety valve is loaded too much.

But the greatest defect of this machine is the great waste of steam, and consequently of fuel. For when the steam is admitted to the top of the cold water in the receiver, it is condensed with great rapidity; and the water does not begin to yield to its pressure, until its sur-

face is so hot, as not to condense any more steam: it now descends; but as by that, a new part of the side of the receiver is exposed to the steam, more is condensed, so that a consideration of the steam is going on all the while the water is descending. This too must necessarily be repeated every stroke, as the receiver is cooled every time it is filled with water.

Mr. Savary succeeded in raising water to small heights, and erected several engines in different parts of England; but he could make nothing of deep mines. Many attempts have been made to correct these defects, but hitherto without much success.

In the beginning of the eighteenth century, Newcomen, an ironmonger or smith, and Cranly, a glazier at Dartmouth, in Devonshire, first conceived the project of applying a piston with a lever, and other machinery. They were contented to share the profits of the invention with Savary, who procured a patent for it in 1705, in which they were all three joined.

Fig. 2, exhibits a section of Newcomen's engine: *a* is the boiler, built in brick-work. In the top of the boiler is a steam-pipe, *c*, communicating with the cylinder, *b*, which is of metal, and is bored very truly. The lower aperture of this pipe is shut by the plate *n*, which is ground very flat, so as to apply very accurately to the whole circumference of the orifice. This plate is called the regulator, or steam-cock, and it turns horizontally round an axis *o*, which passes through the top of the boiler, and is fitted by grinding to the socket, so as to be steam-tight. It is opened and shut by a handle fixed to its axis.

In the cylinder *b* is a solid piston, *p*, well fitted into it, and made air-tight by a packing of leather or soft rope, well filled with tallow; and for greater security, a small quantity of water is kept above the piston.

The piston-rod *d* is suspended by a chain, which is fixed to the upper extremity of the arched head *e* of the great lever, or working-beam, *e f g*, which turns on the gudgeon *f*. There is a similar arched head *g*, at the other end of the beam; to the upper extremity of which is fixed a chain, carrying the pump-rod *h*, which raises the water from the mine.

The load on this end of the beam is made to exceed considerably the weight of the piston at the other extremity.

At a small height above the top of the cylinder, is a cistern called the injection-cistern. *i*. From this descends the injection-pipe, *k*, which enters the bottom of the cylinder, and terminates in a nozzle pierced with holes. This pipe has a cock, *l*, called the injection-cock.

At the opposite side of the cylinder, a little above its bottom, there is a lateral pipe *m*, turning upwards at the extremity; and there covered by a clack-valve, called the snifting-valve, which has a little dish round it, to hold water for keeping it air-tight.

There proceeds also from the bottom of the cylinder, a pipe *g*, of which the lower end is turned upwards, and is covered with a valve *r*. This part is immersed in a cistern of water, called the hot-well, and the pipe itself is called the eduction-pipe.

Lastly, the boiler I. furnished with a safety valve, called the puppet-clack, in the same manner as in Savary's engine. This valve is generally loaded with one or two pounds in the square inch, so that it allows the steam to escape when its elasticity is one-tenth greater than that of the atmosphere. Thus all risk of bursting the boiler is avoided, the pressure outwards being very moderate.

When the cistern for the injection-water *i*, cannot be supplied by pipes from some more elevated source, water is raised by the machine itself. A small lifting-pump, *s*, is worked by a rod *v*, suspended from a small arch upon the great beam; this forces water through the pipe *t* into the injection-cistern.

The parts of the engine being now described, the operation is as follows:

Suppose the piston and lever in the position represented in the plate, and the water in the boiler in a state of ebullition, the steam and injection-cocks being shut. Having opened the steam-cock, *n*, the steam from the boiler will immediately rush in, and flying all over the cylinder, will mix with the air.

Much of it will be condensed by the cold surface of the cylinder and piston, and the water produced from it will trickle down the sides, and run off by the eduction-pipe. This condensation and waste of steam will go on until the whole cylinder and piston be made as hot as boiling-water.

When this happens, the steam will begin to issue through the snifting-valve, slowly at first, and cloudy, being mixed with much air; but, by degrees, it will become more transparent, having carried off the greatest part of the air which filled the cylinder.

When the attendant perceives that the blast at the snifting-valve is strong and steady, and the boiler is supplied with a steam of proper strength, appearing by the renewal of its discharge at the safety-valve, which had stopped while the cylinder was filling, he shuts the steam-cock, *n*, and opens the injection-cock, *l*. The pressure of water in the injection-pipe forces some out into the cylinder, which condenses the steam and forms a partial vacuum, as explained above.

The upper side of the piston is now exposed to the whole pressure of the atmosphere, which, not being counterbalanced on the under side, will act with its whole force on the piston, and, provided there be not too much weight on the other end, will raise it, the piston going to the bottom of the cylinder.

When the piston has gone down as low as necessary, the injection-cock is shut, and the steam-cock opened. The steam, which has been accumulating above the water in the boiler, during the time of the descent of the piston, and is now issuing through the puppet-clack, as soon as the steam-cock is opened, rushes violently into the cylinder, having a greater elasticity than that of the air. It therefore immediately blows open the snifting-valve, through which it drives out the air that had been disengaged from the injection-water.

At the same time, the water which had been injected before, and the condensed steam, run out through the eduction-pipe, *g*, and lifting up the valve, *r*, flow into the hot-well.

By the admission of the steam under the piston, the pressure of the atmosphere on the top is counterbalanced, and the piston is free to move upwards or downwards.

But the other end of the beam being broader, so as to be heavier than the piston, now raises it to the top of the

at first a little confused, by there seeming to be only one steam-pipe for communicating between the cylinder and the condenser; but the difficulty is cleared up, by representing both the pipes, as in fig. 4.

Fig. 5, is a longitudinal section of the boiler, representing the mode of supplying it with water, and the safety-valve and cocks. f is a small cistern, which is supplied with water from the hot-well, as represented in fig. 3; from the bottom of this cistern, a pipe goes down almost to the bottom of the boiler, where it turns up a little, to prevent the entrance of the steam which rises from the bottom. From the side of this cistern, is supported a small lever, to one end of which is fastened a wire, that carries a stone which hangs in the water of the boiler; the other end of the lever supporting also by a wire, a valve that shuts the top of the pipe that goes down from the cistern. Now, supposing the stone just at the surface of the water, and balanced by a weight at the opposite end of the lever; it is evident, that by the laws of hydrostatics, already explained, a certain part of the weight of the stone will be supported by the water, so long as it continues immersed in it; but if a part of the water evaporate by boiling, a proportional part of the stone will be above the water, consequently the stone will bear more upon the lever, and raise the weight at the other end; but in raising that weight, it also opens the valve in the small cistern, and admits water until it stand at the same height in the boiler as before, and then the valve and the stone being again in equilibrio, the valve remains shut until a new quantity is evaporated. By this means the supply of water is very gradual, however, and not by fits and starts, as here described for the sake of illustration.

It is found by experience, to be a much better method than a ball-cock, and the regular supplying of the boiler with water is of the first importance. As a check upon this, and to know perfectly the height of the water in the boiler, there are two cocks, g and h, one of which reaches nearly to the surface of the water when at its proper height, and the other enters a little below the surface.

It is evident, that if the water be at the just height, and you open *g*, steam will issue; and if *h* be opened, water will be driven out by the pressure of the steam. But if water come out from *g*, then the water must be too high in the boiler; and if steam issue from h, then the water is too low. By this means, it is easy to know at all times the exact height of the water in the boiler.

i is a safety-valve, to prevent the bursting of the boiler by the steam growing too strong; *k* is the pipe which conveys the steam to the engine.

Fig. 6 is Mr. Cartwright's steam-engine, the construction of which evinces much ingenuity. *a* is the cylinder, which is supplied with steam from the boiler through the pipe *b*; *c* is the piston in the act of going up; *d* is the pipe that conducts the steam into the condenser *e*, which consists of two cylinders, one within the other, leaving a small space between them, into which the steam is admitted; while the inner cylinder is filled with cold water, and also the external cylinder surrounded by the same; so that, by this means, a very large surface of steam is exposed, though no water is suffered to come into actual contact with it.

To the bottom of the piston, *c*, is attached a rod, with another piston, *e*, working in the pipe *d*. When the piston *e* arrives at the bottom of the cylinder, a valve which is in the piston, is opened by its pressing against the bottom, and opens a communication with the condenser, whilst the spring *k*, fixed to the rod of the piston, shuts the valve, which admits the steam from the boiler. The steam, therefore, being thus condensed, runs into the lower pipe *f*. The piston *e*, arriving at the bottom of the pipe in which it works at the same time with c, presses upon the condensed water, shuts the valve *f*, and forces the water up the pipe *g*, into the box *h*. The air which is disengaged from the water, rises to the top of the box, and, by its elasticity, forces the water through the pipe *i*, which carries it back again into the boiler. When the air accumulates in the box to such a degree as to depress the water, the ball-cock falls with it, and opens a valve in the top of the box, which suffers some of the air to escape.

When all the steam is condensed, the motion of the fly attached to the machine brings the piston up again, its valve now remaining shut by its weight. On arriving at the top, it presses up the steam-valve, which admits the steam from the boiler to force it down as before.

l and *m* are two cranks, upon whose axis are two equal wheels working in each other, for the purpose of converting the perpendicular motion of the piston-rod into a rotatory motion, for working the machinery attached to it.

But the most valuable part of this engine is in the construction of the piston, which Mr. Cartwright made wholly of metal, and so as, by means of springs, to fit the cylinder very exactly. This not only saves the expense and trouble of packing, which they are obliged frequently to renew in all other engines, but also saves a great deal of steam, on account of the more accurate fitting of the piston.

As it is evident, from its construction, that the whole of the steam is brought back again into the boiler, it affords the means of employing ardent spirit instead of water, and thus saving a great deal of fuel.

This machine seems to be peculiarly applicable to purposes requiring only a small power, as it is not expensive, and occupies little room.

It would far exceed the limits of this work, to enter into an examination of all the steam-engines invented by different persons. It is sufficient to mention, that no engine of this kind has been found, upon careful trial, to be superior to those of Mr. Watt.

From this brief description of the steam-engine, the reader will be enabled to perceive the nature, and appreciate the value, of Mr. Watt's improvements. It had hitherto been the practice to condense the steam in the cylinder itself, by the injection of cold water; but the water which is injected acquires a considerable degree of heat from the cylinder, and being placed in air highly rarefied, part of it is converted into steam, which resists the piston, and diminishes the power of the engine. When the steam is next admitted, part of it is converted into water by coming in contact with the cylinder, which is of a lower temperature than the steam, in consequence of the destruction of its heat by the injection-water. By condensing the steam, therefore, in the cylinder itself, the

resistance to the piston is increased by a partial reproduction of this elastic vapour, and the impelling power is diminished by a partial destruction of the steam which is next admitted. Both these inconveniences Mr. Watt has in a great measure avoided, by using a condenser separate from the cylinder, and encircled with cold water; and by surrounding the cylinder with a wooden case, and interposing light wood-ashes, in order to prevent its heat from being abstracted by the ambient air.

The greatest of Mr. Watt's improvements consists in his employing the steam both to elevate and depress the piston. In the engines of Newcomen and Beighton, the steam was not the impelling power: it was used merely for producing a vacuum below the piston, which was forced down by the pressure of the atmosphere, and elevated by the counterweight at the farther extremity of the great beam. The cylinder, therefore, was exposed to the external air at every descent of the piston, and a considerable portion of its heat being thus abstracted, a corresponding quantity of steam was of consequence destroyed. In Mr. Watt's engines, however, the external air is excluded by a metal plate at the top of the cylinder, which has a hole in it for admitting the piston-rod; and the piston itself is raised and depressed merely by the force of steam.

When these improvements are adopted, and the engine is constructed in the most perfect manner, there is not above $\frac{1}{4}$ part of the steam consumed in heating the apparatus; and, therefore, it is impossible that the engine can be rendered $\frac{1}{4}$ more powerful than it is at present. It would be very desirable, however, that the force of the piston could be properly communicated to the machinery without the intervention of the great beam. This, indeed, has been attempted by Mr. Watt, who has employed the piston-rod itself to drive the machinery; and Mr. Cartwright has, in his engine, converted the perpendicular motion of the piston into a rotatory motion, by means of two cranks fixed to the axis of two equal wheels which work in each other. Notwithstanding the simplicity of these methods, none of them have come into general use; and Mr. Watt still prefers the intervention of the great beam, which is generally made of hard oak, with its heart taken out, in order to prevent it from warping. A considerable quantity of power, however, is wasted by dragging, at every stroke of the piston, such a mass of matter from a state of rest to a state of motion, and then from a state of motion to a state of rest. To prevent this loss of power, a light frame of carpentry has been employed by several engineers, instead of the solid beam; but after being used for some time, the wood was generally cut by the iron bolts, and the frame itself was often instantaneously destroyed. In some of the engines lately constructed by Mr. Watt, he has formed the great beam of cast iron, and while he has thus added to its durability, he has at the same time diminished its weight and increased the power of his engine.

Encouraged by Mr. Watt's success, several improvements upon the steam-engine have been attempted by Hornblower, Trevethick, and many other engineers in England. But it does not appear that they have either increased the power of the engine, or diminished its expense. It appears, on the contrary, that many of these pretended improvements, excepting those of Hornblower, consist merely in having adopted Mr. Watt's discoveries, in such a manner as not to infringe upon his patent.

Some time since, Mr. Arthur Woolf announced to the public a discovery respecting the expansibility of steam, which promises to be of very essential utility. Mr. Watt had formerly ascertained, that steam which acts with the expansive force of four pounds per square inch, against a safety valve exposed to the weight of the atmosphere, after expanding itself to four times the volume it thus occupies, is still equal to the pressure of the atmosphere. But Mr. Woolf has gone much farther, and has proved, that quantities of steam, having the force of 5, 6, 7, 8, 9, 10, &c. pounds on every square inch, may be allowed to expand 5, 6, 7, 8, 9, 10, &c. times its volume, and will still be equal to the atmosphere's weight, provided that the cylinder in which the expansion takes place, has the same temperature as the steam before it began to expand. It is evident, however, that an increase of temperature is necessary both to produce and to maintain this augmentation of the steam's expansive force above the pressure of the atmosphere. At the temperature of 212° of Fahrenheit, the force of steam is equal only to the pressure of the atmosphere: and in order to give it an additional elastic force of five pounds per square inch, the temperature must be increased to about 227$\frac{1}{2}$°; when it will have acquired a power to expand itself to five times its volume, and still be equal in pressure to the atmosphere, and capable of being applied as such in the working of steam-engines, according to his invention. The ratio of other pressures, temperatures, and expansive forces of steam, is shown in the following table; which gives the relative pressure per square inch, temperatures, and expansibility of steam, at degrees of heat above the boiling point of water; beginning with a temperature of steam of an elastic force equal to five pounds per square inch, and extending to steam able to sustain forty pounds on the square inch.

Table of the pressures, temperatures, and expansibility of steam, equal to the force of the atmosphere.

Elastic force of steam predominating over the pressure of the atmosphere, and acting upon a safety valve.	Degrees of temperature requisite for bringing the steam to the different expansive forces in the preceding column	No. of times its volume that steam of the preceding force and temperature will expand, and still continue equal to the pressure of the atmosphere.
Pounds per square inch	Degrees of heat.	Expansibility.
5	227$\frac{1}{2}$	5
6	230$\frac{1}{4}$	6
7	232$\frac{3}{4}$	7
8	235$\frac{1}{4}$	8
9	237$\frac{1}{2}$	9
10	239$\frac{1}{2}$	10
15	250$\frac{1}{2}$	15
20	259$\frac{1}{2}$	20
25	267	25
30	273	30
35	278	35
40	282	40

In this manner, by small additions of temperature, an expansive power may be given to steam, which will enable it to expand 50, 100, 200, 300, &c. times its volume, and still have the same force as the atmosphere.

Upon this principle Mr. Woolf has taken out a patent for various improvements on the steam-engine, a short account of which we shall subjoin in the words of the specification.

"If the engine be constructed originally with the intention of adopting the preceding improvement, it ought to have two steam-vessels of different dimensions, according to the expansive force to be communicated to the beam, for the smaller steam-cylinder must be a measure for the larger. For example, if steam of 40 pounds the square inch is fixed on, then the smaller steam-vessel should be at least one-fortieth part the contents of the larger one. Each steam-vessel should be furnished with a piston, and the smaller cylinder should have a communication both at its top and bottom, with the boiler which supplies the steam, which communications, by means of cocks or valves, are to be alternately opened and shut during the working of the engine. The top of the small cylinder should have a communication with the bottom of the larger cylinder, and the bottom of the smaller one with the top of the larger, with proper means to open and shut these alternately by cocks, valves, or any other contrivance. And both the top and bottom of the larger cylinder should, while the engine is at work, communicate alternately with a condensing vessel, into which a jet of water is admitted to hasten the condensation. Things being thus arranged, when the engine is at work, steam of a high temperature is admitted from the boiler to act by its elastic force on one side of the smaller piston, while the steam which had last moved it has a communication with the larger cylinder, where it follows the larger piston now moving towards that end of its cylinder which is open to the condensing vessel. Let both pistons end their stroke at one time, and let us now suppose them both at the top of their respective cylinders ready to descend; then the steam of 40 pounds the square inch, entering above the smaller piston, will carry it downwards, while the steam below it, instead of being allowed to escape into the atmosphere, or applied to any other purpose, will pass into the larger cylinder above its piston, which will take its downward stroke at the same time that the piston of the smaller cylinder is doing the same thing; and, while this goes on, the steam which last filled the larger cylinder, in the upward stroke of the engine, will be passing into the condenser, to be condensed in the downward stroke. When the pistons in the smaller and larger cylinder have thus been made to descend to the bottom of their cylinders, then the steam from the boiler is to be shut off from the top, and admitted to the bottom of the smaller cylinder, and the communication between the bottom of the smaller, and the top of the larger cylinder, is also to be cut off, and the communication to be opened between the top of the smaller and the bottom of the larger cylinder; the steam which, in the downward stroke of the engine, filled the larger cylinder, being now opened to the condenser, and the communication between the bottom of the larger cylinder and the condenser cut off; and so on alternately, admitting the steam to the different sides of the smaller piston, while the steam last admitted into the smaller cylinder passes alternately to the different sides of the larger piston in the larger cylinder, the top and bottom of which are made to communicate alternately with the condenser.

"In an engine where these improvements are adopted, that waste of steam which arises in other engines from steam passing the piston, is totally prevented, for the steam which passes the piston in the smaller cylinder is received into the larger."

Mr. Woolf has also shown how the preceding arrangement may be altered, and has pointed out various other modifications of his invention, and the method of applying his improvements to steam-engines which are already constructed.

On the power of steam-engines, and the method of computing it.—From the account which has been given of the steam-engine, and the mode of its operation, it must be evident that its power depends upon the breadth and height of the cylinder, or, in other words, on the area of the piston and the length of its stroke. If we suppose that no force is lost in overcoming the inertia of the great beam, and that the lever by which the power acts is equal to the lever of resistance; then, if steam of a certain elastic force is admitted above the piston, so as to press it downwards with a force of a little more than 100 pounds, it will be able to raise a weight of 100 pounds hanging at the end of the great beam. When the piston has descended to the bottom of the cylinder, through the space of four feet, the weight will have risen through the same space; and 100 pounds raised through the height of four feet, during one descent of the piston, will express the mechanical power of the engine. But if the area of the piston, and the length of the cylinder, are doubled, while the expansive force of the steam, and the time of the piston's descent, remain the same, the mechanical energy of the engine will be quadruple, and will be represented by 200 pounds raised through the space of eight feet during the time of the piston's descent. The power of steam-engines therefore is, cæteris paribus, in the compound ratio of the area of the piston, and the length of the stroke. These observations being premised, it will be easy to compute the power of steam-engines of any size.

Thus, let it be required to determine the power of steam-engines, whose cylinder is twenty-four inches diameter, and which make twenty-two double strokes in a minute, each stroke being five feet long, and the force of the steam being equal to a pressure of twelve pounds avoirdupois upon every square inch. The diameter of the piston being multiplied by its circumference, and divided by four, will give its area in square inches; thus $\frac{24 \times 3.1416 \times 24}{4} = 452.4$ the number of square inches exposed to the pressure of the steam. Now if we multiply this area by twelve pounds, the pressure upon every square inch, we shall have $452.4 \times 12 = 5428.8$ pounds, the whole pressure upon the piston, or the weight which the engine is capable of raising. But since the engine performs 22 double strokes, five feet long, in a minute, the piston must move through $22 \times 5 \times 2 = 220$ feet in the same time; and therefore the power of the engine will be represented by 5428.8 pounds avoirdupois, raised through 220 feet in a minute; or by 10.4 hogsheads

of water, ale measure, raised through the same height in the same time. Now this is equivalent to $5428.8 \times 220 = 1194336$ pounds, or $10.4 \times 220 = 2288$ hogsheads raised through the height of one foot in a minute. This is the most unequivocal expression of the mechanical power of any machine whatever, that can possibly be obtained. But as steam-engines were substituted in the room of horses, it has been customary to calculate their mechanical energy in horse-powers, or to find the number of horses which could perform the same work. This indeed is a very vague expression of power, on account of the different degrees of strength which different horses possess. But still, when we are told that a steam-engine is equal to 16 horses, we have a more distinct conception of its power, than when we are informed that it is capable of raising a number of pounds through a certain space in a certain time.

Messrs. Watt and Boulton suppose a horse capable of raising 32,000 pounds avoirdupois, one foot high in a minute, while Dr. Desaguliers makes it 27,500 pounds, and Mr. Smeaton only 22,916. If we divide, therefore, the number of pounds which any steam-engine can raise one foot high in a minute, by these three numbers, each quotient will represent the number of horses to which the engine is equivalent. Thus in the present example, $\frac{1194336}{32000} = 37\frac{1}{3}$ horses according to Watt and Boulton; $\frac{1194336}{27500} = 43\frac{1}{3}$ horses, according to Desaguliers; and $\frac{1194336}{22916} = 52\frac{1}{7}$ horses, according to Smeaton. In this calculation it is supposed that the engine works only eight hours a day: so that if it wrought during the whole 24 hours, it would be equivalent to thrice the number of horses found by the preceding rule. We cannot help observing, and it is with sincere pleasure that we pay that tribute of respect to the honour and integrity of Messrs. Watt and Boulton which has every where been paid to their talents and genius,—that in estimating the power of a horse, they have assigned a value the most unfavourable to their own interests. While Mr. Smeaton and Dr. Desaguliers would have made the engine in the preceding example equivalent to 52 or 43 horses, the patentees themselves state that it will perform the work only of 37. How unlike is this conduct to some of our modern inventors, who ascribe powers to their machines which cannot possibly belong to them, and employ the meanest arts for ensnaring the public!

Before we conclude this article, we shall state the performance of some of these engines, as determined by experiment. An engine whose cylinder is 31 inches in diameter, and which makes 17 double strokes per minute, is equivalent to 40 horses, working day and night, and burns 11,000 pounds of Staffordshire coal per day. When the cylinder is nineteen inches, and the engine makes 25 strokes of 4 feet each per minute, its power is equal to that of 12 horses working constantly, and it burns 3,700 pounds of coals per day. And a cylinder of 24 inches which makes 22 strokes of 5 feet each, performs the work of 20 horses, working constantly, and burns 5,500 pounds of coals. Mr. Boulton has estimated their performance in a different manner. He states, that one bushel of Newcastle coals, containing 84 pounds, will raise 30 million pounds one foot high; that it will grind and dress eleven bushels of wheat; that it will slit and draw into nails 5 cwt. of iron; that it will drive 1000 cotton spindles, with all the preparation machinery, with the proper velocity; and that these effects are equivalent to the work of 10 horses.

ENGINE *to lower heavy weights.* This method was described nearly a century ago, and is as follows: Suppose it was required to lower large stones from a building; erect a frame A, set up a gin close by the side of the wall, and let the pulley (Plate LI. Engines, fig. 9.) be firmly attached to this frame. Over this pulley must pass a cord, one end of which C has a hook to which the stone or other weight can be fastened: the other end D carries a vessel, which may be filled with water from the reservoir M on the ground at the bottom of the wall. Then, while one man is fixing the stone to the hook at the top of the wall, let another put water into the vessel D at the bottom till it nearly equals the weight of the stone; after which the stone will gradually descend to the ground, while the vessel D will be carried up to the funnel S, into which the water may be poured, and thence conveyed by a wooden or leathern pipe to M. Then the vessel D may be suffered to descend, and the hook C will be raised to be fixed to another stone, and thus the operation may be repeated.

The same method may be adopted in lowering sacks from a granary, &c. The velocity of the descending weight may be so regulated as to have any proportion to that which gravity imparts to bodies falling freely: thus if W = weight to be lowered, V that of the vessel of water, then $\frac{W-V}{W+V}$ expresses the ratio of the velocity, to that freely imparted by gravity when denoted by unity: thus if $V = \frac{W}{2}$, the weight will fall through $\frac{1}{3}$ of $16\frac{1}{12}$, or about $5\frac{1}{3}$ feet in the first second: if $V = \frac{2W}{3}$, the weight will fall through $\frac{1}{5}$ of $16\frac{1}{12}$ or $3\frac{1}{2}$ feet, the friction not being taken into consideration.

ENGINES, in military mechanics, are compound machines, made of one or more mechanical powers, as levers, pulleys, screws, &c. in order to raise, project, or sustain, any weight, or produce any effect which could not be easily effected otherwise.

ENGINE *to drive fuses*, consists of a wheel with a handle to it, to raise a certain weight, and to let it fall upon the driver, by which the strokes become more equal.

ENGINE *to draw fuses*, has a screw fixed upon a three-legged stand, the bottom of which has a ring to place it upon the shell; and at the end of the screw is fixed a hand-screw by means of a collar, which being screwed on the fuse, by turning the upper screw, draws out or raises the fuse.

ENGINEER, is commonly applied to an officer who is appointed to inspect and contrive any attacks, defences, &c. of a fortified place, or to build or repair them, &c.

The art of fortification is an art which stands in need of so many others, and whose object is so extensive, and its operations accompanied with so many various

circumstances, that it is almost impossible for a man to make himself master of it by experience alone, even supposing him born with all the advantages of genius and disposition possible for the knowledge and practice of that important art. We do not pretend to deny that experience is of greater efficacy than all the precepts in the world; but it has likewise its inconveniences as well as its advantages: its fruits are of slow growth; and whoever is content with pursuing only that method of instruction, seldom knows how to act upon emergencies of all kinds, before old age incapacitates him from exercising his employment. Experience teaches us through the means of the errors we commit ourselves, what theory teaches us at the expense of others. The life of man being short, and opportunities of practice seldom happening, it is certain nothing less than a happy genius, a great share of theory, and intense application joined to experience, can make an engineer expect to shine in his profession. Whence it follows, that less than the three first of those four qualities should not be a recommendation for the reception of a young gentleman into the corps of engineers.

The fundamental sciences, or those absolutely necessary, are arithmetic, geometry, mechanics, hydraulics, and drawing. Without arithmetic, it is impossible to make a calculation of the extent, and to keep an account of the disbursements made or to be made; nor without it can an exact computation be made upon any occasion whatsoever. Without geometry, it is impossible to lay down a plan or map with truth and exactness, or settle a draught of a fortification, or calculate the lines and angles, so as to make a just estimation, in order to trace them on the ground, and to measure the surface and solidity of their parts. Mechanics teach us the proportions of the machines in use, and how to increase or diminish their powers as occasion may require; and likewise to judge whether those which our own imagination suggests to us will answer in practice. Hydraulics teaches us how to conduct waters from one place to another, to keep them at a certain height, or to raise them higher. How fluently soever we may express ourselves in speaking or writing, we can never give so perfect an idea as by an exact drawing; and often in fortification both are wanted, for which reason the art of drawing is indispensably necessary for engineers.

To the qualities above mentioned must be added activity and vigilance; both which are absolutely necessary in all operations of war, but especially in the attack of such places as are in expectation of succours. The besieged must have no time allowed them for consideration; one hour lost at such a juncture often proves irreparable. It is by their activity and vigilance, that engineers often bring the besieged to capitulate much sooner than they would have done if those engineers had not pushed on the attack with firmness and resolution. Want of vigilance and activity often proceed from irresolution, and that from weakness of capacity.

As the office of an engineer requires great natural qualifications, much knowledge, study, and application, it is but reasonable that the pay should be proportioned to that merit which is to be the qualification of the person employed: he must be at an extraordinary expense in his education, and afterwards for books and instruments for his instruction and improvement, as well as for many other things; and that he may be at liberty to pursue his studies with application, he must not be put to shifts for necessaries. It should likewise be considered, that if an engineer does his duty, be his station what it will, his fatigue must be very great; and to dedicate himself wholly to that duty, he should be divested of all other cares.

The word engineer is of modern date, and was first used about the year 1650, when captain Thomas Rudd had the title of chief engineer to the king. In 1600, the title given to engineers was trench-master; and in 1622, sir William Pelham, and after him sir Francis Vere, acted as trench-masters in Flanders. In the year 1634, an engineer was called camp-master general, and sometimes engine-master; being always subordinate to the master of the ordnance.

At present the corps of royal engineers in England consists of one colonel in chief, one colonel en second, one chief engineer, five colonels, six lieutenant-colonels, 18 captains, 15 captain-lieutenants and captains, 31 lieutenants, and 16 second lieutenants. The establishment of the corps of invalid engineers, comprises a colonel, lieutenant-colonel, captain, captain-lieutenant and captain, first lieutenant, and second lieutenant.

The corps of royal engineers in Ireland consits of a director, colonel, lieutenant-colonel, major, captain, captain-lieutenant and captain, and two first lieutenants.

ENGRAILED, or Ingrailed, in heraldry, a term derived from the French *grele*, hail; and signifying a thing the hail has fallen upon and broke off the edges, leaving them ragged, or with half-rounds or semicircles struck out of their edges.

ENGRAVING, the art of cutting wood, metals, and precious stones, and representing thereon figures, letters, or whatever device or design the artist fancies.

Engraving, properly a branch of sculpture, is divided into several other branches, according to the matter whereon it is employed, and the manner of performing it.

Engraving, or *graving* as it is generally called, is the cutting lines upon a copper-plate, by means of a steel instrument, called a graver, without the use of aqua fortis.

This was the first mode of producing copper-plate prints that was practised; and is still much used in historical subjects, portraits, and in finishing landscapes.

The tools necessary for this art are, gravers, a scraper, a burnisher, an oil-stone, a sand-bag or cushion, an oil-rubber, and some good charcoal.

The gravers are instruments of tempered steel, fitted into a short wooden handle. They are of two sorts, square and lozenge: the first is used in cutting very broad strokes, the other for fainter and more delicate lines.

The scraper is a three-edged tool, for scraping off the burr raised by the graver. Burnishers are for rubbing down any lines that are too deep, or burnishing out any scratches or holes in the copper: they are of very hard steel, well rounded and polished.

The oil-stone is for whetting the gravers, etching-points, &c.

The sand-bag, or cushion, is for laying the plate upon,

for the convenience of turning it round in any direction.

The oil-rubber and charcoal, are for polishing the plate when necessary.

As great care is required to whet the graver nicely, particularly the belly of it, care must be taken to lay the two angles of the graver, which are to be held next the plate, flat upon the stone, and rub them steadily, till the belly rises gradually above the plate; so that, when you lay the graver flat upon it, you may just perceive the light under the point; otherwise it will dig into the copper, and then it will be impossible to keep a point, or execute the work with freedom. In order to this, keep your right arm close to your side, and place the fore-finger of your left hand upon that part of the graver which lies uppermost on the stone. When this is done, in order to whet the face, place the flat part of the handle in the hollow of your hand, with the belly of the graver upwards, upon a moderate slope; and rub the extremity, or face, upon the stone, till it has an exceedingly sharp point, which you may try upon your thumb-nail.

When the graver is too hard, as is usually the case when first bought, and may be known by the frequent breaking of the point, the method of *tempering* it is as follows: Heat a poker red-hot, and hold the graver upon it, within half an inch of the point, till the steel changes to a light straw-colour; then put the point into oil, to cool: or, hold the graver close to the flame of a candle, till it be of the same colour, and cool it in the tallow; but be careful either way, not to hold it too long, for then it will be to soft; and in this case the point, which will then turn blue, must be tempered again. Be not too hasty in tempering; for sometimes a little whetting will bring it to a good condition, when it is but a little too hard.

To hold the graver, cut off that part of the handle which is upon the same line with the belly, or sharp edge of the graver; making that side flat, that it may be no obstruction.

Hold the handle in the hollow of your hand; and, extending your fore-finger towards the point, let it rest on the back of the graver, that you may guide it flat and parallel with the plate. Take care that your fingers do not interpose between the plate and the graver, for they will hinder you from carrying the graver level with the plate, and from cutting your strokes so clean as they ought to be.

To lay the design upon the plate, after you have polished it fine and smooth, heat it so that it will melt virgin-wax, with which rub it thinly and equally over, and let it cool. Then the design which you lay on, must be drawn on paper, with a black-lead pencil, and laid upon the plate, with its pencilled side upon the wax: then press it to, and with a burnisher go over every part of the design; and when you take off the paper, you will find every line which you drew with the black-lead pencil upon the waxed plate, as if it had been drawn: then, with a sharp-pointed tool, trace all your design through the wax upon the plate, and you may then take off the wax, and proceed to work.

Let the table, or board you work at, be firm and steady; upon which place your sand-bag with the plate upon it; and, holding the graver as above directed, proceed in the following manner.

For straight strokes, hold your plate firm upon the sand-bag with your left hand, moving your right hand forwards; leaning lighter where the stroke should be fine, and harder where you would have it broader.

For circular or crooked strokes, hold the graver stedfast; moving your hand, or the plate, as you see convenient.

Learn to carry your hand with such dexterity, that you may end your stroke as finely as you began it; and if you have occasion to make one part deeper or blacker than another, do it by degrees; and that you may do it with greater exactness, take care that your strokes be not too close, nor too wide.

In the course of your work, scrape off the roughness which arises, with your scraper; but be careful, in doing this, not to scratch the plate; and that you may see your work properly as you go on, rub it with the oil-rubber, and wipe the plates clean; which will take off the glare of the copper, and show what you have done to the best advantage.

Any mistakes or scratches in the plate may be rubbed out with the burnisher, and the part levelled with the scraper, polishing it again afterwards lightly with the burnisher, or charcoal.

Having thus attained the use of the graver, according to the foregoing rules, you will be able to finish any piece previously etched, by graving up the several parts to the colour required: beginning, as in the etching, with the fainter parts, and advancing gradually with the stronger, till the whole is completed. See ETCHING.

The dry point, or needle, (so called because not used till the ground is taken off the plate) is principally employed in the extremely light parts of water, sky, drapery, architecture, &c.

To prevent any obstruction from too great a degree of light, the use of a sash, made of transparent or fan paper, pasted on a frame, and placed sloping at a convenient distance between your work and the light, will preserve the sight; and when the sun shines, it cannot possibly be dispensed with.

Of mezzotinto engraving or scraping.—This art, which is of late date, is recommended by the amazing ease with which it is executed, especially by those who understand drawing.

Mezzotinto prints are those which have no patching, or strokes of the graver, but whose lights and shades are blended together, and appear like a drawing in Indian ink. They are different from aqua tinta; but as both resemble Indian ink, the difference is not easily described. Mezzotinto is applied to portraits and historical subjects, and aqua tinta is used only for landscape and architecture.

The tools necessary for mezzotinto scraping are the grounding-tool, burnishers, and scrapers.

To lay the mezzotinto ground, lay your plate, with a piece of flannel under it, upon your table; hold the grounding-tool in your hand perpendicularly; lean upon it moderately hard, continually rocking your hand in a right line from end to end, till you have wholly covered the plate in one direction: next cross the strokes from side to side, afterwards from corner to corner, working

the tool each time all over the plate, in every direction, almost like the points of a compass; taking all possible care not to let the tool cut (in one direction) twice in a place. This done, the plate will be full, or, in other words, all over rough alike; and would, if it was printed, appear completely black.

Having laid the ground, take the scrapings of black chalk, and with a piece of rag rub it over the plate; or you may smoke it with candles, as before directed for etching.

Now take your drawing, and having rubbed the back with red-chalk dust, mixed with flake-white, proceed to trace it on the plate.

To form the lights and shadows, take a blunt needle, and mark out the outlines only: then with a scraper scrape off the lights in every part of the plate, as clean and smooth as possible, in proportion to the strength of the lights in your drawing, taking care not to hurt your outlines.

The use of the burnisher is to soften or rub down the extreme light parts, after the scraper is done with; such as the tip of the nose, forehead, linen, &c. which might otherwise, when proved, appear rather misty than clear.

Another method used by mezzotinto-scrapers is, to etch the outlines of the original, as also the folds in drapery, making the breadth of the shadows by dots; which having bit to a proper depth with aqua fortis, they take off the ground used in etching, and having laid the mezzotinto-ground, proceed to scrape as above.

When your plate is ready for taking a proof, or impression, send it to the copper-plate printer, and get it proved. When the proof is dry, touch it with white chalk where it should be lighter, and with black chalk where it should be darker: and when the print is retouched, proceed as before for the lights; and for the shades use a small grounding-tool, as much as you judge necessary, to bring it to a proper colour; and when you have done as much as you think expedient, prove it again; and so proceed to prove and touch till it is entirely to your mind.

Engraving in aqua tinta.—Aqua tinta is a method of producing prints very much resembling drawings in Indian ink.

The principle of the process consists in corroding the copper with aqua fortis, in such a manner, that an impression from it has the appearance of a tint laid on the paper. This is effected by covering the copper with a powder, or some substance which takes a granulated orm, so as to prevent the squa fortis from acting where the particles adhere; and by this means cause it to corrode the copper partially, and in the interstices only. When these particles are extremely minute and near to each other, the impession from the plate appears to the naked eye exactly like a wash of Indian Ink; but when they are larger, the granulation is more distinct: and as this may be varied at pleasure, it is capable of being adapted with great success, to a variety of purposes and subjects.

This powder, or granulation, is called the aqua-tinta grain, and there are two general modes of producing it.

We shall first describe what is called the powder-grain, because it was the first that was used.

Having etched the outline on a copper-plate, prepared in the usual way by the coppersmith, (for which see the article Etching) some substance must be finely powdered and sifted, which will melt with heat, and when cold will adhere to the plate, and resist the action of aqua-fortis. The substances which have been used for this purpose, either separately or mixed, are asphaltum, Burgundy pitch, rosin, gum-copal, gum-mastich; and, in a greater or less degree, all the resins and gum-resins will answer the purpose. Common rosin has been most generally used, and answers tolerably well; though gum-copal makes a grain that resists the aqua fortis better.

The substance intended to be used for the grain, must now be distributed over the plate as equally as possible; and different methods of performing this essential part of the operation have been used by different engravers, and at different times.

The most usual way is, to tie up some of the powder in a piece of muslin, and strike it against a piece of stick, held at a considerable height above the plate; by this, the powder that issues falls gently, and settles equally over the plate. Every one must have observed how uniformly hair-powder settles upon the furniture after the operations of the hair-dresser. This may afford a hint towards the best mode of performing this part of the process. The powder must fall upon it from a considerable height, and there must be a sufficiently large cloud of the dust formed. The plate being covered equally over with the dust, or powder, the operator is next to proceed to fix it upon the plate, by heating it gently, so as to melt the particles. This may be effected by holding under the plate lighted pieces of brown paper rolled up, and moving them about till every part of the powder is melted; this will be known by its change of colour, which will turn brownish. It must now be suffered to cool, when it may be examined with a magnifier, and if the grains or particles appear to be uniformly distributed, it is ready for the next part of the process.

The design or drawing to be engraved must now be examined, and such parts of it as are perfectly white are to be remarked. Those corresponding parts of the plates must be covered, or stopped out as it is called, with turpentine-varnish, diluted with turpentine to a proper consistence to work freely with the pencil, and mixed with lamp-black to give it colour; for if transparent, the touches of the pencil would not be so distinctly seen. The margin of the plate must also be covered with varnish. When the stopping out is sufficiently dry, a border of wax must be raised round the plate, in the same manner as in etching, and the aqua fortis properly diluted with water poured on. This is called biting in, and is the part of the process which is most uncertain, and which requires the greatest degree of experience. When the aqua fortis has lain on so long that the plate, when printed, would produce the lightest tint in the drawing, it is poured off, and the plate washed with water and dried. When it is quite dry, the lightest tints in the drawing are stopped out, and the aqua fortis poured on as before, and the same process is repeated as often as there are tints to be produced in the plate.

Although many plates are etched entirely by this meth-

od of stopping out and biting in alternately, yet it may easily be conceived, that in general, it would be very difficult to stop round, and leave out all the finishing touches; as also the leaves of trees, and many other objects, which it would be impossible to execute with the necessary degree of freedom in this manner.

To overcome this difficulty, another very ingenious process has been invented, by which these touches are laid on the plate with the same ease and expedition as they are in a drawing in Indian ink. Fine washed whiting is mixed with a little treacle or sugar, and diluted with water in the pencil, so as to work freely; and this is laid on the plate covered with the aquatint ground, in the same manner and on the same parts as ink on the drawing. When this is dry, the whole plate is varnished over with a weak and thin varnish of turpentine, asphaltum, or mastich, and then suffered to dry, when the aqua fortis is poured on. The varnish will immediately break up in the parts where the treacle mixture was laid, and expose all those places to the action of the acid, while the rest of the plate remains secure. The effect of this will be, that all the touches or places where the treacle was used, will be bit in deeper than the rest, and will have all the precision and firmness of touches in Indian ink.

After the plate is completely bit in, the bordering-wax is taken off, by heating the plate a little with a lighted piece of paper; and it is then cleared from the ground and varnish by oil of turpentine, and wiped clean with a rag and a little fine whiting, when it is ready for the printer.

The principal disadvantages of this method of aquatinting are, that it is extremely difficult to produce the required degree of coarseness or fineness in the grain, and that plates so engraved do not print many impressions before they are worn out. It is therefore now very seldom used, though it is occasionally of service.

We next proceed to describe the second method of producing the aquatint ground, which is generally practised. Some resinous substance is dissolved in spirit of wine, as common resin, Burgundy pitch, or mastich, and this solution is poured all over the plate, which is then held in a slanting direction till the superfluous fluid drains off; and it is laid down to dry, which it does in a few minutes. If the plate is then examined with the magnifier, it will be found that the spirit, in evaporating, has left the resin in a granulated state; or rather, that the latter has cracked in every direction, still adhering firmly to the copper.

A grain is thus produced with the greatest ease, which is extremely regular and beautiful, and much superior for most purposes to that produced by the former method. After the grain is formed, every part of the process is conducted in the same manner as above described.

Having thus given a general idea of the art, we shall mention some particulars necessary to be attended to, in order to ensure success in the operation. The spirit of wine used for the solution, must be highly rectified, and of the best quality. What is sold in the shops, generally contains camphor, which would entirely spoil the grain. Resin, Burgundy pitch, and gum mastich, when dissolved in spirit of wine, produce grains of a different appearance and figure; and are sometimes used separately, and sometimes mixed in different proportions, according to the taste of the artist, some using one substance and some another. In order to produce a coarser or finer grain, it is necessary to use a greater or smaller quantity of resin; and to ascertain the proper proportions, several spare pieces of copper must be provided, on which the liquid may be poured, and the grain examined, before it is applied to the plate to be engraved. After the solution is made, it must stand still and undisturbed for a day or two, till all the impurities of the resin have settled to the bottom, and the fluid is quite pellucid. No other method of freeing it from those impurities has been found to answer; straining it through linen or muslin, only fills it with hairs, which are ruinous to the grain. The room in which the liquid is poured on the plate, must be perfectly still and free from dust; which, whenever it falls on the plate while wet, causes a white spot, which it is impossible to remove without laying the grain afresh. The plate must also be previously cleaned, with the greatest possible care, with a rag and whiting, as the smallest stain or particle of grease produces a streak or blemish in the grain. All these attentions are absolutely necessary to produce a tolerably regular grain; and, after every thing that can be done by the most experienced artists, still there is much uncertainty in the process. They are sometimes obliged to lay on the grains several times, before they procure one sufficiently regular. The same proportions of materials do not always produce the same effect, as it depends in some degree on their qualities; and it is even materially altered by the weather. These difficulties are not to be surmounted but by a great deal of experience; and those who are daily in the habit of practising the art, are frequently liable to the most unaccountable accidents. Indeed it is much to be lamented, that so elegant and useful a process should be so extremely delicate and uncertain.

It being necessary to hold the plate in a slanting direction, in order to drain off the superfluous fluid, there will naturally be a greater body of the liquid at the bottom than at the top of the plate. On this account, a grain laid in this way is always coarser at the side of the plate that was held lowermost. The most usual way is, to keep the coarsest side for the fore-ground, that being generally the part which has the deepest shadows. In large landscapes, sometimes various parts are laid with different grains, according to the nature of the subject.

The finer the grain is, the more nearly does the impression resemble Indian ink, and the fitter it is for imitating drawings: but very fine grains have several disadvantages; for they are apt to come off before the aqua fortis has lain on long enough to produce the desired depth; and as the plate is not corroded so deep, it sooner wears out in printing; whereas coarser grains are firmer, the acid goes deeper, and the plate will throw off a great many more impressions. The reason of all this is evident, when it is considered, that in the fine grains the particles are small and near each other, and consequently the aqua fortis, which acts laterally as well as downwards, soon undermines the particles, and causes them to come off. If left too long on the plate, the acid would eat away the grain entirely.

On these accounts, therefore, the moderately coarse

grains are more sought after, and answer better the purpose of the publisher, than the fine grains which were formerly in use.

Although there are considerable difficulties in laying properly the aquatint grain, yet the corroding of the copper, or bitting in, so as to produce exactly the tint required, is still more precarious and uncertain. All engravers allow that no positive rules can be laid down, by which the success of this process can be secured; nothing but a great deal of experience and attentive observation can enable the artist to do it with any degree of certainty.

There are some hints, however, which may be of considerable importance to the person who wishes to attain the practice of this art. It is evident, that the longer the acid remains on the copper, the deeper it bites, and consequently the darker will be the shade in the impression. It may be of some use, therefore, to have several bits of copper laid with aquatint grounds, of the same kind to be used in the plate, and to let the aqua fortis remain for different lengths of time on each; and then to examine the tints produced in one, two, three, four minutes, or longer. Observations of this kind, frequently repeated, and with different degrees of strength of the acid, will at length assist the judgment, in guessing at the tint which is produced in the plate. A magnifier is also useful to examine the grain, and to observe the depth to which it is bitten. It must be observed, that no proof of the plate can be obtained till the whole process is finished. If any part appears to have been bitten too dark, it must be burnished down with a steel burnisher; but this requires great delicacy and good management not to make the shade streaky; and as the beauty and durability of the grain are always somewhat injured by it, it should be avoided as much as possible.

Those parts which are not dark enough, must have a fresh grain laid over them, and be stopped round with varnish, and subjected again to the aqua fortis. This is called rebiting, and requires peculiar care and attention. The plate must be very well cleaned out with turpentine before the grain is laid on, which should be pretty coarse, otherwise it will not lie upon the heights only, as is necessary in order to produce the same grain. If the new grain is different from the former, it will not be so clear nor so firm, but rotten.

We have now given a general account of the process of engraving in aqua tinta, and we believe that no material circumstance has been omitted that can be communicated without seeing the operation: but after all it must be confessed, that no printed directions whatever can enable a person to practise it perfectly. Its success depends upon so many niceties, and attention to circumstances apparently trifling, that the person who attempts it must not be surprised if he does not succeed at first. It is a species of engraving simple and expeditious, if every thing goes on well; but it is very precarious, and the errors which are made are rectified with great difficulty.

It seems to be adapted chiefly for imitation of sketches, washed drawings, and slight subjects; but does not appear to be at all calculated to produce prints from finished pictures, as it is not susceptible of that accuracy in the balance of tints necessary for this purpose. Nor does it appear to be suitable for book-plates, as it does not print a sufficient number of impressions. It is therefore not to be put in competition with the other modes of engraving. If confined to those subjects for which it is calculated, it must be allowed to be extremely useful, as it is expeditious, and may be attained with much less trouble than any other mode of engraving. But even this circumstance is a source of mischief, as it occasions the production of a multitude of prints, that have no other effect than that of vitiating the public taste. See ETCHING.

Engraving on wood.—Engraving on wood is a process exactly the reverse to engraving on copper. In the latter, the strokes to be printed are sunk, or cut into the copper, and a rolling-press is used for printing it; but in engraving on wood, all the wood is cut away, except the lines to be printed, which are left standing up like types, and the mode of printing is the same as that used in letter-press.

The wood used for this purpose is box-wood, which is planed quite smooth. The design is then drawn upon the wood itself with black lead; and all the wood is cut away with gravers and other proper tools, except the lines that are drawn. Or sometimes the design is drawn upon paper, and pasted upon the wood, which is cut as before. The art is of considerable difficulty, and there are very few who practise it. It is, however, useful for books, as the printing of it is cheaper than that of copper-plates. It cannot be applied equally well to all the purposes to which copper-plate engraving is applicable.

In *engraving on precious stones*, they use either the diamond, or emery. The diamond, which is the hardest of all stones, is only cut by itself, or with its own matter. The first thing to be done in this branch of engraving, is to cement two rough diamonds to the ends of two sticks large enough to hold them steady in the hand, and to rub or grind them against each other till they are brought to the desired form. The dust, or powder, that is rubbed off, serves afterwards to polish them, which is performed with a kind of mill that turns a wheel of soft iron. The diamond is fixed in a brass dish, and thus applied to the wheel, is covered with diamond-dust, mixed up with oil of olives; and when the diamond is to be cut facet-wise, they apply first one face, then another, to the wheel. Rubies, sapphires, and topazes, are cut and formed the same way on a copper wheel, and polished with tripoli diluted in water. As to agates, amethysts, emeralds, hyacinths, granites, rubies, and others of the softer stones, they are cut on a leaden wheel, moistened with emery and water, and polished with tripoli, on a pewter wheel. Lapis-lazuli, opal, &c. are polished on a wooden wheel. To fashion and engrave vases of agate, crystal, lapis-lazuli, or the like, they make use of a kind of lathe, like that used by pewterers to hold the vessels, which are to be wrought with proper tools: that of the engraver generally holds the tools, which are turned by a wheel; and the vessel is held to them to be cut and engraved, either in relievo or otherwise; the tools being moistened, from time to time, with diamond-dust and oil, or at least emery and water. To engrave figures or devices on any of these stones, when polished, such as medals, seals, &c. they use a little iron wheel, the ends of

whose axis are received within two pieces of iron, placed upright, as in the turner's lathe; and to be brought closer, or set further apart, at pleasure: at one end of the axis are fitted the proper tools, being kept tight by a screw. Lastly, the wheel is turned by the foot, and the stone applied by the hand to the tool, and is shifted and conducted as occasion requires.

The tools are generally of iron, and sometimes of brass: their form is various; but it generally bears some resemblance to chisels, gouges, &c. Some have small round heads, like buttons; others like ferules, to take the pieces out; and others flat, &c. When the stone has been engraved, it is polished on wheels of hair-brushes and tripoli.

Engraving on steel is chiefly employed in cutting seals, punches, matrices, and dyes proper for striking coins, medals, and counters. The method of engraving with the instruments, &c. is the same for coins as for medals and counters. All the difference consists in their greater or less relievo, the relievo of coins being much less considerable than that of medals, and that of counters still less than that of coins.

Engravers in steel commonly begin with punches, which are in relievo, and serve for making the creux, or cavities, of the matrices and dyes; though sometimes they begin with the creux, or hollowness, but then it is only when the intended work is to be cut very shallow. The first thing done, is that of designing the figures; the next is the moulding them in wax, of the size and depth they are to lie, and from this wax the punch is engraved. When the punch is finished, they give it a very high temper, that it may the better bear the blows of the hammer with which it is struck, to give the impression to the matrix.

The steel is made hot to soften it, that it may the more readily take the impression of the punch; and after striking the punch on it, in this state, they proceed to touch up or finish the strokes and lines, where, by reason of their fineness, or the too great relievo, they are any thing defective, with steel gravers of different kinds, chisels, flatters, &c. being the principal instruments used in graving on steel.

The figure being thus finished, they proceed to engrave the rest of the medal, as the mouldings of the border, the engrailed ring, letters, &c. with little steel punches, well tempered, and very sharp.

ENMANCHE', in heraldry, is when lines are drawn from the centre of the upper edge of the chief to the sides, to about half the breadth of the chief; signifying sleeved, or resembling a sleeve, from the French manche.

ENNEANDRIA, in botany, the ninth class of plants with hermaphrodite flowers, and nine stamina or male parts in each. See Botany. To this class belong the laurus, rheum, spondias, butomus, &c.

ENSIFORM, in general, something resembling a sword, ensis: thus we find mention of ensiform leaves, ensiform cartilage, &c.

ENSIGN, in the military art, a banner under which the soldiers are ranged according to the different companies or parties they belong to.

Ensign is also the officer that carries the colours, being the lowest commissioned officer in a company of foot, subordinate to the captain and lieutenant.

ENTABLATURE, or *entablement*, in architecture, is that part of an order of a column which is over the capital, and comprehends the architrave, frieze, and corniche.

Entablature, in masonry, is used sometimes to denote the last row of stones on the top of the wall of a building, on which the timber and covering rest. This is often made to project beyond the naked part of the wall, to carry off the rain.

ENTAIL, in law, is a fee-estate entailed; that is, abridged and limited to certain conditions prescribed by the donor or grantor. See Estate.

ENTE', in heraldry, a method of marshalling, more frequent abroad than with us, and signifying grafted or engrafted.

ENTEROCELE. See Surgery.

ENTERPLEADER, in law, signifies the discussing or trial of a point, incidentally falling out, before the principal cause can be determined.

ENTHYMENE, among logicians, denotes a sylogism, perfect in the mind, but imperfect in the expression, because one of the propositions is suppressed, as being easily supplied by the understanding of those with whom we discourse: *e.g.* "In every right-lined triangle the three angles are just equal to two right ones; therefore, those of an isosceles are so:" where the proposition, "every isosceles is a right-lined triangle," is omitted, as being sufficiently known.

ENTOMOLOGY, that part of the science of zoology which treats exclusively of insects.

Some natural historians consider this class of animals the most imperfect of any, while others prefer them to the larger animals. One mark of their imperfections is said to be, that many of them can live a long time, though deprived of those organs which are necessary to life in the higher ranks of nature. Many of them are furnished with lungs and a heart, like the nobler animals; yet the caterpillar continues to live, though its heart and lungs, which is often the case, are entirely eaten away. It is not however from their conformation alone that insects are inferior to other animals, but from instincts also. It is true, that the ant and bee present us with striking instances of assiduity; yet even these are inferior in the marks of sagacity displayed by the larger animals. A bee taken from the swarm is totally helpless and inactive, incapable of giving the smallest variations to its instincts. It has but one single method of operating: and if put from that, it can turn to no other. In the pursuits of the hound, there is something like choice; but in the labours of the bee, the whole appears like necessity and compulsion. All other animals are capable of some degree of education; their instincts may be suppressed or altered; the dog may be taught to fetch and carry, the bird to whistle a tune, and the serpent to dance: but the insect has only one invariable method of operating; no arts can turn it from its instincts; and indeed its life is too short for instruction, as a single season often terminates its existence. Their amazing number is also an imperfection. It is a rule that obtains through all nature, that the nobler animals are slowly produced, and that nature acts with a kind of dignified economy; but the meaner births are lavished in profusion, and thousands are brought forth merely to supply the necessities of the more fa-

vourite part of the creation. Of all productions in nature, insects are by far the most numerous. The vegetables which cover the surface of the earth bear no proportion to the multitudes of insects; and though, at first sight, herbs of the field seem to be the parts of organized nature produced in the greatest abundance, yet, upon more minute inspection, we find every plant supporting a mixture of scarcely perceptible creatures, that fill up the compass of youth, vigour, and age, in the space of a few days existence. In Lapland and some parts of America, the insects are so numerous, that if a candle is lighted they swarm about it in such multitudes, that it is instantly extinguished by them; and in those parts of the world, the miserable inhabitants are forced to smear their bodies and faces with tar, or some other unctuous composition, to protect them from the stings of their minute opponents.

Swammerdam however argues for the perfection of insects in the following manner. "After an attentive examination (says he) of the nature and anatomy of the smallest as well as the largest animals, I cannot help allowing the least an equal, or perhaps a superior, degree of dignity. If, while we dissect with care the larger animals, we are filled with wonder at the elegant disposition of their parts, to what a height is our astonishment raised, when we discover all these parts arranged, in the least, in the same regular manner! Notwithstanding the smallness of ants, nothing hinders our preferring them to the largest animals, if we consider either their unwearied diligence, their wonderful powers, or their inimitable propensity to labour. Their amazing love to their young is still more unparalleled among the larger classes. They not only daily carry them to such places as may afford them food, but if by accident they are killed, and even cut into pieces, they will with the utmost tenderness carry them away piece-meal in their arms. Who can show such an example among the larger animals which are dignified with the title of perfect? Who can find an instance in any other creature that can come in competition with this?"

On this dispute it is only necessary to observe, that the wisdom of the Creator is so conspicuous in all his works, and such surprising art is discovered in the mechanism of the body of every creature, that it is very difficult, if not impossible, to say where it is most, and where it is least, to be perceived.

Those who are desirous of attaining a systematic knowledge of insects, ought primarily to be solicitous about acquiring the terms made use of in the science, that so they may be able rightly to denominate every part of an insect. The student is first to know what an insect is, lest he mistake the hippocampi, and other amphibious animals, for them, as was formerly done: or confound them with the vermes, which Linnæus first distinguished from insects, and which differ as essentially from them as the class mammalia do from birds. Every insect is furnished with a head, antennæ, and feet, of all which the vermes are destitute. All insects have six or more feet; they respire through pores placed on the sides of their bodies, and which are termed spiracula: their skin is extremely hard, and serves them instead of bones, of which they have internally none. From this definition, the acus marina is evidently no insect. But the antennæ placed on the fore-part of the head constitute the principal distinction. These are jointed and moveable in every part, in which they differ from the horns of other animals: they are organs conveying some kind of sense; but we have no more idea of what this kind of sense is, than a man has, who, without eyes, attempts to determine the particular action of the rays of light on the retina of the eye, or to explain the changes which thence take place in the human mind. That they are the organs of some kind of sense, is apparent from their perpetually moving them forward: yet the hard crust with which they are invested, and their shortness in flies and other insects, would induce one to believe them not to be the organs of touch: Mr. Barbut supposes them to constitute or to contain the organs of hearing, because they are tubular, and filled with air and some kind of humour, as appears from the antennæ of butterflies immersed in water. To come now to the terms of the art. A knowledge of the external parts of the body is first to be established; which, after the method of anatomists, we may divide into head, trunk, abdomen, and extremities.

Of the external parts of the body.

I. Caput, the head. It is asserted in the Fundamental Entomologiæ, that this part in insects is without brain. The difference between the brain and the spinal marrow consists in the former being a medullary part organized. We do not deny the existence of a medullary thread in the heads of insects, but we never could discover it to be organized; hence the hippobosca equina, or horsefly, will live, run, nay even copulate, after being deprived of its head: to say nothing of many others which are capable of living a long while under the same circumstances.

Insects not being apparently furnished with ears, they have been apprehended incapable of hearing; as we can no more conceive that sense to exist without ears, than vision without eyes. That they are nevertheless susceptible of any shrill or loud noise, as well as fishes, is indisputable; but it has been supposed to be in a manner different from that of hearing. Mr. Barbut, however, supposes them to possess this sense in a very distinct manner. Many insects, he observes, are well known to be endowed with the power of uttering sounds, such as large beetles, the bee, wasp, common fly, gnat, &c. The sphinx atropos squeaks, when hurt, nearly as loud as a mouse. Now, if insects are endowed with the power of uttering sounds, it certainly must be for some purpose. As they vary their cry occasionally, it must be certainly designed either to give notice of pleasure or pain, or some affection in the creature who possesses it. "The knowledge of their sounds (says our author) is undoubtedly confined to their tribe, and is a language intelligible to them only; saving when violence obliges the animal to exert the voice of nature in distress craving compassion; then all the animals understand the doleful cry. For instance: attack a bee or wasp near the hive or a few of them: the consequence of that assault will be, the animal or animals, by a different tone of voice, will express his or their disapprobation or pain; that sound is known to the hive to be plaintive, and that their brother or brethren require their assistance; and the offending

party seldom escapes with impunity. Now, if they had not the sense of hearing, they could not have known the danger their brother or brethren were in by the alteration of their tone."

A still more decisive proof occurred to his observation in a large spider in St. James's park. This creature had made a very large web on a wooden railing; and was at the time of observation, on one of the rails at a considerable distance from the place where a large fly had entangled itself. Nevertheless, the moment the fly was entangled, the spider became sensible of it; though from the situation of the rail, he could not possibly have seen it. In this, however, Mr. Barbut might possibly be deceived; because the spider was perhaps alarmed by the tremulous motion of the threads, occasioned by the fluttering of the fly; which he might well know how to distinguish from their vibration by the wind. The organ of hearing, in our author's opinion, is situated in the antennæ; both from their situation in the part of the head most favourable to such organs, and their inward structure being moveable; the ears of the most inferior animals being so. He has never considered the antennæ as either offensive or defensive, but has observed them to have been endowed with an exquisite sense of feeling; that the animal appeared to be in agony when its antennæ were pinched; and that it takes care to avoid the touching any hard substance with them roughly. "This tenderness in the organ of hearing (says he) is common to all animals; and insects seem to be particularly tender in these parts, by quickly withdrawing them from the touch."

This writer further observes, that the antennæ of all insects are composed of joints varying in size, form, and number. Those who are chiefly confined to live under water, have their antennæ in general shorter than those who live on land. Some who roam at large in the air, have them long and slender. They are all hollow, and are rendered flexible by the joints, which are very visible in the horns of the crab and lobster. This hollowness, in our author's opinion, is to receive the sound communicated to the extremities of the antennæ by the repercussion of the air affected by any noise; and conveys it, by means of the joints, from one to another, till it arrives in that lessened degree of tone best suited to the timid nature of the animal. In this circumstance there may be many variations in point of perfection in those organs; the strength, utility, and degree of power in receiving sound, being proportioned to the necessities of the animals, different in their nature and requisites. In most animals, the entrance to the auricular organ is patulous: but in this case the animal would suffer great inconvenience from such an organization, as the orifice would be subject to impediments from dirt, &c.

Most naturalists are in doubt whether insects have the sense of smell, no organs being found in them adapted to that purpose: and although it was evident they had a perception of agreeable and fetid effluvia, it was thought to be in a manner altogether unknown to us. Mr. Barbut is of opinion that the organs of smell reside in the palpi or feelers. Many insects have four, and some six, two of which are in general chiliform, in order to assist the insect in conveying its food to its mouth. It may be likewise observed, that the palpi are in a continual motion; the animal thrusting them into every kind of putrid or other matter, as a hog would his nose, smelling and searching after food. Insects which apparently do not possess palpi or spiral tongues, have undoubtedly some organs concealed within the mouth, analogous to them in function and utility; the fleshy proboscis of the fly is thurst into every substance in which the animal expects to find food; and when it is extended, nearly in the middle are situated, in our author's opinion, two upright palpi, which, no doubt, perform in their turn some office, and perhaps that of smell.

Many insects are without the tongue, nor do they make any sound with their mouth; but for this purpose some use their feet, others their wings, and others some elastic instrument with which they are naturally furnished.

Eyes. Most insects have two eyes; but the gyrinius has four, the scorpion six, the spider eight, and the scolopendra three. They have no eyebrows, but the external tunic of the eye is hard and transparent like a watch-glass; their eyes have no external motion, unless it be in the crab. They consist for the most part of one lens only; but in those of the butterfly, diptera, and many of the beetles, they are more numerous. Pugett discovered 17,325 lenses in the cornea of a butterfly, and Lieuwenhoek 800 in that of a fly.

Antennæ. The number of these is generally two (unless four are allowed to some crabs), and are placed on the fore part of head: they are peculiar to insects; and are plainly distinguishable from the tentacula of the vermes, in being crustaceous: and from the palpi of insects, which are more numerous, placed near the mouth, and are sometimes wanting. As the antennæ are of great moment in distinguishing the various kinds of insects, we shall enumerate and explain the several different forms of them.

Setaceæ, are those which grow gradually tapering towards the extremity.

Filiformes, such as are of the same thickness throughout.

Moniliformes, are filiformes, like the preceding, but consist of a series of round knobs, like a necklace of beads.

Clavatæ, such as gradually increase in size toward the extremity.

Capitatæ are clavatæ, but have the extremity somewhat round.

Fissiles are capitatæ; but have the capitulum, or knob, divided longitudinally into three or four parts, or laminæ, as in scarabæi.

Perfoliatæ are also capitatæ; but have the capitulum horizontally divided, as in the dermestes.

Pectinatæ, so called from their similitude to a comb, though they more properly resemble a feather, as in the moths and elateres: this is most obvious in the male.

Alistatæ, such as have a lateral hair, which is either naked, or furnished with lesser hairs, as in the fly.

Breviores, those which are shorter than the body.

Longiores, those which are longer than the body.

Mediocres, those which are of the same length with the body; all three of which varieties are distinguishable in the cerambyces.

Palpi, or feelers, resemble filiform, articulated, movea-

ble antennæ. They are most commonly four in number, sometimes six; they are sufficiently distinguished from antennæ, in being naked, short, and always placed at the mouth.

Os, the mouth, is generally placed in the anterior part of the head, extending somewhat downwards. In some insects, it is placed under the breast; as in the chermes, coccus, cancer (crab), and circulio.

Rostrum or proboscis, is a mouth drawn out to a rigid point: in many of the hemiptera class it is bent downward towards the breast and belly, as in the cicada, nepa, notonecta, cimex (bug), aphis, and remarkably so in some curculiones.

Maxillæ, the jaws, are two in number, sometimes four, and at other times more; they are placed horizontally; the inner edge of some insects is serrated, or furnished with little teeth.

Lingua, the tongue, in some insects is taper and spiral, as in the butterfly; in others it is fleshy, resembling a proboscis, and tubular, as in the fly.

Labium superius, the upper lip, is situated above the jaws; as in the scarabæus and gryllus.

Stemmata, or crown, are three smooth hemispheric dots, placed generally on the top of the head; as in most of the hemenoptera, and others.

II. Truncus, the trunk, is that part which comprehends the breast or thorax: it is situated between the head and abdomen; and has the legs inserted into it, that its parts may be distinctly determined. It is divided into thorax, scutellum, and sternum.

Thorax, the chest, is the back part of the breast; and is very various in its shape. It is called dentatus, when its sides are armed with points.

Spinosus, when its back is furnished with them, as in the cerambyx; and marginatus, when its margin is laterally dilated, as in the silpha and cassida.

Scutellum, or escutcheon, is the posterior part of the thorax; it is frequently triangular, and appears to be divided from the thorax by an intervening suture, as in most of the coleoptera.

The sternum, or breast-bone, is situated on the inferior part of the thorax; it is pointed behind in the elateres, and bifid in some of the dytisci.

III. The abdomen is in most insects distinct from the thorax; it is the posterior part of the body of the insect; and is composed of a number of annular segments which serve occasionally to lengthen or shorten it, and to contain the organs of chylification, &c.

Spiracula, are little holes or pores, placed singly on each side of every segment of the abdomen: through these the insect breathes; and if oil is applied so as to stop them up, it proves fatal to most of them.

Tergum, the back, is the superior part of the abdomen.

Venter, the belly, is the inferior part.

Anus, is the posterior part of the abdomen, perforated for the evacuation of the excrement. This part also frequently contains the organs of generation.

IV. Artus, the limbs, or extremities, are the various instruments of motion.

Pedes, the legs, are generally six. There is an exception to this, however, in the class apiera, many of which have eight: as acari (mites), phalangii, most of the aranei (spiders), scorpiones (scorpions), and cancri (crabs). The oniscus has 14, and the iuli and scolopendri still more.

The first joint of the leg, which is generally thickest, is called femur: the second, which is generally of the same size throughout, tibia: the third, which is jointed, is distinguished by the name of tarsius; and the last, which in most insects is double, by that of unguis. The legs of insects, in general, are named from the various motions they produce: as

Cursorii, from that of running, which are most numerous.

Saltaorii, from that of leaping.

Natatorii, from that of swimming, &c. In the saltatorii, the thighs are remarkably large, by which means they are able to leap to a considerable distance, as in the gryllus, grass-hopper, &c. In those of the natatorii, the feet are flat, and edged with hairs, which answer the same purpose as oars in assisting them to swim, as in the dytiscus.

Mutici, are such feet as have no claws.

Chelæ, or claws, are the fore-feet enlarged towards their extremities, each of which is furnished with two lesser claws, which act like a thumb and finger; as in the crab.

Alæ, wings, the instruments which enable the insect to fly. These are membranous and undivided, except in the instance of the phalænæ alucitæ, in which they are in part divided. Most insects have four; the diptera class, and the coccus, however, have only two.

The wing is divided into its superior and inferior surfaces: its anterior part in a butterfly, is that towards the anterior margin, or next to the head; its posterior part, that towards the anus; its exterior part, that towards the outer edge; and the interior, that next the abdomen.

They are called plicatiles, when they are folded at the time the insect is at rest, as in the wasp: opposite to these are the planæ, which are incapable of being folded.

Erectæ, such as have their superior surfaces brought in contact when the insect is at rest; as in the ephemera, puella and virgo, and papiliones (butterflies).

Patentes, which remain horizontally extended when the insect is at rest; as in the phalænæ geometræ, and most of the libellulæ.

Incumbentes, such as cover horizontally the superior part of the abdomen when the insect is at rest.

Deflexæ, are incumbents, but not horizontally, the outer edges declining towards the sides.

Reverse, are deflexæ, with this addition, that the edge of the inferior wings projects from under the anterior part of the superior ones.

Dentate, in which the edge is serrated, or scalloped.

Caudatæ, in which one or more projections in the hinder wings are extended into processes.

Reticulatæ, when the vessel of the wings put on the appearance of net-work, as in the hemerobius perla: the two anterior wings generally become superior, and the posterior ones inferior, in moths, when their wings are closed; but the anterior wings are called primary, and the inferior ones secondary, in butterflies, as they can-

not with propriety be called inferior when the wings are erect.

Colores, the colours; these are various and apparent; but according to their several shapes, they take the different names of punctæ, dots; and maculæ, spots.

Fasciæ, bands, which frequently run across and sometimes surround the edge of the wings.

Striæ, streaks, which are very slender fasciæ, and lineæ, lines, which are longitudinally extended.

Ocellus, is a round spot containing a lesser spot of a different colour in its centre.

Stigma, another term lately introduced by Linnæus, signifies the spot, or anastomis, in the middle of the wing near the anterior margin; it is conspicuous in most of the hymenoptera and neuroptera, and even in the coleoptera. The single or double kidney-shaped spot, situated in the same part of the anterior wings, and frequently occurring in the phalænæ paganæ, is distinguished likewise by the name of stigma.

Elytra (in the singular number elytron). The upper wings, or case, which are of a hard substance, in some degree resembling leather, and which in most insects are of a very hard texture, but in others flexible, are called elytra: their superior surface is generally convex, their inferior concave. When the insect flies, they are extended; and shut when it rests, closing together, and forming a longitudinal suture down the middle of the back, as in the coleoptera. They are of various shapes:

Abbreviata, when shorter than the abdomen.

Truncata, when shorter than the abdomen, and terminating in a transverse line.

Fastigata, when of equal or greater length than the abdomen, and terminating in a transverse line.

Serrata, when the exterior margin towards the apex is notched or serrated, as in some of the buprestes.

Spinosa, when the surface is covered with sharp points or prickles.

Scabra, when their surface is so uneven as to grate against the fingers.

Striata, when marked with slender longitudinal furrows.

Porcata, when with elevated longitudinal sulci or ridges.

Sulcata, when the ridges are concave.

Hemelytra, when the superior wings are of a middle substance between leather and membrane; either totally so, as in the grylli; or partially so, as in the cimices, nepæ, and notonectæ: these are commonly distinguished by the name hemiptera.

Halteres, poisers (a term also introduced by Linnæus), are little heads placed on a stalk or peduncle, most frequently under a little arched scale. They are found only in the class diptera, and appear to be nothing more than the rudiments of the hinder wings.

Cauda, the tail, in most insects is,

Simplex, simple, capable of being extended, and again drawn back at pleasure. In the crab and scorpion, however, it is

Elongata, elongated or lengthened.

Setacea, brittle shaped, or taper; as in the raphidea.

Triseta, consisting of three bristles; as in the ephemera.

Furcata, being forked, as in the podura.

Forcipata, resembling a pair of forceps; as in the forsicula.

Foliosa, resembling a leaf; as in the blatta, grylli, and some species of cancri.

Telifera, such as are armed with a dart or sting; as in the scorpion or panorpa.

Aculeus, the sting, an instrument with which they wound, and at the same time instil a poison: with such the bee, wasp, scorpion, &c. are furnished.

Explanation of the figures that accompany this article.

Plate LIV.

Fig. 62. Antennæ pectinatæ, or feathered; as in the phalænæ, moths.

63. ——— perfoliatæ, or perfoliated; as in the dermestes and dytiscus.

64. ——— fissiles, or fissile, divided into laminæ at the extremity; as in the scarabæi, beetles.

65. ——— clavatæ, or club-shaped; as in the papilio, butterfly.

66. Moniliformes, like a necklace of beads; as in the chrysomela.

67. ——— setaceæ, setaceous, or bristle-shaped; as in many of the phalænæ.

68. ——— aristatæ, furnished with a lateral hair; as in the fly.

69 and 70. *a*, caput, the head. *b*, palpi, or feelers. *c*, antennæ, or horns. *d*, oculi, the eyes. *e*, thorax. *f*, scutellum, or escutcheon. *g*, pectus, or breast. *h*, sternum, or breast-bone. *i*, abdomen, and its segments. *k*, anus. *l*, elytra, or shells. *m*, membranous wings. *n*, pedes, or feet, which are natatorii.

71. *o*, femur, or thigh. *p*, tibia, or leg. *q*, tarsus, or foot. *r*, unguis, or claw.

72. *a*, the anterior part of the wing. *b*, the posterior part. *c*, the exterior part. *d*, the interior part. *e*, the margin. *f*, the disk, or middle. *g*, oculus, or eye.

73, 74, 75, and 76. represent the insect in its egg, caterpillar, pupa, and perfect state.

Of the sexes of insects.

In insects the same difference exists as in other animals, and they even appear more disposed to increase their species than other animals; many of them, when become perfect, seeming to be created for no other purpose but to propagate their species. Thus the silkworm, when it arrives at its perfect or moth state, is incapable of eating, and can hardly fly: it endeavours only to propagate its species; after which the male immediately dies, and, as soon as she deposits her eggs, the female also expires.

The males and females of many insects are with difficulty distinguished; whilst in some they differ so widely, that an unskilful person might easily take the male and female of the same insect for different species: as for instance, in the phalæna humuli, piniari, russula: each sex of which differs in colour. This dissimilarity is still more apparent in some insects, in which the male has wings and the female none; as in the coccus, lampyris, phalæna antiqua, brumata, lichenella. And as most insects remain a long while in copulation, as we may see in the tipula and silkworm, the winged males fly with the wingless females, and carry them about from one place to another; as in the phalæna antiqua. It is, however, no certain rule, that when one insect of the same

species is found to have wings, and the other to be without, the former must necessarily be the male and the latter the female. The aphides, for instance, are an exception; and besides these, individuals of both sexes, and of the same species, are found without wings, as the carabi majores, tenebriones, meloes, cimices. The gryllus pedestris is likewise destitute of wings; and might have passed for a gryllus in its pupa state, had it not been seen in copulation; for it is well known that no insect can propagate its species till it arrives at its last or perfect state.

"Pleraque insectorum genitalia sua intra anum habent abscondita, et penes solitarios, sed nonnulla penem habent bifidum: cancri autem et aranei geminos, quemadmodum nonnulla amphibia, et quod mirandum in loco alieno, ut cancer, sub basi caudæ. *Araneus mas* palpos habet clavatos, qui penes sunt, juxta os utrinque unicum, quæ clavæ sexum nec speciem distinguunt; et fœmina vulvas suas habet in abdomine juxta pectus. Huic vero si unquam vere dixeris, *Res plena timoris amor:* si enim procus in auspicato accesserit, fœmina ipsum devorat; quod etiam sit, si non statim se retraxerit. Libellula fœmina genitale suum sub apice geret caudæ, et mas sub pectore; adeo ut cum mas collum fœminæ forcipe caudæ arripit, illa candam sub pectore ejus adplicet; sicque peculiari ratione connexæ volitent."

Besides those of male and female, a third sex exists in some insects which we call neuter: as these have not the distinguishing parts of either sex, they may be considered as eunuchs, or infertile. We know of no instance of this kind in any other class of animals, nor in vegetables, except in the class syngenesia, and in the opulus. This kind of sex is only found among those insects which form themselves into societies, as bees, wasps, and ants: and here these kind of eunuchs are real slaves, as on them lies the whole business of the economy; while those of the other sex are idle, only employing themselves in the increase of the family. See Apis. Among ants, the neuters form a hill in the shape of a cone, that the water may run off it, and place those which are in the pupa state on that side of it which is least exposed to the heat of the sun. At a considerable distance from these are found the habitations of the males and females, to whom the most ready obedience is yielded by the neuters, till a new offspring succeeds, and then they oblige them to quit their habitations. But those ants which live entirely under ground provide better for themselves in this respect; for a little before their nuptials they quit their habitation of their own accord, and, after swarming in the manner of bees, copulate in the air; and each retiring to some new habitation founds a new race.

No hermaphrodites have as yet been discovered among insects. There is something very singular, however, in the propagation of the aphides. A female aphis once impregnated can produce young, which will continue to produce others without any fresh impregnation, even to the tenth progeny; afterwards a new impregnation must take place.

The male insects, like male hawks, are always smaller than the females.

In the propagation of their species they are remarkably careful; so that it is with the greatest difficulty the flies are kept from depositing their egss on fresh meat, the cabbage-butterfly from laying them on cabbage, and other insects from depositing them on the several places peculiar to each. The scarabæus pilularis and carnifex are deserving of our attention, as they afford a mutual assistance to each other: for when the female has laid her eggs in a little ball of dung, the males with their feet, which are axiform, assist the female to roll it to some suitable place; as Aristotle and Pliny formerly, and Loefling has since remarked.

A fact not a little wonderful is, that in the coccus and oniscus the female has no sooner brought forth her young than she is devoured by it; and that the sphex should be able so readily to kill the caterpillar of a moth, then bury it in the earth, and there deposit her eggs in it. Nor can we without admiration behold the same species of aphis, which was viviparous in the summer, become oviparous in the autumn.

Almost innumerable examples might be brought of the singularities in the eggs of insects: we shall, however, only mention those of the hemerobius, which are deposited on a footstalk; those of the phalæna neustria, which are placed regularly in a ring round the branch of some tree; and the compound eggs of the blatta, or cockroach.

Of the metamorphoses of insects.

Except those of the aptera class, there are no insects but what are continually undergoing some transformation. They change first from the (ovum) egg, into the (larva) caterpillar, or maggot; then into the (pupa) chrysalis; and, lastly, into the (imago) fly, or perfect state. During each of those changes their appearance differs most essentially. The insect, as soon as it came out of the egg, was by former entomologists called eruca; b u as this is synonymous with the botanic name sisymbrium, it was changed by Linnæus for the term

Larva; a name expressive of the insect's being, in this state, as it were masked, having its true appearance concealed. Under this mask or skin the entire insect, such as it afterwards appears when perfect, lies concealed, enveloped only in its tender wings, and putting on a soft and pulpy appearance; insomuch that Swammerdam was able to demonstrate the butterfly with its wings to exist in a catterpillar, though it bore but a faint resemblance to its future perfection. The insect, therefore, in this state, undergoes no other alteration but the change of its skin. The larvæ are, for the most part, larger than the insect when perfect, and are very voracious. The caterpillar of the cabbage-butterfly eats double what it would seem to require from its size; its growth, however, is not adequate to its voracity.

Pupa. The insect in this state was formerly called chrysalis, or aurelia; but as the appearance of gilding is confined to a few butterflies only, the term of pupa has been adopted in its stead; because the lepidoptera, especially, resemble an infant in swaddling-cloths; and in this state none, except those of the hemiptera class, take any nourishment.

Imago is the third state. This name is given by Linnæus to the third change, in which the insect appears in its proper shape and colours; and as it undergoes no more transformations, it is called perfect. In this state it flies, is capable of propagating its species, and receives its true antennæ; which before, in most insects, were scarcely apparent.

As the shape of the pupa is different in different clas-

ses of insects, it assumes different names; thus it is called

Coarctata, when it is round, and as it were turned, without the least resemblance to the structure of the insect; as in the diptera.

Obtecta, when it consists as it were of two parts, one of which surrounds the head and thorax, and the other the abdomen.

Incompleta, when they have wings and feet, but are not capable of moving them: as in most of the hymenoptera.

Semi-completa, in which they walk or run, but have only the rudiments of wings.

Completa, in which they immediately obtain the perfect form of the insect, without undergoing any more change: as in those of the aptera class, except only the flea. The bed-bug also belongs to this class.

The spider undergoes frequent transformations, though only in the colour of its skin. The crustaceous insects, as crabs, lobsters, &c. yearly cast their shells, or their growth would otherwise be impeded. The scolopendri, when young, have fewer feet than when they are full-grown. All insects, as soon as they undergo the third change, are arrived at their full growth; nor do we find any difference in the size of the same species of insect in the same countries, unless, during its caterpillar state, it has not had a sufficiency of proper food.

Of the classification of insects.

The insect tribe being endowed with the various powers of creeping, flying, and swimming, there is scarcely any place, however remote and obscure, in which they are not to be found. The great confusion which appeared to the ancients to arise from their number, made them never dream of reducing them to any system. Swammerdam, that indefatigable inquirer into nature, observed, that their metamorphoses were divided by nature into several states or orders. Their external appearance also carried with it some mark of distinction: so that entomologists called all those of the coleoptera class scarabæi (beetles); those of the lepidoptera papiliones; and those of the gymnoptera class that had two wings only, muscæ (flies); those of the same class that had four wings, were called apes (bees). No farther progress was made in the systematic part of this science till the time of Linnæus. He was the first that undertook to determine the genera, and assign them their proper characters, in the Systema Naturæ; and thus reduced this science to a systematic form. This system, in subsequent editions, was considerably enriched and amended by him, insomuch that the science of insects now shines forth in its full lustre. He it was who first instituted natural orders, and reduced them into genera by expressive names; determined an infinite number of species in the Funa Succicæ and Museum Reginæ; collected with incredible pains the synonymous names of the various authors who had written on them; and, lastly, added their descriptions, and the places in which they were to be found: so that the system of this illlustrious author will lead any person, without the assistance of a master, for the most part, easily to ascertain the name of any insect he may meet with. Before his time scarcely any more than 200 insects were known; whereas, in the last edition of his system, he has determined the names of nearly 3000 distinct species; though this is not the sixth part of the number that is now known.

Orders.—The class of insects is divided by Linnæus into seven orders. 1. The coleoptera (from κωλεος a sheath, and πτερον a wing), are such insects as have crustaceous elytra or shells, which shut together, and form a longitudinal suture down the back of the insect; as the beetle (buprestis ignita), fig. 77. 2. Hemiptera (from ημισυ half, and πτερον a wing), have their upper wings usually half crustaceous and half membranaceous, not divided by a longitudinal suture, but incumbent on each other; as the cimex, fig. 78. 3. Lepidoptera (from λεπις a scale, and πτερον a wing), are insects having four wings, covered with fine scales in the form of powder or meal; as in the butterfly (papilio antiopa), fig. 79. 4. Neuroptera (from νευρον a nerve, and πτερον a wing), have four membranous transparent naked wings, generally like network; as in the panorpa coa, fig. 80. 5. Hymenoptera (from υμην a membrane, and πτερον a wing), are insects with four membranous wings; tail furnished with a sting, as in the tenthredo, fig. 81. 6. Diptera (from δυω two, and πτερον a wing), are such as have only two wings and poisers; as in the fly (musca), fig. 82. 7. Aptera (from α without, and πτερον a wing), insects having no wings. The last division contains scorpions, spiders, crabs, lobsters, &c. See Aranea, Cancer, &c.

Genera.—It is not necessary to insert here the characters of all the different genera which may be found in Linnæus's Syst. Nat. It will be sufficient to enumerate some new genera mentioned by subsequent systematic writers; so that by being acquainted with the subtile distinctions on which they are built, the student may avoid running into confusion. It is among the moderns only that genera of this kind are to be met with, and new names given them. To remove this difficulty, we shall first enumerate those names adopted by authors, which are synonymous with those of Linnæus.

New genera of authors synonymous with those of Linnæus.

In this account we shall distinguish the names which other authors have given by Italics. Thus, lucanus has been named *Platyceros*. Hister, *attelabus*. Byrrhus, *anthrenus cistela*. Mylabris, *laria* scop. Attelabus, *clerus*. Silpha, *peltis*. Bruchus, *mylabris*. Pitmus, *byrrhus*. Chrysomela, *galericula*. Hispa, *crioceris*. Cantharis, *cincindela*. Buprestis, *cucujus*. Carabus, *buprestis*. Myrmeleon, *formica-leo*. Sirex, *uroceros*.

New genera of authors.

Copris, scarabæus absque scutello. *Bostricius*, dermestes capucinus. *Cistela*, byrrhus pilula. *Rhinomancer*, attelabus rostro producto fere curculionis. *Anthribus*, silpha. *Bruchus*, ptinus fur ob spinas thoracis. *Melolontha*, chrysomela cylindrica. *Altica*, chrysomela saltatoria. *Diaperis*, chrysomela fungorum. *Pyrochora*, cantharis. *Telephorus*, cantharis. *Cantharis*, meloë alata. *Cerocoma*, meloë shafferi. *Notaxis*, meloë monoceros. *Prionus*, cerambyx thoracis margine denticulato. *Stenocoris*, leptura thorace spinosa. *Hydrophilus*, dytiscus antennis clavatis. *Mylabris*, necydalis minor. *Acridium*, gryllus muticus. *Locusta*, gryllus tettigonia.

Tettigonia, cicada. *Corixa*, notonecta. *Naucoceris*, nepa. *Perla*, hemerobius cauda bisecta. *Libelluloides*, myrmeleon antennis capitatis. *Crabro*, tenthredo antennis clavatis. *Pterophorus*, phalæna alucita. *Bibio*, tipula thoracе spinoso. *Stomoxoides*, asilus bucca inflata. *Strationymus*, musca. *Nemotelus*, musca. *Volucella*, musca.

These genera appear to be in a great measure like those which were introduced into botany by the followers of Rivinus. Paying too little regard to nature, they disunited natural genera, on account of the most trifling distinctions. This made their continuance in the science of very short duration. Our business here is not to suppose, but to examine, what nature will allow of, and what she will not. Knowledge of this kind, built on opinion only, will not stand. We are therefore to look into the science with great accuracy; and the larva of the insect, its manner of changing, and other things of moment, are to be known, before we presume to form a new genus.

Coining of new names, and changing of one old one for another, has been the source of the greatest confusion. Thus, in order to reduce the cicindela and carabus to the same genus, buprestis has been adopted for the generic name; but as that genus had long ago received a very different application, it was changed for that of cucujus. Again, that the officinal cantharides might be ranged among the cerambyces, the cantharides have been removed from the genus of meloë (to which they naturally belong), and refered to the genus of cicindela, obtaining thus a new name: and so of many others. Thus also, to mention no more, how needless and rash was it to seperate the acridium and locusta from the genus of gryllus, the crabro from the tenthredines, and the mylabris from the necydalis!

Trivial names.—The trivial names placed under their respective genera will occasion little or no controversy; they are current like money, and of the same utility as the proper names of men, Peter or Paul, &c. Insects living on vegetables should receive their names from the particular plants on which they mostly feed, as that method is preferable to all others. Thus the names of the phalæna mori, &c. are excellent; and when we are able to give such to insects, the old ones are to be discarded. But we are to be cautious and not too hasty in our judgment in this respect; as insects, when they cannot get their favourite food, will often eat other plants. Thus the silkworm, for want of mulberry-leaves, will eat those of lettuce, though it will not be so well nourished by them.

Various other instances of the invention of trivial names will be met with in the Systema Naturæ, particularly among the butterflies and moths. To prevent confusion from the great number of species which constitute the genus of phalæna, they are distributed into sections, and distinguished by the terms of bombyces, noctuæ, geometræ, tortrices, pyralides, tineæ, and alucitæ. The bombyces and noctuæ, which are so much alike, that the females of the bombyces, are with great difficulty distinguished from the noctuæ, are named in a promiscuous manner.

All those of the geometræ have their names terminating in aria and ata, according as their antennæ are setaceous or pectinated. The tortrices, in aria; the pyralides, in alis: the tineæ, in ella; and the alucitæ, in dactyla: so that it is evident from the termination itself to what section the insect is to be referred. It is to be wished that similar institutions could be formed throughout the whole science, as here the name itself serves to distinguish the insect.

Butterflies are divided into sections, by the names of equites, heliconii, danai, nymphales, and plebeii. In such a multitude of butterflies, the greatest part of which are foreign and extra-European, and to whose food and manner of life we are utter strangers, it was impossible to give significant trivial names. Linnæus, therefore, by way of simile, has taken the names of the equites from the Trojan history. These consist of two troops or bodies; of which one contains the sable, and as it were mourning nobles, having red or bloody spots at the basis of their wings. These receive names from the Trojan nobles; and as Priam was king of Troy, the most splendid among these bear his name. The other body, ornamented with a variety of gay colours, are distinguished by the names of the Grecian heroes; and as in both armies there were kings as well as officers of an inferior rank, those elegant butterflies, whose hinder wings resembled tails, were distinguished by some royal name. Thus when Paris is mentioned (knowing from history that he was a Trojan, and of royal blood), we find him among those of the first section; that is, those of a sable colour, spotted in the breast with red, and having their hinder wings resembling tails. When Agamemnon is named, we remember him to be a noble Greek, and find him among those nobles which have variegated and swallow-tailed wings. But when Nereus is spoken of, we readily know him to belong to the last section, having wings but no tails.

The second class, which contains the heliconii, derive their names from the muses, as Urania. The names of the sons and daughters of Danaus are bestowed on the third section. And as these species are subdivided into two other sections, viz. the white and parti-coloured, the metaphor is so conducted, that the white ones preserve the names of the daughters of Danaus, and the parti-coloured ones those of the sons of Egyptus: so that it is evident from the name itself to what section the butterfly is to be referred.

The names of the fourth section, nymphales, are taken from various nymphs of antiquity; and those of the fifth section, plebeii, are selected from different men among the ancients whose names are worthy of remembrance: so that by this means a knowledge of the ancients may be interspersed, and this agreeable science be made doubly pleasing. Those, therefore, who may find new lepidoptera, and give them new names, will do well to follow this method, unless it should be apparent what food the insect chiefly prefers for its subsistence.

ENTOYER, in heraldry, denotes a bordure charged wholly with things without life: it seems to be a corruption of the French entour round about.

ENTRING-LADDERS, in a ship, are of two sorts; one used by the vessel's sides, in a harbour, or in fair weather, for persons to go in and out of the ship: the other is made of ropes, with small staves for steps;

and is hung out of the gallery to enter into the boat, or to come aboard the ship, when the sea runs so high that they dare not bring the boat to the ship's side for fear of staving it.

ENTRY, writ of, is a writ directed to the sheriff, requiring him to command the tenant of the land, that he render to the demandment the premises in question, or appear in court on such a day, and show why he has not done it. Of this writ there are four kinds. 1. A writ of entry sur disseisin, that lies for the disseisee against the disseisor, upon a disseisin done by himself; and this is called a writ of entry in the nature of an assise. 2. A writ of entry sur disseisin in the per, for the heir by descent, who is said to be in the per, as he comes in by his ancestor. 3. A writ of entry sur disseisin in the per and cui, where the feoffee of a disseisor makes a feoffment over to another; and then the form of a writ is, that the tenant had no title to enter but by a prior alience, to whom the intruder demised it. A writ of entry sur disseisin in the post, which lies after a disseisin: the land is removed from hand to hand, in case of a more remote seisin, whereunto the other three degrees do not extend. 1 Inst. 238.

But all these writs are now disused, as the title of lands is now usually tried upon actions of ejectment or trespass.

ENTRY AD COMMUNEM LEGEM. The writ of entry ad communem legem lies where tenant in dower, or tenant by the courtesy, or for life, aliens in fee, or for the life of another, or in tail, the lands which they hold, &c. after their death, he in the reversion who has it in fee, or for life, shall have this writ against whomsoever is in possession of the land.

ENTRY AD TERMINUM QUI PRÆTERIIT: a writ of entry ad terminum qui præteriit, lies where a man leases lands or tenements for term of life, or years, and afterwards the term expires, and he to whom the lease was made, or a stranger, enters upon the land, and occupies the same, and deforces the lessor; the lessor or his heirs shall have the writ. And this writ lies in the per, cui, and post; for if the lessee holds over his term, and afterwards makes a feoffment, the lessor or heirs may have this writ against the feoffee in the per; and if the feoffee makes a feoffment over, he may have it against the second feoffee in the per and cui, and against the third feoffee in the post.

ENTRY IN CASU CONSIMILI. A writ of entry in casu consimili lies where tenant by the courtesy, or for life, or for another's life, aliens in fee, or in tail, or for life; now he in the reversion, who has an estate there for life, or in fee simple, or in tail, shall have that writ during the life of the tenant for life who alienes.

ENTRY IN CASU PROVISO. The writ of entry in casu proviso lies where tenant in dower aliens in fee, for life, or in tail, the land which he holds in dower; he who has the reversion in fee, or in tail, or for life, shall maintain that writ against the alienee, and against him who is the tenant of the freehold of land during the life of the tenant in dower, &c. and the writ may be made in the per, cui, and post.

ENTRY CAUSA MATRIMONII PRÆLOCUTI, lies where lands or tenements are given to a man, on condition that he shall take the donor to his wife within a certain time: and if he does not espouse her within the limited time, or espouses another, or otherwise disables himself, that he cannot take her according to the said condition, then the donor and her heirs shall have the said writ against him, or against whoever else is in the said land.

Bill of ENTRY, in commerce. See BILL. In England, in making entries inwards, it is usual for merchants to include all the goods they have on board the same ship in one bill, though sometimes they may happen to be upwards of twenty several kinds; and in case the goods are short-entered, additional or post-entries are now allowed, though formerly the goods so entered were forfeited. As to bills of entry outwards, or including goods to be exported, upon delivering them, and paying the customs, you shall receive a small piece of parchment called a cocket, which testifies your payment thereof, and all duties for such goods.

If several sorts of goods are exported at once, of which some are free, and others pay customs, the exporter must have two cockets, and therefore must make two entries; one for the goods that pay, and the other for the goods that do not pay custom.

Entries of goods on which a drawback is allowed, must likewise contain the name of the ship in which the goods were imported, the importer's name, and time of entry inwards. The entry being thus made, and an oath taken that the customs for those goods were paid as the law directs, you must carry it to the collector and comptroller, or their deputies; who, after examining their books, will grant a warrant, which must be given to the surveyor, searcher, or land-waiter, for them to certify the quantity of goods; after which the certificate must be brought back to the collector and comptroller, or their deputies, and oath made that the said goods are really shipped, and not landed again in any part of Great Britain.

ENVELOPE, in fortification, a work of earth, sometimes in form of a simple parapet, and at others, like a small rampart with a parapet: it is raised sometimes on the ditch, and sometimes beyond it. See FORTIFICATION.

ENVIRONNE', in heraldry, signifies surrounded with other things: thus, they say, a lion environne' with so many bezants. See BEZANT.

ENUMERATION, in rhetoric, a part of the peroration, in which the orator, collecting the scattered heads of what has been delivered throughout the whole, makes a brief and artful relation, or recapitulation thereof.

ENVOY, a person deputed to negotiate some affair with any foreign prince or state. Those sent from the courts of France, Britain, Spain, &c. to any petty prince or state, such as the princes of Germany, the republics of Venice, Genoa, &c. go in quality of envoys, not ambassadors; and such a character only do those persons bear who go from any of the principal courts of Europe to another, when the affair they go upon is not very solemn or important. There are envoys ordinary and extraordinary, as well as ambassadors; they are equally under the protection of the law of nations, and enjoy all the privileges of ambassadors, only differing from them in this, that the same ceremonies are not performed to them.

EPACRIS, in botany, a genus of the monogynia or-

der, in the pentandria class of plants. The calyx is a five-parted perianthium; the corolla monopetalous and tubular; the stamina five very short filaments; the pericardium a roundish, depressed, quinquelocular, quinquevalvular, gaping capsule; the seeds are numerous and very small. There are four species, natives of New Holland.

EPACT, in chronology, a number arising from the excess of the common solar year above the lunar, by which the age of the moon may be found every year.

The excess of the solar year above the lunar is 11 days; or the epact of any year expresses the number of days from the last new moon of the old year, which was the beginning of the present lunar year, to the 1st of January. On the first year of the cycle of the moon, the epact is 0, because the lunar year begins with the solar. On the second, the lunar year has begun 11 days before the solar year, therefore the epact is 11. On the third, it has begun twice 11 before the solar year, therefore the epact is 22. On the fourth, it begins three times 11 days sooner than the solar year, the epact would therefore be 33: but 30 days being a synodical month, that year must be intercalated; or that year must be reckoned to consist of 13 synodical months, and there remains three, which is the true epact of the year; and so on to the end of the cycle, adding 11 to the epact of the last year, and always rejecting 30, gives the epact of the present year. Thus to adjust the lunar year to the solar, through the whole of 19 years. 12 of them must consist of 12 synodical months each, and 7 of 13, by adding a month of 30 days to every year when the epact would exceed 30, and a month of 29 days to the last year of the cycle, which makes in all 209 days, *i. e.* 19 × 11; so that the intercalary or embolimæan years in this cycle are 4, 7, 10, 12, 15, 18, 19.

If the new moons returned exactly at the same time after the expiration of 19 years, as the council of Nice supposed they would do (when they fixed the rule for the observation of Easter, and marked the new moons in the calendar for each year of the lunar cycle), then the golden number multiplied by 11 would always give the epact. But in a Julian century, the new moons anticipate, or happen earlier than that council imagined they would, by $\frac{8}{25}$ of a day. In a Gregorian common century, which is one day shorter than a Julian century, they happen $\frac{17}{25}$ of a day later (1 day $-\frac{8}{25} = \frac{17}{25}$). Now $\frac{17}{25} \times 3 = \frac{51}{25}$ for the three common centuries but $\frac{8}{25}$ being subtracted, on account of the Gregorian bissextile century, there will remain $\frac{43}{25}$. Therefore in four Gregorian centuries, the new moons will happen later by $\frac{43}{25}$ of a day, and the epacts must be decreased accordingly.

At present the Gregorian epact is 11 days short of the Julian epact; but the quotient of the number of the centuries divided by 4, which at this time is 4, multiplied by $\frac{43}{25}$, with the addition of the remainder 1 multiplied by $\frac{17}{25}$, makes in all but $\frac{189}{25}$, or 7 days + $\frac{14}{25}$, therefore $\frac{86}{25}$, *i. e.* 3 days + $\frac{11}{25}$ must be added to complete the 11 days. Whence we have the following:

General rules for finding the Gregorian epact for ever. —Divide the centuries of any year of the Christian Era by 4 (rejecting the subsequent numbers); multiply the remainder by 17, and to this product add the quotient multiplied by 43; divide the product + 86 by 25; multiplying the golden number by 11, from which subtract the last quotient; and rejecting the thirties, the remainder will be the epact.

Example for 1816.

18 ÷ 4 = 4 remains 2
2 × 17 = 34
43 × 4 + 86 + 34 = 292
292 ÷ 25 = 11
11 × 12 = 132
132 — 11 = 121 ÷ 30 remains 1 = epact.

A shorter rule for finding the epact until the year 1900. Subtract 1 from the golden number; and multiplying the remainder by 11, reject the thirties, and you have the epact.

A table of golden numbers, and their corresponding epacts, till the year 1900.

G. No.	Epact.	G. No.	Epact.	G. No.	Epact.	G. No.	Epact.
1	0	6	25	11	20	16	15
2	11	7	6	12	1	17	26
3	22	8	17	13	12	18	7
4	3	9	28	14	23	19	18
5	14	10	9	15	4		

EPANORTHOSUS, in rhetoric, a figure by which a person corrects, or ingeniously revokes, what he just before alleged, as being too weakly expressed, in order to add something stronger, and more conformable to the passion with which he is agitated.

EPAULE, in fortification, denotes the shoulder of a bastion, or the place where its face and flank meet, and form the angle called the angle of the shoulder.

EPAULEMENT, in fortification, a work raised to cover sidewise, is either of earth, gabions, or facines, loaded with earth. The epaulement of the places of arms for the cavalry, at the entrance of the trenches, are generally of facines mixed with earth.

EPAULEMENT also denotes a mass of earth, called likewise a square orillon from its figure, raised to cover the cannon of a casement, and faced with a wall. It is likewise used for any work, thrown up to defend the flank of a post, or other place.

EPAULETTES, shoulder-knots. Among the French, all the degrees of rank, from a cadet to a general officer, were so minutely marked out by the epaulette, that a common centinel might instantly know what officer approached his station, and could pay the prescribed honours without hesitation or mistake.

This is not the case among the English. Some alterations have lately been made in those ornaments; but they are so partial, and confined to the upper ranks only, that it is impossible to distinguish the youngest ensign from the oldest captain by his epaulette, or by any other part of his uniform. When Highland or fusileer regiments are mixed with the line, every sentinel is still more perplexed, as all the officers belonging to those corps indiscriminately wear two epaulettes made of fringe and bullion of the same quality.

Epaulettes have lately been introduced into the British navy. The following are the gradations of rank

as distinguished by epaulettes. Masters and commanders have one epaulette on the left shoulder. Post-captains under three years, one epaulette on the right shoulder. And after having been post three years, two epaulettes. Rear-admirals have one star on the strap of the epaulette, vice-admirals two stars, and admirals three stars.

EPHA, or EPHAH, in Jewish antiquity, a measure for things dry, containing 1.0961 of a bushel.

EPHEDRA, in botany, a genus of the monodelphia order, in the diœcia class of plants, and in the natural method ranking under the 51st order, coniferæ. The male calyx is bifid; there is no corolla, but seven stamina; four antheræ inferior, three superior. The female calyx is bipartite, and five-fold, upon one another; there is no corolla; there are two pistils, and two seeds covered by the calyx, resembling a berry. There are two species, shrubs of Siberia.

EPHEMERA, the *day-fly*, or *May-fly*, in zoology, a genus belonging to the order of neuroptera. It has no teeth or palpæ; there are two large protuberances above the eyes; the wings are erect, the two hind ones being largest; and the tail is bristly. There are 11 species. These flies take their name of May-fly from the shortness of their life, and are distinguished into several species. Some live several days; others do not take flight till the setting of the sun, and live not to see the rising of that luminary. Some exist but one hour, others but half that time; in which short period they comply with the call of nature. With respect to those that live several days, Mr. Barbut observes, there is a peculiarity incident to themselves alone. They have to cast off one slough more, an operation which sometimes takes 24 hours to complete. To bring this about they cling fast to a tree. The ephemeræ, before they flutter in air, have in some manner been fishes. They remain in the states of larva and chrysalis for one, two, or three years. The chrysalis only differs from the larva by there being observable on its back cases for wings. Both have on their sides small fringes of hair, which, when put into motion, serve them as fins. Nothing can be more curious than the plying of those little oars in the water. Their abdomen is terminated, as well as in their state of flies, by three threads. These larvæ scoop themselves out dwellings in the banks of rivers; and they are small tubes made like siphons, the one serving for an entrance, the other affording them an outlet. The banks of some rivers are often perforated with them. When the waters decrease, they dig fresh holes lower down, in order to enjoy their element the water. The season and hour when the chrysalids of the different species of the ephemeræ turn into flies, maintain a kind of regularity. The heat, the rise or fall of the waters, accelerate, however, or postpone their final display. The ephemera of the Rhine appear in the air two hours before sunset. These flies are hatched almost all at the same instant in such numbers as to darken the air. The most early of those on the Marne and Seine in France do not begin to fly till two hours after the setting of the sun, towards the middle of August. They are seen fluttering and sporting on the brink of their tomb. The glare of light attracts them, round which they perform a thousand circles with amazing regularity. Their coming together for the purpose of generation can only be surmised, the shortness of their life requiring that all its functions should be proportionable to their duration. Some naturalists have been of opinion, that the males impregnate the eggs after the manner of fishes. The females, by the help of the threads of their tail and the flapping of their wings, support themselves on the surface of the water, and in that almost upright situation drop their eggs in clusters. One single female will lay 700 or 800 eggs, which sink to the bottom. The larva that escape from the voraciousness of the fishes, set about the construction of habitations to shelter them from every kind of danger. When the flies have propagated, they are seen to die, and fall by heaps. The land and water are strewed with them to a considerable thickness. The fishermen consider these multitudes of destroyed insects as manna for the fishes. See Plate LIII. Nat. Hist. fig. 180.

EPHEMERA, in medicine, the name of a species of fever continuing the space of one day, or sometimes more; for medical writers express themselves by ephemera simplex, vel plurium dierum. See MEDICINE.

EPHEMERA MALIGRA, is also a term by which some authors have called the sudor Anglicanus, or malignant diary fever, which generally destroyed the patient in 24 hours.

EPHEMERIDES, in astronomy, tables calculated by astronomers, showing the present state of the heavens for every day at noon; that is, the places wherein all the planets are found at that time. It is from these tables that the eclipses, conjunctions, and aspects of the planets, are determined; and horoscopes or celestial schemes constructed.

In England, the Nautical Almanac, or Astronomical Ephemeris, published annually by anticipation, under the direction of the commissioners of longitude, is the most considerable. In France, celestial ephemerides were published by M. Desplaces every ten years, from 1715 to 1745: they were afterwards continued by the abbe' Caille, with many additions; of which an account may be seen in the History of the Academy of Sciences for 1748. The Academy of Sciences have likewise published annually, from the beginning of the last century, a kind of ephemeris, under the title of Connoissance des Tems.

EPHELIS, a genus of the class and order octandria monogynia. The calyx is five-parted; petals five-clawed; nect. ten-scales; capsule oblong. There is one species, a tree of Guiana.

EPHOD, in Jewish antiquity, one part of the priestly habit; being a kind of girdle, which, brought from behind the neck over the two shoulders, and hanging down before, was put across the stomach, then carried round the waist, and made use of as a girdle to the tunic.

There were two sorts of ephods, one of plain linen for the priests, and the other embroidered for the high-priest. Of this last Moses gives an ample description. It was composed of gold, blue, purple, crimson, and twisted cotton. Upon part of it, which passed over the shoulders, were two large precious stones, one on each shoulder: upon these were engraved the name of the twelve tribes, six upon each stone.

The ephod was peculiar to the priesthood, and thought essential to their character; it being the opinion of the

Jews, that no worship, true or false, could subsist without a priesthood and ephod.

EPHORI, in Grecian antiquity, magistrates established in ancient Sparta to balance the regal power. The authority of the ephori was very great. They sometimes expelled and even put to death the kings, and abolished or suspended the power of the other magistrates, calling them to account at pleasure. There were five of them, others say nine. They presided in the public shows and festivals. They were entrusted with the public treasure, made war and peace, and were so absolute, that Aristotle makes their government equal to the prerogative of a monarchy. They were established by Lycurgus.

EPIBATERIUM, a genus of the monœcia hexandria class and order. The calyx is double; petals six; drupes three, subglobular, muconate, &c. There is but one species.

EPIC, or *heroic poem*. See POETRY.

EPICEDIUM, in ancient poetry, a poem rehearsed during the funeral solemnity of persons of distinction. We find two beautiful epicediums in Virgil, one of Euryalus, and the other of Pallas.

EPICHIREMA, in logic, a mode of reasoning, which comprehends the proof of one or both the premises of a syllogism, before the conclusion is drawn.

EPICŒNE, in grammar, a term applied to nouns, which, under the same gender and termination, mark indifferently the male and female species.

EPICYCLE, in the ancient astronomy, a little circle whose centre is in the circumference of a greater circle; or it is a small orb, or sphere, which being fixed in the deferent of a planet, is carried along with it; and yet, by its own peculiar motion, carries the planet fastened to it round its proper centre. It was by means of epicycles that Ptolemy and his followers solved the various phenomena of the planets, but more especially their stations and retrogradations.

The great circle they called the excentric or deferent, and along its circumference the centre of the epicycle was conceived to move; carrying with it the planet fixed in its circumference, which in its motion downwards proceeded according to the order of the signs, but, in moving upwards, contrary to that order. The highest point of a planet's epicycle they called apogee, and the lowest perigee.

The length of any part of the curve of an epicycloid, which any given point in the revolving circle has described, from the position where it touched the circle upon which it revolved, is to double the versed sine of half the arc which all the time of revolving touched the quiescent circle, as the sum of the diameters of the circles, is to the semidiameter of the quiescent circle in the exterior cycloid; or as the difference of the diameters is to that semidiameter, for the interior one.

Dr. Halley has given a general proposition for the measuring of all cycloids and epicycloids: thus, the area of a cycloid, or epicycloid, either primary, or contracted, or prolate, is to the area of the generating circle; and also the areas of the parts generated in those curves, to the areas of analogous segments of the circle; as the sum of double the velocity of the centre and the velocity of the circular motion, is to this velocity of the circular motion. See Philos. Trans. No. 218.

EPICYCLOIDS, *spherical*, are formed by a point of the revolving circle, when its plane makes a constant angle with the plane of the circle on which it revolves.

If a parabola roll upon another equal to it, its focus will describe a right line perpendicular to the axis of the quiescent parabola; also the vertex of the rolling parabola will describe the cissoid of Diocles; and any other point of it will describe some one of Newton's defective hyperbolas, having a double point in the point of the quiescent parabola.

In like manner, if an ellipse revolve upon another ellipse, equal and similar to it, its focus will describe a circle, whose centre is in the other focus, and consequently the radius is equal to the axis of the ellipsis; and any other point in the plane of the ellipse will describe a line of the 4th order.

The same may be said also of an hyperbola, revolving upon another, equal and similar to it; for one of the foci will describe a circle, having its centre in the other focus, and the radius will be the principal axis of the hyperbola; and any other point of the hyperbola will describe a line of the 4th order.

Concerning these lines, see Newton's Principia, lib. 1; see also Maclaurin's Geometria Organica.

EPICYCLOID, in geometry, a curve generated by the revolution of the periphery of a circle, ACE (Pl. LIV. Miscel. fig. 84), along the convex or concave side of the periphery of another circle, DGB.

The length of any part of the curve, that any given point in the revolving circle has described, from the time it touched the circle it revolved upon, shall be to double the versed sine of half the arch, which all that time touched the circle at rest, as the sum of the diameters of the circle, to the semidiameter of the resting circle, if the revolving circle moves upon the convex side of the resting circle; but if upon the concave side, as the difference of the diameters, to the semidiameter of the resting circle.

EPIDEMIC. See MEDICINE.

EPIDENDRUM, a genus of the diandria order, in the gynandria class of plants, and in the natural method ranking under the 7th order, orchideæ. The nectarium is turbinated, oblique, and reflexed. There are 124 species, one of which is the plant which produces the fruit called vanilla, and which is used in the making of chocolate. It is a native of Mexico, and also of some parts of the East Indies. It is a parasitic plant; the leaves of which greatly resemble the vine, and are about eighteen inches long and three inches broad. The flowers are of a white colour intermixed with stripes of red and yellow. When these fall off they are quickly succeeded by the pods, which at first are green, but afterwards, as they ripen, become yellow, and are gathered for use. The pods of the best vanilla are long, slender, and well filled with seeds. If opened when fresh, the cavity of the pod is found to contain a humid substance that is black, oily, and balsamic, of such a strong smell, that it frequently causes headaches, and even a sort of temporary intoxication. The season for gathering the pods begins about the end of September, and lasts till the end of December. They are dried in the shade; and when dry, and fit for keeping, they are rubbed externally with a little oil of cocoa or calba, to render them sup-

ple, or preserve them the better, and to prevent them from becoming too dry or brittle. The use of this fruit is only for perfuming chocolate. In New Spain it is reckoned unwholesome, and therefore never used; but in England, and other countries of Europe, it is a constant ingredient; and perhaps its noxious qualities may be corrected by the sea air. In those countries where they grow, the plants are very easily propagated by cuttings. In this country they require to be kept in a stove, and also to be placed near some American tree, round which they may climb for their support.

EPIDERMIS. See CUTIS.

EPIDIDYMIS, in anatomy, the name by which some call the two bodies more usually known by that of parastatæ.

EPIGASTRIC REGION, a part or sub-division of the abdomen.

EPIGRAM, in poetry, a short poem in verse, treating only of one thing, and ending with some lively, ingenious, and natural thought, or point. See POETRY.

EPIGRAPHE, among antiquarians, denotes the inscription of a building, pointing out the time when, the persons by whom, the uses, &c. for which it was erected.

EPILEPSY, in medicine, the same with what is otherwise called the falling-sickness, from the patient's falling suddenly to the ground. Sometimes this disease comes upon the patient unawares: but it more frequently gives notice of its approach by a lassitude of the whole body, a heavy pain in the head, with some disturbance of the senses, unquiet sleep, unusual dread, dimness of sight, and a noise in the ears: in some there are a violent palpitation of the heart, a puffing or inflation of the breast, difficult respiration, a murmuring noise in the belly, fetid stools, a flux of the urine, and a refrigeration of the joints: in others, there is a sensation as it were of cold air, ascending from the extreme parts towards the brain and heart. At length falling senseless to the ground, the thumbs are shut up close in the palms of the hands, and are with difficulty taken out; the eyes are distorted or inverted, so that nothing but the whites appears; all sensation is suspended, insomuch that no smell, no noise, nor even pinching of the body, is able to bring them to themselves; they froth at the mouth, with a hissing kind of noise: the tongue is lacerated, or torn by the teeth, and there is a shaking or trembling of the joints. However, in different patients, the symptoms vary; for sometimes, instead of convulsive motions, the limbs are all stiff, and the patient is as immoveable as a statue. At last there is a remission of the symptoms, and the patients come to themselves after a longer or shorter interval: then they complain of a pain and heaviness of the head, and a lassitude of all their joints. These fits usually return on certain days, or age of the moon, but especially about the new or full moon; in women chiefly about the time of menstruation: and as to the prognostics, they generally leave the patient about the time of puberty. See MEDICINE.

EPILOBIUM, the WILLOW-HERB, in botany; a genus of the monogynia order, in the octandria class of plants; and in the natural method ranking under the 17th order, calycanthemæ. The calyx is quadrifid; the petals four; the capsule oblong, inferior; the seeds pappous or downy. There are fourteen species, several of them natives of Britain. They grow in marshes, or under hedges in moist and shady places; having blossoms generally of a red colour, and sometimes of considerable beauty. The most remarkable is the hirsutum, commonly called codlins-and-cream. The top-shoots of this plant have a very delicate fragrancy; but so transitory, that before they have been gathered five minutes it is no longer perceptible. Horses, sheep, and goats, eat this plant; cows are not fond of it; swine refuse it. An infusion of the leaves of another species, the angustifolium, or rose-bay willow-herb, has an intoxicating quality, as the inhabitants of Kamtschatka have learned. These people also eat the white young shoots which creep under the ground, and have a sort of ale brewed from the dried pith of it. The down of the seeds has been lately manufactured by mixing it with cotton, or beaver's hair.

EPILOGUE, in oratory, the end or conclusion of a discourse, ordinarily containing a recapitulation of the principal matters delivered.

EPILOGUE, in dramatic poetry, a speech addressed to the audience after the play is over, by one of the principal actors, usually containing some reflections on certain incidents in the play, especially those on the part of the person that speaks it. See POETRY.

EPIMEDIUM, BARREN-WORT, in botany; a genus of the monogynia order, in the tetandria class of plants; and in the natural method ranking under the 24th order, corydales. There are four nectaria, cup-shaped, and lying on the petals. The corolla is tetrapetalous, the calyx dropping off. The seed-vessel is a pod. There is only one species, viz. the alpinum. It is a low herbaceous plant, with a creeping root, having many stalks about nine inches high, each of which has three flowers, composed of four leaves placed in the form of a cross. They are of a reddish colour, with yellow stripes on the border.

EPIPHANY, a Christian festival, otherwise called the manifestation of Christ to the Gentiles, observed on the sixth of January, in honour of the appearance of our Saviour to the three magi, or wise men, who came to adore him, and bring him presents. The feast of epiphany was not originally a distinct festival, but made a part of that of the nativity of Christ, which being celebrated twelve days, the first and last of which were high or chief days of solemnity, either of these might properly be called epiphany, as that word signifies Christ's appearance in the world. The kings of England and Spain offer gold, frankincense, and myrrh, on epiphany, or twelfth-day, in memory of the offerings of the wise men to the infant Jesus. The festival of epiphany is called by the Greeks the feast of lights, because our Saviour is said to have been baptised on that day, and baptism is by them called illumination.

EPIPHONEMA, in rhetoric, a sententious exclamation containing a lively remark placed at the end of a discourse or narration; such is that of Virgil,

> Fas omne abrumpit, Polydorum obtruncat, et auro
> Vi potitur. Quid non mortalia pectora cogis,
> Auri sacra fames?

This figure closes a narration in a very advantageous manner, deeply impresses the thing related upon the memory of the reader, and leaves him well pleased with the sense and sagacity of the author.

EPIPHYSIS, in anatomy, a bony substance, or as it were a lesser bone, affixed to a larger or principal bone by the intervention of a cartilage. See ANATOMY.

EPISODE, in poetry, a separate incident, story, or action, which a poet invents, and connects with his principal action, that his work may abound with a greater diversity of events: though, in a more limited sense, all the particular incidents of which the action or narration is compounded, are called episodes. The episode, in its original, was only something rehearsed between the parts of the chorus, or ancient tragedy, for the diversion of the audience. Episodes serve to promote the action, to illustrate, embellish, and adorn it, and carry it to its proper period. Episodes are either absolutely necessary, or very requisite. All episodes are incidents, though all incidents are not episodes; because some incidents are not adventitious to the action, but make up the very form and series of it. Examples will clear up this distinction: the storm in the first Æneid of Virgil, driving the fleet on the coast of Carthage, is an incident, not an episode, because the hero himself, and the whole body of his forces, are concerned in it; and so it is a direct and not a collateral part of the main action. The adventures of Nisus and Euryalus, in the ninth Æneid, are episodes, not incidents, *i. e.* not direct parts of the main action. See POETRY.

EPISTATES, in the Athenian government, was the president of the proedri. To the custody of this officer was committed the public seal, and the keys of the citadel and the public exchequer; this therefore was an office of so great trust and power, that no man was permitted by the laws to continue in it above one day, nor to be elected into it a second time. The epistates were elected by lot out of the prytanes.

EPISTEMONARCH, in the ancient Greek church, an officer of great dignity, who had the care of every thing relating to faith, in the quality of censor. His office answered pretty nearly to that of master of the sacred palace at Rome.

EPISTROPHE, in rhetoric, a figure wherein that which is supposed of one thing, is strongly affirmed of another: thus, Are they Hebrews? So am I. Are they Israelites? So am I. Are they of the seed of Abraham? So am I, &c.

EPISTYLE, in the ancient architecture, a term used by the Greeks for what we call architrave. See ARCHITECTURE.

EPITHALAMIUM, in poetry, a nuptial song, or composition, in praise of the bride and bridegroom, praying for their prosperity, for a happy offspring, &c.

EPITHET, in poetry and rhetoric, an adjective expressing some quality of a substantive to which it is joined; or such an adjective as is annexed to substantives by way of ornament and illustration, not to make up an essential part of the description.

EPITOME, in literary history, an abridgement or summary of any book, particularly of a history. See ABRIDGMENT.

EPITRITUS, in prosody, a foot consisting of three long syllables, and one short. Of these grammarians reckon four kinds; the first consisting of an iambus and spondee, as sălūtāntēs; the second of a trocheus and spondee, as cōncĭtātī: the third of a spondee and an iambus, as cōmmūnĭcāns: and the fourth of a spondee and a trocheus, as incāntārĕ.

EPITROPUS, among the modern Greeks, a kind of arbitrator chosen by the Greek Christians under the dominion of the Turks, to terminate their differences, and avoid carrying them before the Turkish magistrates.

EPIZEUXIS, in rhetoric, a figure which repeats the same word, without any other intervening; such is that of Virgil, Nunc, nunc, insurgite remis.

EPOCHA, in chronology, a term or fixed point of time, whence the succeeding years are numbered or accounted. The most remarkable epochas are those that follow.

EPOCHA *of the creation of the world.* According to the Vulgate, archbishop Usher places this event 4004 years before the birth of Christ; Scaliger makes it 3950, Petavius 3984, and Ricciolus 4184 years before Christ. According to the Septuagint, Eusebius places the creation 5200 years before the nativity of our Lord; the Alphonsine tables, 6984; and Ricciolus 5634. The creation, therefore, as we follow the archbishop, happened in the year 710 of the Julian period. Sir Isaac Newton, again, makes the creation of the world later by 500 years than all other chronologists; and the proofs by which this illustrious philosopher supports his opinion are of two different kinds. The Egyptians counted 341 generations from Menes to Setho, allowing a hundred years for three generations; and the ancient Greeks computed one generation at about forty years. Now, says sir Isaac, it is true, three ordinary generations may be computed at about 120 years; but generations are longer than the reign of kings, because it is evident that mankind in general live longer than kings reign. The duration of a reign, therefore, taking one with another, is according to him about twenty years: whence he concludes, that the ancients have erred in their calculation in allowing forty years for every generation. The second kind of proof is taken from the precession of the equinoxes. According to Clemens Alexandrinus, Chiron, who was in the expedition of the Argonauts, fixed the vernal equinox at the fifteenth degree of Aries, and consequently the summer solstice at the fifteenth degree of Cancer. Meto fixed the summer solstice at the eighth degree of Cancer, a year before the Peloponnesian war. Now since one degree answers to the retrograde motion of the equinoctial points in 72 years, there are seven times 72 years from the expedition of the Argonauts to the beginning of the Peloponnesian war: that is, 504 years, and not 507 years, as the Greeks affirm. By combining these two different proofs, sir Isaac concludes, that the expedition of the Argonauts ought to be placed 909 years before Jesus Christ, and not 1400, as is generally believed; and therefore that the creation of the world ought to be placed about 500 years later than chronologists generally place it.

EPOCHA *of the deluge.* According to the Hebrew text, there are 1656 years from the creation to the deluge; 1307 according to the Samaritan; 2242, according to Eusebius and the Septuagint; 2256, according to Josephus and the Septuagint; and 2262 according to Julius Africanus, Petavius, and the Septuagint. In following the Hebrew text this epocha begins in the year 2366 of the Julian period.

Epocha *of the olympiades*, used principally by the Greeks, had its origin from the olympic games, which were celebrated at the beginning of every fifth year. This epocha begins 776 years before the incarnation, or in the year 3938 of the Julian period.

Epocha, *Varronian, of the building of Rome*, is fixed 753 years before our Saviour's birth, and in the year 3961 of the Julian period.

Epocha, *of Nabonassar king of Babylon*, made use of by Ptolemy, Censorinus, and several other authors, began 747 years before the incarnation, and in the year 3967 of the Julian period.

Epocha, *Julian*. The first year of Julius Cæsar's correcting the calender stands 45 years before our Saviour's birth, and coincides with the year 4669 of the Julian period.

Epocha *of Christ*. The Christian world generally reckoned from the epocha of the creation, the building of Rome, the consuls' register, or the emperor's reign, till about 500 years after Christ, when the epocha of the nativity of our blessed Lord was introduced by Dionysius Exiguus. He began his account from the conception or incarnation, properly called Lady-day. Most countries in Europe, however, at present reckon from the first of January next following, except the court of Rome, where the epocha of the incarnation still obtains for the date of their bulls and briefs. But here we are to observe, that there are different opinions respecting the year of our Saviour's birth. Capellus and Kepler fix it at about the 758th year from the building of Rome. Deckar and Petavius place the incarnation in the 749th of Rome. Scaliger and Vossius make it fall on the 751st of Rome. Dionysius Exiguus, Bede, &c. fix the birth of our Saviour to the year 751 of Rome; the diversity of these opinions proceeding from the difficulty of fixing Herod the Great's death, who, as is evident from the evangelists, was living at our Saviour's birth, the taxation of Cyrenius, and the time of our Saviour's beginning his ministry. But it is generally agreed, that as to computation and use, the common epocha is to be followed which places the birth of Christ in the 4713th of the Julian period, although the true birth rather corresponds with the 4711th of the same period.

Epocha, *Dioclesian*, or Epocha *of Martyrs*, called also the æra of the Cophti or Egyptians, because the emperor Diocleslan made a great many martyrs in Egypt, begins in the year 283 of our Lord, and the 4997 of the Julian period.

Epocha *of the hegira* or flight of Mahomet, used among the Turks, is the year of the Julian period 5335, answering to the year of Christ 622.

Epocha, *Persian* or *Yezdejerd*, is the year of the Julian period 5345, answering to the year 622. To reduce the years of one epocha to those of another, observe the following rule; add the given year of an epocha to the year of the Julian period corresponding with its rise, and that will give the year of the period. For example, if to 1816, the present year of the Christian epocha, we add 4723, the year of the Julian period corresponding with its rise, the sum, 6539, will be the present year of the Julian period; now if we substract from the year thus found, the year of the Julian period corresponding with the rise of any epocha, the remainder shows the true method of making a just connection betwixt that epocha and the known year of Christ. Again, if we want to find the year of the Julian period corresponding to a given year before Christ, we subtract the given year from 4714, and the remainder is the year required. See Chronology.

EPODE, in lyric poetry, the third or last part of the ode; the ancient ode being divided into strophe, antistrophe, and epode. The epode was sung by the priests, standing still before the altar, after all the turns and returns of the strophe and antistrophe, and was not confined to any precise number or kind of verses. The episode is now a general name for all kinds of little verses that follow one or more great ones, of what kind soever they be; and, in this sense, a pentameter is an epode after an hexameter. And as every little verse, which being put after another, closes the period, is called epode, hence the sixth book of Horace's odes is entitled Liber Epodon, Book of Epodes; because the verses are all alternately long and short, and the short ones generally, though not always, close the sense of the long one.

EPOPŒIA, in poetry, the story, fable, or subject treated of, in an epic poem.

EPULONES, in Roman antiquity, ministers who assisted at the sacrifice, and had the care of the sacred banquet committed to them. At first they were only three in number, but afterwards increased to seven. Their office was, to give notice when feasts were to be held in honour of the gods, and to take care that nothing was wanting towards the celebration.

EQUABLE, an appellation given to such motions as always continue the same in degree of velocity, without being either accelerated or retarded. When two or more bodies are uniformly accelerated or retarded, with the same increase or diminution of velocity in each, they are said to be equally accelerated or retarded.

EQUATION, in algebra, the mutual comparing two equal things of different denominations, or the expression denoting this equality; which is done by setting the one in opposition to the other, with the sign of equality (=) between them: thus $3s. = 36d.$, or 3 feet $= 1$ yard. Hence, if we put a for a foot, and b for a yard, we will have the equation $3a = b$, in algrebraic characters. See Algebra.

Equation *of a curve*, an equation expressing the nature of a curve, the relation between an abciss and a corresponding ordinate, or the relation of their fluxions. See Curve.

Equation *of time*, in astronomy and chronology, the reduction of the apparent time or motion of the sun, to equable, mean, or true time. See Astronomy.

EQUATOR, in geography, a great circle of the terrestrial globe, equidistant from its poles, and dividing it into two equal hemispheres; one north, and the other south. See Globes, *use of*.

EQUATORIAL, *universal* or Portable Observatory, is an instrument intended to answer a number of useful purposes in practical astronomy, independant of any particular observatory. It may be employed in any steady room or place, and it performs most of the useful problems in the science of astronomy. See Observatory.

EQUERRY, in the British customs, an officer of state under the master of the horse. There are five equerries,

who ride abroad with his majesty; for which purpose they give their attendance monthly, one at a time, and are allowed a table. As to the equerries of the crown-stable, they have this distinct appellation, as being employed in mounting, managing, and breaking, the saddle-horses for his majesty's use, and holding his stirrup.

EQUES AURATUS, is used for a knight bachelor, called *auratus*, q. d. *gilt*, because anciently none but knights were allowed to beautify their armour, or other habiliments of war, with gold. This term is not used in law, but instead of it *miles* and *chevalier* are made use of.

EQUESTRIAN STATUE, signifies the statue of a person mounted on horseback.

EQUESTRIAN ORDER, among the Romans, signified their knights or equites, as also their troopers or horsemen in the field; the first of which orders stood in contradistinction to the senators, as the last did to the foot, military, or infantry: each of these distinctions was introduced into the state by Romulus.

EQUIANGULAR, in geometry, an epithet given to figures whose angles are all equal: such are square equilateral triangles, &c.

EQUIDIFFERENT NUMBERS, in arithmetic, are of two kinds. 1. Continually equidifferent is when, in a series of three numbers, there is the same difference between the first and second, as there is between the second and third; as 3, 6, 9. And 2. Discretely equidifferent is when, in a series of four numbers or quantities, there is the same difference between the first and second as there is between the third and fourth: such are 3, 6, 7, 10.

EQUIDISTANT, an appellation given to things placed at an equal distance from some fixed point, or place, to which they are referred.

EQUILATERAL, in general, something that has equal sides, as an equilateral triangle.

EQUILATERAL HYPERBOLA, one whose transverse diameter is equal to its parameter; and so all the other diameters, equal to their parameters; in such an hyperbola, the asymptotes always cut one another at right angles in the centre. Its most simple equation, with regard to the transverse axis, is $y^2 = x^2 - a^2$; and, with regard to the conjugate, $y^2 = x^2 \times a^2$, when a is the semi-transverse, or semiconjugate. The length of the curve cannot be found by means of the quadrature of any space, of which a conic section is in any part of the perimeter.

EQUILIBRIUM, in mechanics, is when the two ends of a lever or balance hang so exactly even and level, as neither to ascend or descend, but keep in a position parallel to the horison; which is occasioned by their being both charged with an equal weight.

EQUIMULTIPLES, in arithmetic and geometry, are numbers or quantities multiplied by one and the same number or quantity. Hence, equimultiples are always in the same ratio to each other, as the simple quantities before multiplication: thus if 6 and 8 are multiplied by 4, the equimultiples 24 and 32 will be to each other as 6 to 8.

EQUINOCTIAL, a great circle in the heavens under which the equator moves in its diurnal motion. The poles of this circle are the poles of the world. It divides the sphere into two equal parts, the northern and southern. It cuts the horison of any place, in the east and west points; and at the meridian its elevation above the horizon is equal to the co-latitude of the place. The equinoctial has also various other properties; as,

1. Whenever the sun comes to this circle, he makes equal days and nights all round the globe; because he then rises due east, and sets due west. Hence it has the name equinoctial. All stars which are under this circle, or have no declination, also rise due east, and set due west.

2. All people living under this circle, or upon the equator or line, have their days and nights at all times equal to each other.

3. From this circle, on the globe, are counted, upon the meridian, the declination in the heavens, and the latitude on the earth.

4. Upon the equinoctial, or equator, is counted the longitude, making in all 360° quite round, or else 180° east and 180° west.

5. And as the time of one whole revolution is divided into 24 hours, therefore one hour answers to 15°, or the 24th part of 360°. Hence,

1° of longitude answers	to 4 minutes of time,
15′	to 1 minute of time,
1′	to 4 seconds of time, &c.

6. The shadows of those people who live under this circle are cast to the southward of them for one half of the year, and to the northward of them during the other half; and twice a year, viz. at the time of the equinoxes, the sun at noon casts no shadow, being exactly in their zenith.

EQUINOX, the time when the sun enters either of the equinoctial points, where the ecliptic intersects the equinoctial.

It is so called, because when the sun is in these points, the days and nights are of an equal length all the world over. As the sun is in one of them in the spring, viz. about the 20th of March, it is called the vernal equinox; and in the other in autumn, viz. about Sept. 23d, it is called the autumnal equinox.

As the sun's motion is unequal, being sometimes quicker and sometimes slower, it happens that there are about 8 days more from the vernal to the autumnal equinox, or while the sun is on the northern side of the equator, than while he is moving through the southern signs from the autumnal to the vernal equinox. According to Cassini the sun is

186	d.	14h.	53m.	in the N. signs
178		14	56	in the S. signs.
7		23	57	is the difference of them,

or nearly 8 days.

EQUINOXES, *precession of.* Astronomers consider the year under two distinctions; viz. the solar and the astral. The tropical or solar year, upon which the seasons depend, is the exact time in which the sun moves all round from one equinox to the same again, and which period has been found to be equal to 365 days, 5 hours, 48′, 49″. The astral year is the time that the sun employs in going from one fixed part of the heavens, viz. from a given fixed star, all round, and again to the same precise point of the heavens; and this period, or astral year, is a little longer than that of the solar year, viz. it is equal to 365 days, 6 hours, 9′, 12″, which is longer than the solar year by 20′, 23″, of time, or to an arch of 50″. 25

(for in 20′ 25″ of time, the sun runs through an arch of 50″. 25;) so that the sun, as seen from the earth, arrives at the equinoctial point, viz. at the equator, a little before it arrives at that same precise point of the heavens with which it coincided when it crossed the equator in the preceding year. This difference between the period of the sun's going from one equinox to the same, and the period of its going from a given star, or part of the heavens, to the same again, is called the precession of the equinoxes. This precession in one year is very trifling; but the accumulation of it, after a number of years, produces a considerable difference, which can by no means be passed unnoticed; thus, in a hundred years (which is called the secular precession) it amounts to 1°, 23′, 45″; and the difference which it has produced since the stars were first observed, and their positions were delineated, is very striking.

How can the sun return to the same equinox at the end of every year, without returning to the same spot in the heavens, or to the same fixed star? is the usual difficulty. In order to clear this difficulty, the reader must recollect that the equator is a circle which, being equidistant from the poles, divides the celestial sphere into two equal portions. Now, if the poles were stationary, viz. coincided constantly with the same spots in the heavens, then the equator would likewise pass constantly over the same fixed stars, and would cut the ecliptic constantly at the same points; for the ecliptic is an invariable circle, viz. it passes always over the same stars. But it has been observed, that the poles are subject to a constant, though very small, movement: so that if at one time any of the two points in the heavens, which do not revolve with the daily revolution of the rest of the sphere, and which we for that reason call the poles, be near a certain star, some years after it will be found near some other star; or, in other words, the polar star is not always the same. It appears, from the result of calculations established upon the observation made during several centuries, that the path of either of the poles is a circle, the poles of which coincide with the poles of the ecliptic, and that the pole will move along that circle so very slowly, as to accomplish the whole revolution in 25791 years nearly. The diameter of this circle is equal to twice the inclination of the ecliptic to the equator, viz. to about 47°.

Now, as the ecliptic is a fixed circle in the heavens; but the equator, which must be equidistant from the poles, moves with the poles; therefore the equator must be constantly changing its intersection with the ecliptic. And from the best observations it appears that the equator cuts the ecliptic every year 50″. 25 more to the westwards, than it did the year before: hence the sun's arrival at the equinoctial point *precedes* its arrival at the same fixed spot of the heavens every year by 20′ 25″ of time, or by an arc of 50″. 25. Thus, by little and little, these equinoctial points will cut the ecliptic more and more to the westward, until, after the long period of 25791 years, they will cut it again at the same point precisely.

The 12 constellations, which, as has been mentioned in the preceding pages, occupy the whole of the zodiac, have given their names to 12 equal portions of the ecliptic, each portion consisting of 30°; and each portion was marked by the sign, mark, or character, peculiar to the constellation to which it belonged, or with which it coincided, when the constellations were first noticed, at which time the vernal equinox took place in the constellation of Aries, the summer solstice in that of Cancer, &c.: but on account of the precession of the equinoxes, the constellations no longer coincide with these points; for instance, the vernal equinox is in the constellation of Pisces, and the constellation of Aries is now considerably removed from it, and is gone nearer to the summer solstice: and so are all the other constellations removed, yet their characters have been left to denote the same parts of the ecliptic; thus the vernal equinox is called the first point of Aries, and is marked ♈: and so of the rest.

From what has been said above, it appears that not only the equinoctial points, but also the solstitial points, must change accordingly.

EQUISETUM, *horse-tail*, a genus of the order of filices, in the cryptogamia class of plants, and in the natural method ranking under the 51st order, coniferæ. There is a spike of peltated or shielded fructifications opening at the base. There are seven species, of which the most remarkable are:

1. The sylvaticum, or wood horse-tail. It grows in woods and moist shady places in many parts of England and Scotland. The stalk rises from 12 to 18 inches high, angular, and rough to the touch; the angles being edged with sharp spiculæ, scarcely visible without a microscope. The leaves grow verticillate, 12 or more in a whorl, and these whorls are about an inch distant from one another. The leaves are very slender, nearly quadrangular, about five inches long, pendent, and beset with several other secondary whorls, so that it resembles a pine-tree in miniature. Horses are very fond of this plant, and in some parts of Sweden it is collected to serve them as winter food.

2. The arvense, common or corn horse-tail, grows in wet meadows and corn-fields. The most remarkable property of this is, that its seeds, when viewed by a microscope, are seen to leap about as if they were animated. It is a troublesome plant in pastures; and disagreeable to cows, being never touched by them unless they are compelled by hunger, and then it brings on an incurable diarrhœa. It does not seem to effect horses or sheep.

3. The palustræ, marsh horse-tail, or paddock-pipe, is frequent in marshes and ditches. It is not so rough as the former, but is likewise prejudicial to cattle.

4. The fluviatile, or great river horse-tail, is frequent in shady marshes, and on the brinks of stagnant waters. It is the largest of all the species, growing sometimes to the height of a yard, and near an inch in diameter. Haller tells us, that this kind of equisetum was eaten by the Romans; and Linnæus affirms that oxen and rein-deer are fond of it, but that horses refuse it.

5. The hiemale, rough horse-tail, shave-grass, or Dutch rushes. This is much used by the whitesmiths and cabinet-makers, under the name of Dutch rushes, for polishing their metals and wood. The fact is, that there is a portion of flint, which exists in this plant near the surface, in the form of very fine grains, which enables it to perform this office. All the other species will answer this purpose in some degree, but the last better than any of the rest. In Northumberland the dairy-maids scour and

clean their milk-pails with it. Some imagine that if cows are fed with this species their teeth will fall out.

EQUITY, is a construction made by the judges, that cases out of the letter of a statute, yet being within the same mischief or cause of making the same, shall be within the same remedy that the statute provides. And the reason is, that the lawmaker could not possibly set down all cases in express terms: thus, though it may be unlawful to kill a man, yet it is not unlawful for one to kill another assaulting him, in order to preserve his own life. 4 Inst. 24.

EQUITY OF REDEMPTION ON MORTGAGES. If where money is due on a mortgage, the mortgagee is desirous to bar the equity of redemption, he may oblige the mortgagor either to pay the money, or be foreclosed of his equity, which is done by proceedings in the court of chancery.

EQUITY also frequently signifies the court of chancery, where controversies are determined which do not properly come under any express law. See CHANCELLOR.

EQUIVALENT, an appellation given to things which agree in nature, or other circumstances, as force, virtue, &c.

EQUIVOCAL TERMS or WORDS, among logicians, are those which have a doubtful or double meaning.

According to Mr. Locke, the doubtfulness and uncertainty of words has its cause more in the ideas themselves, than in any incapacity of the words to signify them; and might be avoided, would people always use the same term to denote the same idea, or collection of ideas: but, adds he, it is hard to find a discourse on any subject where this is the case; a practice which can only be imputed to folly, or great dishonesty: since a man, in making up his accompts, might with as much fairness use the numeral characters sometimes for one, sometimes for another collection of unities.

EQUIVOCAL GENERATION, the production of animals without the intercourse between the sexes, by the influence of the sun or stars, &c. The equivocal generation of plants, is their production without seed, in the ordinary course of nature. This kind of generation is now quite exploded by the learned. Mr. Ray is clearly of opinion that there is no such thing as spontaneous or equivocal generation, but that all animals are the issue of parents of the same species with themselves; and with him agree Redi, Willughby, and Lister. This last author has fully refuted the vulgar notion, that horse-hairs thrown into water will become animated bodies; by showing that appearances of this kind are hair-worms bred in the bodies of other insects, and particularly of the common black-beetle.

EQUULEUS, or *ecuuleus*, in antiquity, a kind of rack used for extorting a confession, at first chiefly practised on slaves, but afterwards made use of against the christians. The equuleus was made of wood, having holes at certain distances, with a screw, by which the criminal was stretched to the third, sometimes to the fourth or fifth holes, his arms and legs being fastened on the equuleus with cords; and thus was hoisted aloft, and extended in such a manner that all his bones were dislocated. In this state red-hot plates were applied to his body, and he was goaded in the sides with an instrument called ungula.

EQUULEUS, in astronomy, a constellation of the northern hemisphere, whose stars, according to Ptolemy and Tycho's catalogues, are four, but in Mr. Flamsteed's ten.

EQUUS, the horse, a genus of the mammalia class, of the order of belluæ. The generic character is, front teeth in the upper jaw six, parallel; in the lower jaw six, somewhat projecting; canine teeth, one on each side, in both jaws, remote from the rest; feet with undivided hoofs.

1. Equus caballus, or the common horse, the most noble and interresting of quadrupeds, is supposed to be found in a state of nature in several parts of Asia and Africa. In this state it is smaller than the domestic or tame animal, with a larger head, a more arched forehead, and the body thickly covered with pale-brown, or mouse-coloured hair. It has been affirmed by several authors, that wild horses were to be found in the deserts of Arabia; but we must [agree] with Mons. Sonnini, in thinking it not very probable that this animal should be able to exist in such deserts. We must, therefore, rather suppose that it is occasionally found wild in some parts of the country bordering perhaps on the confines of the desert. It is certain that in Arabia the most beautiful domestic horses are bred; and even those which are kept by the Arabs of the desert are allowed to excel most others in swiftness and elegance of form, and it is from their breed that the European horses have been gradually improved. See plate Nat. LIII. Hist. fig. 182.

Large herds of wild horses are said to be found about the lake Aral, near Kusneck, in lat. 54°; on the river Tom, in the southern parts of Siberia; and in the great Mongalian deserts, and among the Kalkas, north-west of China; and it is affirmed that they will occasionally surround and trepan the horses of the Mongalians and Kalkas, while grazing, and carry them off among their own herd. They are extremely swift, active, and vigilant; and, like some of the antelopes and other quadrupeds, have always a sentinel, who gives notice to the herd on the approach of danger by a loud neigh; upon which they fly off with amazing rapidity.

Wild horses are found, according to Dr. Pallas, in the deserts on each side of the river Don, towards the Palus Mæotis; but these are supposed to be the offspring of the Russian horses, which were employed in the siege of Asoph, in the year 1697, when for want of forage they were turned loose, and their descendants have gradually relapsed into the appearance of natural wildness. Those which are found in some parts of South America, are well known to be the descendants of the horses introduced by the Spaniards on the first discovery of America, and which have so far relapsed into a state of nature as to exhibit the general characters of the wild animal.

The horse, in its domestic or improved state, is found in almost every part of the world, except perhaps within the Arctic circle; and its reduction and conquest may well be considered, as Buffon properly observes, as the greatest acquisition from the animal world ever made by the art and industry of man.

Of the several breeds of horses in common or general use in Europe, it is remarkable that none can come in competition with those of our own island, either for the strength required in laborious services, or for the swiftness and elegance of such as are bred for the course. The

annals of Newmarket record instances of horses that have literally outstripped the wind, as is proved from accurate calculations. The celebrated Childers is commemorated, in particular, as the swiftest of his tribe; and the instances of his speed may be found in various publications. He was known to have run near a mile in a minute; and to have cleared the course at Newmarket, which is only 400 yards short of four miles, in six minutes and forty seconds; running at the rate of eighty-two feet and a half in the space of a second. See Plate LIII. Nat Hist. fig. 183.

Of nearly equal fame is the character of Eclipse, whose strength was said to be greater, and his swiftness scarcely inferior. This latter animal forms the subject of Mons. Sainbel's calculations, who, in his work on the veterinary art, has given an elaborate and curious description of his several proportions. It is remarkable that this horse was never esteemed handsome, though the mechanism of his frame, so far as regarded his powers of swiftness, was almost perfect.

As it may be some satisfaction to the reader, to be made acquainted with the general proportions of this extraordinary courser, we shall here extract a part of Mons. Sainbel's observations on the subject.

"The horses of different countries are, in general, distinguished from each other by a peculiar and appropriate conformation. The Spanish horse differs materially in his outward appearance from the English race-horse. The difference, in the length and direction of the parts of which each is composed, produces in each a system from whose mechanical arrangement result motions very unequal in their extent. The Spanish horse cadences his steps with dignity, while the English horse drives his mass forward with strength and speed. This difference, which proceeds from the peculiar conformation of each, contradicts, in some particulars, the table of geometrical proportions in the use of the pupils of the veterinary schools of France. It proves that no common measure can be made to apply equally to every species, since nature has even diversified the forms of the individuals which compose it. If each species has its own style of beauty; if even each individual has its peculiar beauty; if it is not possible to find two horses that perfectly resemble each other; we cannot pretend to assign any one form preferable to another as the rule of beauty for the horse. Were persons the best qualified to endeavour to collect together the different beauties dispersed among the different individuals, they might indeed compose a model of each species sufficiently perfect to direct the painter or the statuary, but would deceive any one who would venture to choose a horse by it for his own use. The following observations do not take for their object those forms which please the eye at the first glance; that appearance which vulgarly passes for handsome; but that mechanical construction of the animal, from which result the possibility and extent of those motions by the means of which he is enabled to transport himself from one place to another with greater or less speed; and consequently a horse may appear ugly to a vulgar eye, and be still well proportioned. Eclipse was never esteemed handsome; yet he was swift, and the mechanism of his frame almost perfect. Whoever compares his proportions with those in the table above-mentioned, will discover the following differences.

"1. In that table the horse should measure three heads in height, counting from the foretop to the ground. Eclipse measured upwards of three heads and a half.

"2. The neck should measure but one head in length: that of Eclipse measured a head and a half.

"3. The height of the body should be equal to its length: the height of Eclipse exceeded his length by about one-tenth.

"4. A perpendicular line falling from the stifle should touch the toe: this line in Eclipse touched the ground at the distance of half a head before the toe.

"5. The distance from the elbow to the bend of the knee should be the same as from the bend of the knee to the ground: these two distances were unequal in Eclipse, the former being two parts of a head longer than the latter.

"This summary comparison shows that the beauty of a horse cannot be absolutely determined by general rules, but must ever be in relation to a particular species."

Mons. Sainbel farther informs us, that "on the 25th of February, 1789, Eclipse was seized with a violent cholic. The remedies acknowledged as most proper in that case were administered, but without effect. He expired on the 27th, at seven o'clock in the evening, in the 26th year of his age."

In Mons. Sonnini's edition of Buffon may be found an exact enumeration of all the different colours of which horses are seen, with their several shades and names. On this subject also Gesner and Aldrovandus have given the usual enumerations; in general, however, it seems agreed, that the colour is one of the least important attributes; according to the well-known doctrine, now passed into a proverb, that a good horse is never of a bad colour. The ancients appear to have had a predilection for white horses, which were used to draw the cars of emperors and conquerors in public processions. The poets also represent the steeds of many of their heroes as of a snow-white colour. It is remarkable, however, that Virgil, though in the Æneid he represents the horses of Turnus as white, yet in his Georgics condemns that colour. In reality, however, as the learned Dr. Martyn has well observed, this implies no contradiction; since Virgil might be supposed to admire the beauty of a white steed, though he could not commend the colour in a breed or stock. But no country has produced a breed of horses equal in size and strength to the larger kind of our draught-horses. The cavalry of England is, in general, formed of this class of horses. The fens of Lincolnshire generally produce a larger breed than any other part of the kingdom. See Plate LIII. Nat. Hist. fig. 184. In our own country there seem to be no breeds of horses naturally of a perfect white; those which are so termed having been first grey, changed through age to whiteness.

The most beautiful general colour seems to be bright bay, which gives an air of peculiar neatness and elegance to the animal. Black horses are commonly of large size, and in this country are chiefly used for the cart and the plough. In some countries horses are not less esteemed for being variegated or piebald, as it is commonly termed. This is said to be the case in China.

Mr. Bruce informs us, that the horses of Nubia are of unparalled beauty; far superior, in his opinion, even to those of Arabia. He observes, however, that from the manner in which they are fed they are apt to become too fat or corpulent.

In some parts of India is found a remarkable diminutive race of horses, scarcely exceeding the size of a large dog. Small breeds of horses also occur in some of the northern parts of the world.

2. Equus hemionus, or jicta. This is a species, the knowledge of which seems to have lain dormant almost since the days of Aristotle, till it was revived by the observations of Dr. Pallas, who describes it under the title of equus hemionus, supposing it to be the hemionos of Aristotle. It is a native of the wild or desert regions between the rivers Onon and Argun, in the most southern parts of Siberia; and extends over the vast plains and deserts of Tartary, as well as that of Gobi, which reaches even to India. In Tartary it is said to be most frequent about the salt lake called Tarienoor, which is at times dried up. It shuns wooded and mountainous regions, and is said to live in small herds of about twenty each. Its general manners are those of the common wild horse; but its swiftness is still greater, surpassing even that of the antelopes, and is proverbial in some of the regions it frequents; and the Thibetians represent Chammo, their god of fire, mounted upon it.

This animal has an appearance much resembling that of a common mule; having a large head, flat forehead, middle-sized eyes with ash-coloured irides: their teeth are thirty-eight in all, being two in number fewer than in the common horse: the ears are larger than in that species, erect, and lined with a thick, whitish, curling hair: the neck is slender and compressed: the mane upright, short, soft, and of a greyish colour. In place of the foretop there is a short tuft of downy hair, about two inches in length. The body is rather long, and the back but little elevated, the breast sharp and protuberant; the limbs long and elegant; the thighs thin, as in a mule; within the fore legs is an oval callus, but none in the hind legs: the hoofs are oblong, smooth, and black: the tail like that of a cow, being slender, and naked for half its length; the remainder covered with long ash-coloured hair. The winter coat of this animal is of a brownish ash-colour, with the tips of the hair grey; it is about two inches long, and soft like that of a camel; slightly waved or undulated on the back. In summer it becomes much smoother, and in all parts elegantly marked by small featherings or turnings: the tip of the nose is white; and the remainder of the face of a light tawny cast, which is also diffused over all the upper parts: the hind thighs, insides of the limbs and belly, are white; and from the mane to the tail extends a chesnut or blackish-brown line, which is broadest on the lines, and gradually lessens as it approaches the tail: there is also a very slight appearance of a transverse band or cross over the shoulders. The length of this species, from nose to tail, is about six feet and a half; that of the trunk of the tail sixteen inches, and of the hairs beyond the tip about four inches: the height about three feet nine inches.

This species is supposed to have been found in Syria, and some other regions, in the days of Aristotle; and is mentioned by Pliny, from the report of Theophrastus, as being found in Cappadocia. Its native name among the Mongalians is dschikketai, and among the Chinese yo-to-tse.

3. Equus asinus, the ass. The ass, having been long condemned to a state of the lowest servitude, and considered as a species of less dignity than the horse, has acquired in most parts of Europe, a character of contempt. Yet in its natural or wild state it exhibits an appearance very far superior both in point of beauty and vivacity. It is a native of many parts of Asia, living, like the rest of this genus, in a gregarious manner. It chiefly occurs in the dry and mountainous deserts of Tartary, and in the southern parts of India and Persia. It is also said to be found in Africa, and to occur, though but very rarely, in some parts of Syria and Arabia; countries where it was in ancient times extremely common. In this its natural state its colour is said to be white, or of a very pale silvery grey, with a slight tinge of straw-colour on the sides of the neck and body: along the back runs a deep-brown stripe of thickish wavy hair, to the beginning of the tail: this stripe is crossed over the shoulders, as in the tame animal, by another of similar colour; but it is said that this is peculiar to the male. The neck is furnished with a brown mane three or four inches long, consisting of soft woolly hair: the tail is tufted at the end by dusky hairs of about six inches in length: the forehead is arched, and the ears erect, pointed, and lined internally with white curling hairs. It stands higher on its limbs than the domesticated animal, and its legs are more slender in proportion. The hair on the whole body is very fine, bright, soft, and silky; and on some parts marked by a few obscure waves or undulations of a darker shade than the rest. Those which are found in Africa are said to be of a pale ash-colour, rather than of the cast above described.

The food of the wild ass consists chiefly of saline, or bitter and lactascent plants. It is also fond of salt or brackish water. The manners of these animals very much resemble those of the wild horse. They assemble in troops, under the conduct of a leader or sentinel; and are extremely shy and vigilant, and, like the former animals, dart on with the utmost rapidity on the sight of mankind. They have been at all times celebrated for their swiftness. Their voice resembles that of the common or domesticated ass, but is somewhat shriller.

From this animal the domestic ass has been gradually derived, which admits of considerable varieties as to size, beauty, and strength, in different countries. Those of the eastern parts of the world, as well as those of Africa, still partake, in a great degree, of the native elegance of their original or stock; and are very different from those commonly seen in the northern parts of Europe: for this animal seems to be much injured by the influence of a comparatively cold climate. See Plate LIII. Nat. Hist. fig. 185.

The generality of European asses have large slouching ears, a heavy appearance, and are of an ash-colour, more or less deep in different individuals, with a blackish dorsal stripe, crossed by another over the shoulders, and thus exhibiting the original mark of their species. In their manners they exhibit no superior marks of sagacity, but have the merit of being patient, quiet, and

tractable, and are chiefly employed in the inferior offices of servitude. The ass is observed to be very temperate in his food, and by no means delicate in the choice of it; eating thistles, and a variety of coarse herbage which the horse refuses. He is said to be particularly fond of plantain, for which he will neglect every other herb of the pasture. In his choice of water he is remarkably nice, and will drink only of that which is clear. He has also an aversion to mud or water in his road, and will pass out of the way rather than wet his feet in a puddle. He is by no means void of docility, as vulgarly supposed; but may be made to practise several exercises not usual with his race. His voice, as is well known, is a most hideous bray; a discordant succession of flats and sharps. This is most strong in the male animal; the voice of the female being weaker, though somewhat shriller. It is singular, however, that some authors have denied that the female ass can properly be said to bray; and Aldrovandus censures Ovid for this line:

Et rudit e scabra turpis asella mola.

It may not be improper to observe, that the mule is nothing more than a hybrid animal, between this species and the horse, differing in strength, size, and beauty, according to the predominancy of its parental species. Mules are very little used in this country, but in Spain and some other parts of Europe are in much esteem, and have deservedly the reputation of being remarkably sure-footed.

4. Equus zebra, or the zebra, is a native of the hotter parts of Africa, being found from Æthiopia to the Cape of Good Hope, living in large herds, and possessing much of the manners both of the wild horse and the ass, being excessively swift and vigilant. It is of a still wilder or more unmanageable disposition than either of the former animals, and even such as have been taken very young are with much difficulty brought to any degree of familiarity, and have very rarely been rendered so far manageable as to submit to the bridle.

The size of the zebra is equal, or rather superior, to that of the ass, and its form more elegant; since, exclusive of its beautiful colour, the head and ears are well shaped, and of moderate size. The colour is either milk-white, or cream-colour, with a very slight cast of buff or pale ferruginous; and the whole animal is decorated on every part with very numerous black or blackish-brown stripes, disposed with the utmost symmetry, and exhibiting an appearance not so easily described in words as by a well-conducted figure. These stripes run in a transverse direction both on the body and limbs, and in a longitudinal direction down the face; and their regular and beautiful gradation, flexures, and termination on the different parts of the animal, cannot be viewed without admiration. The tail is of a moderate length, round, rather slender, marked with small blackish bars, and terminated by a thickish tuft of brown or black hair. The zebra seems to have been unknown to the ancients; the onager of Pliny and other authors relating only to the wild ass.

Attempts have been made to domesticate the zebra, and to reduce it to obedience, like the horse; but as yet the success has not been very considerable. Experiments of this kind have been chiefly made in Holland; and we are told by the count de Buffon, that zebra's have been yoked to the stadtholder's chariot: this, however, proved to be a piece of misinformation, and is accordingly contradicted in the sixth supplemental volume. Persevering attention may perhaps at length reduce this beautiful animal to a state of domesticity. If this was practicable, a new and elegant addition would be made to the luxuries of civilized life; since the zebra scarcely yields to the horse in gracefulness of figure, exclusive of its captivating colours. See Plate LIII. Nat. Hist. fig. 186.

5. Equus quagga, or the quagga, which till lately had been confounded with the zebra, is now acknowledged as a distinct species, much allied to the former, but marked with fewer and larger bands, which are of a browner colour than in the zebra, and are chiefly disposed on the fore parts of the animal, while the hind parts are rather spotted than striped. The ground-colour also of the quagga is of a ferruginous tinge, especially on the thighs and back. It is of a milder or more docile nature than the zebra, and is said to have been successfully used by some of the Dutch colonists at the Cape, in the manner of a horse, for draught, &c. It inhabits the same parts of Africa as the zebra, but is found in separate herds, never associating with that species. See Plate LIII. Nat. Hist. fig. 187.

6. Equus bisculus, or cloven-footed horse. The very name of this species seems to imply a kind of equivocal and anomalous being; one of the most prominent characters of the present genus being a simple or undivided hoof. Indeed if only a single specimen of this animal had been described, we might have hesitated as to admitting it otherwise than as an accidental variety.

The cloven-footed horse is a native of South America, and was first described by Molina, in his Natural History of Chili. In its general appearance, size, colour, and many other particulars, both external and internal, it resembles the ass; but has the voice and the ears of a horse, and has no cross or transverse band over the shoulders. It is very wild, strong, and swift, and is found in the rocky regions of the Andes or Cordilleras of Peru and Chili. The hoofs are divided like those of ruminant animals.

It is singular that this curious species, which seems to form a kind of link between the cloven-hoofed and whole-hoofed tribes, should have so long remained unknown to the naturalists of Europe.

ERANARCHA, a public officer among the ancient Greeks, whose business was to preside over and direct the alms and provisions made for the poor. Cornelius Nepos, in his life of Epaminondas, describes his office thus: when any person was reduced to poverty, taken captive, or had a daughter to marry, which he could not effect for want of money, &c. the eranarcha called an assembly of friends and neighbours, and taxed each according to his means and estate, to contribute towards his relief.

ERANTHEMUM, a genus of the monogynia order, in the diandria class of plants, and in the natural method ranking with those of which the order is doubtful. The corolla is quinquefid, with the tube filiform; the antheræ without the tube; the stigma simple.

There are five species, herbs or undershrubs of the Cape of Good Hope. Some of them are very ornamen-

tal inhabitants of our stoves, and would probably thrive in a greenhouse.

ERICA, *heath*, a genus of the monogynia order, in the octandria class of plants, and in the natural method ranking under the 18th order, bicornes. The calyx is tetraphyllous; the corolla quadrifid; the filaments inserted into the receptacle; the antheræ bifid; the capsule quadrilocular. There are upwards of 100 species, four of them natives of Britain, which are so well known, that no description need be given of them. In the Highlands of Scotland this plant is made subservient to a great variety of purposes. The poorer inhabitants make walls for their cottages with alternate layers of heath and a kind of mortar made of black earth and straw. The woody roots of the heath are placed in the centre; the tops externally and internally. They make their beds of it, by placing the roots downwards; and the tops only being uppermost, they are sufficiently soft to sleep upon. Cabins are also thatched with it. In the island of Ilay, ale is frequently made by brewing one part of malt and two of the tops of young heath, sometimes adding hops. Boethius relates, that this liquor was much used by the Picts. Woollen cloth boiled in alum-water, and afterwards in a strong decoction of heath-tops, comes out of a fine orange-colour. The stalks and tops will tan leather. Besoms, and faggots to burn in ovens, are also made of this plant. It is also used for filling up drains that are to be covered over. Sheep and goats will sometimes eat the tender shoots, but they are not fond of them. Cattle not accustomed to feed on heath, give bloody milk, but they are soon relieved by drinking plentifully of water. Horses will eat the tops. Bees extract a great deal of honey from the flowers; and where heath abounds, the honey has a reddish cast. There are many exotic species with which our greenhouse collections are enriched and adorned, as the triflora, tubiflora, australis, &c.

ERIDANUS, in astronomy, a constellation of the southern hemisphere, containing, according to different authors, 19, 30, or even 84 stars.

ERIGERON, *flea-bane*, a genus of the polygamia superflua order, in the syngenesia class of plants, and in the natural method ranking under the 49th order, compositæ. The receptacle is naked; the pappus hairy; the florets of the radius are linear, and very narrow. There are 30 species, of which the most remarkable is the viscosum, or male flea-bane of Theophrastus, and greater flea-bane of Dioscorides. It is a native of the south of France and Italy; and has a perennial root, whence arise many upright stalks near three feet high. The leaves in warm weather sweat out a clammy juice; the flowers are produced single upon pretty long footstalks, are of a yellow colour, and have an agreeable odour. The plants are easily propagated by seeds, and thrive best in a dry soil and sunny aspect.

ERINUS, a genus of the angiospermia order, in the didynamia class of plants, and in the natural method ranking under the 40th order, personatæ. The calyx is pentaphyllous; the limb of the corolla quinquefid and equal, with its lobes emarginated, and the upper lip very short and reflexed; the capsule bilocular. There are 13 species. They grow from two inches to four feet in height, and are adorned with flowers of a white or purple colour. They are propagated by seeds, but in this country generally require to be kept in shelter.

ERIOCAULON, a genus of the trigynia order, in the triandria class of plants, and in the natural method ranking with the sixth order, ensatæ. The common calyx is an imbricated capitulum or knob; there are three equal petals, and the stamina are on the germen. There are six species, exotics of no note.

ERIOCEPHALUS, a genus of the polygamia necessaria order, in the syngenesia class of plants, and in the natural method ranking under the 49th order, compositæ. The receptacle is somewhat villous; there is no pappus; the calyx is decaphyllous and equal: the radius has five florets. There are two species, herbaceous plants of the Cape.

ERIOPHORUM, a genus of the monogynia order, in the triandria class of plants, and in the natural method ranking under the third order, calamariæ. The glumes are paleaceous, and imbricated all round; there is no corolla; and only one seed furnished with a very long down. There are six species, nearly allied to the grasses, only two natives of Britain.

ERITHALIS, a genus of the monogynia order, in the pentandria class of plants, and in the natural method ranking with those of which the order is doubtful. The corolla is quinquepartite; the calyx urceolated or bladder-like; the berry decemlocular, inferior. There are two species, trees of Jamaica and the Society Isles.

ERINACEUS, *hedgehog*, a genus of quadrupeds of the order of feræ. The generic character is; front teeth two both above and below, those of the upper jaw distant, of the lower approximated; canine teeth on each side, in the upper jaw five, in the lower three; grinders on each side, both above and below, four; body covered on the upper parts with spines.

1. Erinaceus Europæus. Common or European hedgehog. The hedgehog is found in most of the temperate parts of Europe and Asia, and, according to Mr. Pennant, is also seen in Madagascar. It commonly measures about 11 inches from the nose to the tip of the tail, which is about an inch long. Its colour is generally grey-brown, but it sometimes is found totally white, or of a yellowish white. It feeds principally on the roots of vegetables; but it also eats worms, as well as beetles and other insects. It wanders about chiefly by night, and during the day conceals itself in its hole, under the roots of some tree, or mossy bank. It produces four or five young at a birth, which are soon covered with prickles like those of the parent animal, but shorter and weaker. The nest is large, and is composed of moss.

The hedgehog, when disturbed, rolls itself up into a globular form, and thus presents to its adversary an invulnerable ball of prickles. From this state of security, it is not easily forced; scarcely any thing but cold water obliging it to unfold itself. It swims perfectly well when thrown into water.

The hedgehog is one of those animals which, during the winter, are supposed to continue in a state of torpidity. In that season it lies concealed in its hole, surrounded with a bed of moss, secure from the rigours of the most piercing frost, and at the return of spring recommences its wanderings.

The hedgehog may be rendered in a considerable degree domestic; and has frequently been introduced into houses for the purpose of expelling those troublesome insects the blattæ, or cockroaches, which it pursues with avidity, and is fond of feeding on. It is itself an occasional article of food in some places, and is said to be best in the month of August.

The hedgehog is generally considered as a harmless inoffensive animal, but has been frequently supposed (and to this day the absurb notion prevails in many places) to suck the teats of cows by night, and thus cause by its prickles those exulcerations which are sometimes seen on cattle. From this accusation, however, it is completely absolved by Mr. Pennant, who observes, that its mouth is by far too small to admit of this practice.

2. Erinaceus inauris. Earless hedgehog. This, on a general view, seems to be nothing more than a variety of the common hedgehog, differing chiefly, according to Seba, in having the spines on the upper parts of the body shorter, thicker, and stronger; the head, however, is somewhat shorter, and the snout blunter than in the common hedgehog, and there is no appearance of external ears; the whole animal is also of a white or very pale colour. Its length from nose to tail is about eight inches; the tail scarcely an inch long; the claws long and crooked.

3. Erinaceus auritus. Long-eared hedgehog. This species resembles the common hedgehog in form, and is found about the river Volga, and in the eastern parts beyond lake Baikal. In size it is said to vary, being in some places smaller, and in others larger, than the common species; but may be immediately distinguished by its ears, which are large, oval, open, and naked, with soft whitish hair on the inside, and edged with brown; the legs and feet are longer and thinner than those of the common hedgehog, and the tail shorter and almost naked; the upper part of the animal is covered with slender brown spines, with a whitish ring near the base, and another towards the tip; the legs and belly are covered with soft white fur. In its general manner of life this species is said to resemble the common hedgehog. The female produces six or seven young at a time, and is said sometimes to breed twice a year.

4. Erinaceus Madagascariensis. Striped hedgehog. This animal, which is a native of Madagascar, was first described by the count de Buffon, under the name of le tanrec; it should seem, however, that the specimen described had not attained its full growth, and consequently did not exhibit with sufficient clearness all the characters of the animal. It is of a black colour, with five longitudinal bands on the body; all the black parts are covered with hard hair; the white bands with small prickles, analogous to those of a porcupine. From the black bands on the back, spring long scattered hairs which reach to the ground; the head is covered with short black hairs or prickles; the snout is white; the eye surrounded by a white circle, and the feet are reddish. The tandreks move slowly, and grunt like pigs, for which reason they are called ground-hogs, or pig-porcupines, by the Europeans. They burrow under ground, and remain torpid three months in the year; they hide themselves in the day-time, and only appear after sunset in order to seek their food: they live chiefly on fruits and herbs; their body is a mere lump of fat: the natives of Madagascar eat them, but consider them as but an indifferent food. Madagascar is the only country in which the tandreks are found. See Plate LV. Nat. Hist. fig. 188.

5. Erinaceus Malaccensis. Malacca hedgehog. This species has so completely the appearance of a porcupine, that nothing but a severe adherence to systematic arrangement from the teeth could justify its being placed in the present genus; yet even this particular seems not yet distinctly known, the animal being rarely imported into Europe. Mr. Pennant supposes that Linnæus might have been induced to consider it as belonging to the present genus, on account of the number of its toes; which are said to be five on the fore feet, instead of four, as in the porcupine. The accurate Brisson, however, considered it as a species of hedgehog; and Linnæus, in compliance with his opinion, transferred it from the genus hystrix to that of erinaceus. The particular size is not mentioned by Seba, but it appears to be a large species, since the length of its quills is said to be from an inch to a foot and a half, on different parts of the animal. It is therefore probably about the size of the common porcupine, and they are variegated in a similar manner; the ears are large and pendulous; and there is no crest or ruff of longer bristles than the rest on the back of the head, as in the common porcupine.

ERMIN. See Mustela.

Ermin, in heraldry, is always argent and sable, that is, a white field, or fur, with black spots. These spots are not of any determinate number, but may be more or less, at the pleasure of the painter, as the skins are thought not to be naturally so spotted; but serving for lining the garments of great persons, the furriers were wont, in order to add to their beauty, to sow bits of the black tails of the creatures that produced them, upon the white of their skin, to render them the more conspicuous, which alteration was introduced into armory.

Ermin, or *ears of corn*, an order of knights in France, instituted by Francis, the last of that name, duke of Britany.

This order was so called on account that the collar of it was made up of ears of corn, lying athwart one another in saltier, bound together, both above and below, each ear being crossed twice, the whole of gold. To this collar there hung a little white beast, called an ermin, running over a bank of grass, diversified with flowers.

ERMINE', or Cross Ermine', is one composed of four ermine spots. It is to be observed, that the colours in these arms are not to be expressed, because neither this cross nor these arms can be of any other colour than white and black.

Ermines are, by some English writers, held to be the reverse of ermine', that is, white spots on a black field; and yet the French use no such word, but call this black powdered with white contre-ermin, which is very proper, as it denotes the reverse of ermin.

ERMINITES should signify little ermines, but it is otherwise, for it expresses a white field powdered with black, only that every such spot has a little red hair on it.

ERNODIA, a genus of the class and order tetrandria monogynia. The calyx is four-parted; corolla one-petal-

led, salver-shaped; berry two-celled; seeds solitary. There is one species, a creeping plant of Jamaica.

ERODIUM, *crane's bill*, a genus of the class and order monadelphia pentandria, and in the natural method of the order gruinales. The calyx is five-parted; the corolla five-petalled; nens five scales, alternate with the filaments, and glands at the base of the stamina; fruit five-grained, with a spiral beak, bearded in the inside. This genus is vulgarly confounded with the geranium: indeed there are three genera, which have the same habits, but differing in the number of stamina. This plant has five, the geranium seven, and the pelasconium, or African geranium, ten. Of the erodium there are 28 species, including at least three which are natives of Britain, and several naturalized here: some are annual, and some perennial.

ERODIUS, a genus of insects of the order of coleoptera. The antennæ are moniliform; feelers filiform; body roundish, gibbous, immarginate; thorax transverse; shells closely united, longer than the abdomen; jaw horny, bifid; lip horny, emarginate. There are four species.

EROTEUM, a genus of the class and order pentandria monogynia. The calyx is five-leaved; the corolla five-petalled; the style trifid; berry juiceless, three-celled, many-seeded. There are two species, natives of Jamaica.

ERRHINES, in pharmacy, medicines which, when snuffed up the nose, promote a discharge of mucus from that part. See MATERIA MEDICA.

ERROR, in law, signifies an error in pleading, or in the process; and the writ which is brought for remedy thereof, is called a writ of error. A writ of error is a commission to judges of a superior court, by which they are authorized to examine the record upon which a judgment was given in an inferior court, and on such examination, to affirm or reverse the same according to law. Jenk. Rep. 25. For particulars as to the practice of writs of error, see Impey's K. B. & C. P.

ERUCA, in general, denotes caterpillars of all kinds. The caterpillar state is that through which every butterfly must pass before it arrives at its perfection and beauty: and in the same manner, all the known winged animals, except only the puceron, pass through a reptile state; none of them, except this, being produced in their winged form. The change from caterpillar to butterfly was long esteemed a sort of metamorphosis, a real change of one animal into another; but this is by no means the case. The egg of a butterfly produces a butterfly, with all the lineaments of its parent; only these are not disclosed at first, but for the greater part of the animal's life they are covered with a sort of case or muscular coat, in which are legs for walking: these only suit it in this state; but its mouth takes in nourishment, which is conveyed to the included animal; and after a proper time this covering is thrown off, and the butterfly, which all the while might be discovered in it by an accurate observer with the help of a microscope, appears in its proper form. Before it passes into this state, however, there requires a state of rest for the wings to harden, and the several other parts to acquire their proper firmness: this is transacted in a time of perfect rest, when the animal lies in what is called the nymph or chrysalis state, in appearance only a lump of inanimate matter. There is a settled and determined time for each of these changes in every species; but in the several different kinds, the periods are very different.

There is no sign of sex in the animal while in the caterpillar state: the propagation of the species is the business of the creature in its ultimate perfection; and till that, these parts are never excluded: one female butterfly, when she has been impregnated by the male, will produce 300 or 400 eggs, or even more. There is no way of knowing the sexes of these little creatures by viewing the parts; but the whole figure and manner of the animal makes the difference. The females are always larger than the males; they are also more slow in their motions; and some of them have no wings, or at the most only very small ones. The males also have a sort of beards, more beautiful than the antennæ or horns of the females; the female is much stronger as well as bigger than the male, and not unfrequently, in case of danger or disturbance, she flies away with him in time of copulation. On dissecting the female, her ovarium affords an astonishing sight. The number of eggs in the tubes is amazing; but these have not all the same figure; and in some species, as the silk-worm, &c. the eggs are of a beautiful blue; if any yellowish ones are seen among them, they are judged to be defective.

The care of all the butterfly tribe to lodge their eggs in safety is surprising. Those whose eggs are to be hatched in a few weeks, and who are to live in the caterpillar state during part of the remaining summer, always lay them on the leaves of such plants as will afford a proper nourishment; but, on the contrary, those whose eggs are to remain unhatched till the following spring, always lay them on the branches of trees and shrubs, and usually are careful to select such places as are least exposed to the rigour of the ensuing season, and frequently cover them from it in an artful manner. Some make a general coat of a hairy matter over them, taking the hairs from their own bodies for that purpose; others hide themselves in hollow places in trees, and in other sheltered cells, and there live in a kind of torpid state during the whole winter, that they may deposit their eggs in the succeeding spring, at a time when there will be no severities of wheather for them to combat. The day butterflies only do this, and of these but a very few species; but the night ones, or phalænæ, all, without exception, lay their eggs as soon as they have been in copulation with the male, and die immediately afterwards.

It is well known, that the common and natural food of these creatures is the leaves and verdure of vegetables; yet, as weak and harmless as they seem, they will many of them destroy their fellows whenever they get an opportunity. Mr. Reaumur gives us an instance of this in 20 caterpillars of the oak, which he kept in a box with a sufficient quantity of their natural food; yet their numbers daily decreased, till at last there remained only one. This is, however, only the case in some few species, the generality of these animals being very peaceable, many species living together in the same place without molesting one another. These species, however, though freed from such dangers, are exposed to others of a much more terrible kind; the worms or maggots of se-

veral sorts of flies are frequently found about them, some preying upon their outside, others lodged within them under the skin, but both kinds eating the poor defenceless creature up alive. Those which feed on the outsides are easily discovered: the others are more hidden; and frequently the caterpillar, which seems very hearty and vigorous, and very fleshy, will be found, upon opening, to be a mere skin, the internal parts being found to be all eaten away, and all the food that he swallows serving only to feed a vast number of worms, or maggots, which crawl about at liberty within him. These devouring worms are of many different species; some being of the gregarious, some of the solitary kinds, and some spinning webs of their own silk to transform themselves in, others undergoing that change without any such covering. The beautiful cabbage-caterpillar is one of those unhappy kinds which frequently are infested with the gregarious kinds, large numbers of which spin themselves webs one after another, and afterwards come out in the shape of the parent-fly to whose eggs they owed their origin.

These intestine enemies are a sure prevention of the butterfly's appearing at its proper time; and as many of the former naturalists, who knew what butterfly to expect from a peculiar species of caterpillar which they preserved, often saw a parcel of flies come out in the place of it, they having no idea that the fly had laid its eggs in the flesh of the poor creature, supposed that this was one of its natural transformations, and that certain species of caterpillars sometimes produced butterflies, sometimes small flies. These, and many other destroyers, among which the birds are to be reckoned in the principal place, serve the purpose of preventing the too great number of these mischievous animals. Their usual habitation being the leaves and flowers of plants, they are, in their feeding, much exposed to all those destroyers; yet nature has taken care to preserve a great number, by making many of them so exactly of the colour of the leaves they feed on, that they are not easily distinguished from them; and by giving others a caution of keeping on the under part of the leaves, and being by that means out of sight. But some species are much less exposed, and of much more mischief to the plants they feed on, by devouring more essential parts of them. Of these some eat the roots, and others the interior part of the trunk, destroying the vessels that imbibe, and those that distribute the juices. These are different from the common caterpillars in this, that their skin is much less rough and hard: and these are secure from our observation, and in general from their great destroyers, the birds. They are not, however, absolutely safe from the common dangers of the other species; for there is a kind of worms that find their food and habitation even in the bodies of these. The root-caterpillars, and those which live within the branches of plants, are much more easily found out. The roots of scrophularia, and the stalks of lettuces, and some other plants, afford caterpillars which seem all of the same species. Those found in the lettuces are extremely plentiful some years, and destroy vast quantities of that plant. These usually have their first habitation in the stalk, near the root.

Nothing is more surprising in insects than their industry; and in this the caterpillars yield to no kind, not to mention their silk, the spinning of which is one great proof of it. The sheaths and cases which some of these insects build for passing their transformations under, are by some made with their own hair, mixed with pieces of bark, leaves, and other parts of trees, with paper, and other materials; and the structure of these is well worthy our attention. Yet there are others whose workmanship, in this article, far exceeds these. There is one which builds in wood, and is able to give its case a hardness greater than that of the wood itself in its natural state. This is the strange horned caterpillar of the willow, which is one of those that eat their exuviæ. This creature has extremely sharp teeth, and with these it cuts the wood into a number of small fragments; these fragments it afterwards unites together into a case, of what shape it pleases, by means of a peculiar silk, which is no other than a tough and viscous juice, which hardens as it dries, and is a strong and firm cement. The solidity of the case being thus provided for, we are to consider, that the caterpillar inclosed in it is to become a butterfly; and the wonder is, in what manner a creature of this helpless kind, which has neither legs to dig, nor teeth to gnaw with, is to make its way out of so firm and strong a lodgment as this in which it is hatched. The butterfly, as soon as hatched, discharges a liquor which softens the viscous matter that holds the case together; and so its several fragments falling to pieces, the way out lies open. Reaumur judged, from the effects, that this liquor must be of a singular nature, and very different from the generality of animal fluids; and in dissecting this creature in the caterpillar state, there will always be found near the mouth, and under the œsophagus, a bladder of the size of a small pea, full of a limpid liquor, of a very quick and penetrating smell, and which, upon trial, proves to be a very powerful acid; and among other properties, which it has in common with other acids, it sensibly softens the glue of the case, on a common application. It is evident that this liquor, besides its use to the caterpillar, remains with it in the chrysalis state, and is what gives it a power of dissolving the structure of the case, and making its way through in a proper manner at the necessary time. Boerhaave adopted the opinion, that there are no true acids in animals, except in the stomach or intestines; but this familiar instance proves the contrary.

Another very curious and mysterious artifice is that by which some species of caterpillars, when the time of their changing into the chrysalis state is coming on, make themselves lodgments in the leaves of the trees, by rolling them up in such a manner as to make themselves a sort of hollow cylindric case, proportioned to the thickness of their body, well defended against the injuries of the air, and carefully secured for their state of tranquility. Besides these caterpillars, which in this manner roll up the leaves of plants, there are other species which only bend them once, and others, which by means of thin threads, connect many leaves together to make them a case. All this is a very surprising work, but much inferior to this method of rolling. The different species of caterpillars have different inclinations, not only in their spinning and their choice of food, but even in their manners and behaviour one to another. Some never part company from the time of their being

hatched to their last change, but live and feed together, and undergo together their change into the chrysalis state. Others separate one from another as soon as able to crawl about, and each seeks its fortune single; and there are others which regularly live to a certain time of their lives in community, and then separate, each to shift for itself, and never to meet in that state.

Caterpillars are very destructive to gardens, particularly those of two species. The one, that which afterwards becomes the common white butterfly. This is of a yellowish-white colour, spotted with black, and infests the leaves of cabbages, cauliflowers, and the Indian cress, of which it eats off all the tender parts, leaving only the fibres entire; so that whole plantations are often seen destroyed by them in autumn, especially such as are near large buildings, or are crowded with trees. There is no remedy against this evil but the pulling the creatures off before they are spread from their nests, and watching the butterflies, which are daily, in the hot weather, depositing their eggs on these plants. These, however, feed principally on the outside of the leaves of the plants, and are therefore the easier taken off; but the other kind lies near the centre, and therefore is with much more difficulty discovered. This is much larger; and the skin is very tough, and of a brown colour. It is called by the gardeners a grub, and is extremely pernicious. The eggs which produce it are usually deposited in the very heart or centre of the plant, particularly in cabbages; and the creature, when formed, and grown to some size, eats its way through all the blades, and leaves its dung in great quantities behind it, which spoils the cabbage. This insect also burrows under the surface of the ground, and makes sad havoc among young plants, by eating off their tender shanks, and drawing them into its holes. This mischief is chiefly done in the night; but whatever a plant is seen thus destroyed, if the earth is stirred with a finger an inch deep, the creature will be certainly found, and this is the only way of destroying them.

When these animals attack fruit-trees, the best preservative is to boil together a quantity of rue, wormwood, and the common tobacco, of each equal parts, in common water, to make the liquor very strong, and sprinkle it on the leaves and young branches every night and morning, during the time when the fruit is ripening.

Erucæ *acquaticæ*, *water caterpillars*. It may seem incredible, that there is any such thing as a caterpillar whose habitation is under water; but experience and observation prove, that there are such, and that they feed on the water-plants as regularly as the common kinds do on those at land. These are not named at random like many of the aquatic animals of the larger kinds, as the sea-wolf, the sea-horse, &c. which might as well be called any thing else as wolves and horses; but they are properly what they are called, and do not respire in the manner of the fish tribe, but by their stigmata as other caterpillars. M. Reaumur, in his observations, met with two species of these; the one upon the pond-weed, the other upon the lenticula or duck-meat. These are both very industrious animals; but the first being much the largest, its operations are more easily distinguished. This, though truly an aquatic animal, swims but badly, and does not at all love to wet itself. The parent butterfly lays her egg on the leaf of a certain plant; and as soon as the young caterpillar is hatched, it gnaws out a piece of the leaf, of a roundish shape. This it carries to another part of the same leaf, and lays it in such a manner, that there may be a hollow between, in which it may lodge. It then fastens down this piece to the larger leaf with silk of its own spinning, only leaving certain holes at which it can put out its head, and get to gnaw any of the leaves that are near. It easily gets out, though the aperture is naturally small, since a little force from its body bends up the upper leaf and down the lower, both being flexible; and when the creature is out, it has a sort of down that defends it from being wetted, and the natural elasticity of the leaves and of the silk joins the aperture up again, so that no water can get in. The leaves of this kind of plant are also naturally very slippery, and not easily wetted by water. It soon happens that this habitation becomes too small for the animal, in which case it makes just such another; and after that, at times, several others, each being only made fit for it at the size it is then of. The changes of this creature into the chrysalis and butterfly states are in the common method. The butterfly gets out of a chrysalis which was placed on the surface of the water; the lightness of the animal easily sustains it on the water till its wings are dried, and then it leaves that element, never to return to it again.

Erucæ *sylvestres*, wood caterpillars: the name of a sort of caterpillars which do not live, after the manner of others, on leaves of trees or plants, or open to our observation; but under the bark, in the trunk and branches, and in the roots of trees, and sometimes in the body of fruits. These are easily distinguished from those worms and maggots which are found in roots and fruits, and owe their origin to flies of another kind; but are liable to be confounded with a sort of animals, called by M. Reaumur, false or bastard caterpillars, which bear a great resemblance in their figure to real caterpillars, but which have more legs than any of the true ones have, and are finally transformed into four-winged flies, which are not true butterflies.

The butterflies which are the parents of those caterpillars that lie immured in trees or fruits, lay their eggs on the surface; and the young caterpillars, when hatched, eat their way in. What appears something surprising, however, in this is, that there usually is only one caterpillar in a fruit which is large enough to afford food to a great number; and if there are sometimes found two creatures within, one is usually a caterpillar, the other a worm of some other kind. The whole occasion of this is, that the operation of penetrating into the fruit is so difficult to the young animal, that it seldom succeeds in it; and though the butterfly deposits many eggs on each fruit, and these all hatch, yet it is only here and there one on a fruit that can find its way into it.

These creatures when once lodged in their prison, have nothing to do but to eat up the substances which inclose them, leaving the outer hard shell unhurt, which still serves as a case for them. This is a very frequent case in grains of corn, where the farinaceous substance serves as aliment, and the hard outer skin becomes a firm hollow case afterwards for the animal. The farinaceous substance in this case usually proves enough for

the animal in its caterpillar state; but if it does not, the creature has recourse to a very singular expedient: it eats again its own excrement, and finds its now stronger stomach able to separate nourishment from that very matter which had before passed off from its weaker stomach undigested.

Of these species of caterpillars, some go out of their prison in order to change into their chrysalis, and thence into their butterfly state; but the greater number remain there, and pass through all their changes within. These caterpillars, like all the other kinds, have certain flesh-eating worms, whose parents are of the fly-kind, for their terrible enemies and destroyers; and it is not unfrequent, on opening one of these spoiled fruits, instead of the expected caterpillar, to find a fly just ready to come out: this has been produced from the chrysalis of a worm, which had found its way into the fruit, and eaten up the caterpillar, which was the original possessor of the place.

ERUCTATIONS, in medicine, are the effect of flatulent foods, and the crudities thence arising.

ERUPTION, in medicine, a sudden and copious excretion of humours, as pus or blood; it signifies also the same with exanthema, any breaking out; as the pustules of the plague, small-pox, measles, &c. See MEDICINE.

ERVUM, the lentil, a genus of the decandria order, in the diadelphia class of plants, and in the natural method ranking under the 32nd order, papilionaceæ. The calyx is quinquepartite, the length of the corolla. There are six species; of which the most remarkable is the lens, or common lentil. It is cultivated in many parts of England, either as fodder for cattle, or for the seeds, which are frequently used in meagre soups. It is an annual plant, and rises with weak stalks about 18 inches high, with winged leaves composed of several pairs of narrow lobes, terminated by a clasper or tendril, which fastens to any neighbouring plant, and is thereby supported; the flowers come out three or four together, upon short footstalks from the side of the branches. They are small, of a pale purple colour, and are succeeded by short flat pods, containing two or three seeds which are flat, round, and a little convex in the middle. The seeds of this plant are most commonly sown in the month of March, where the land is dry; but in moist ground, the best time is April. The usual quantity of seed allowed for an acre of land is from one bushel and a half to two bushels. If these are sown in drills in the same manner as peas, they will succeed better than when sown broadcast: the drills should be a foot and a half asunder, to allow room for the Dutch hoe to clean the ground between them; for if the weeds are permitted to grow among them, they will get above the lentils and starve them.

There is another sort of lentil also cultivated in this country, under the name of French lentil. It is twice the size of the former, both in plant and seed; and is much better worth cultivation than the other. It should be sown in March, after a single ploughing, in the ground that bore corn the year before. Manure is not absolutely necessary, though it will undoubtedly increase the crop. Its grass is said to be very copious; it may be mowed many times in the year, and affords a healthy as well as an agreeable food to horses, cows, and sheep; the milk of cows fed with it is said to be very copious and good. Long and numerous pods ripen about the beginning of winter, which afford a new kind of legumen, to be eaten as common lentils; when fresh, it makes admirable peas-soup: dry, it is greedily eaten by the poultry. The dried herb is also a good resource for cattle in winter. It grows on any kind of ground.

ERYNGIUM, sea-holly, or eryngo, a genus of the digynia order, in the pentandria class of plants; and in the natural method ranking under the 45th order, umbellatæ. The flowers are collected into a round head, and the receptacle is paleaceous. There are 11 species; most of which are hardy herbaceous perennials, producing erect stalks from one to two or three feet high; with simple, entire, or divided prickly leaves; and the stalks terminated by roundish aggregate heads of quinquepetalous flowers, of white, blue, or purple colours. They all flower mostly in July, and the seeds ripen in September. They are propagated by seeds sown in a bed or border, either in spring or autumn. The plants are to be removed the autumn after they come up, into those places where they are designed to remain. The leaves of one of the species (viz. the maritimum, which grows naturally on the sea-coasts of England and Scotland) are sweetish, with a light aromatic warmth and pungency. The young flowering shoots, eaten like asparagus, are very grateful and nourishing.

ERYSIMUM, hedge-mustard; a genus of the siliquosa order, in the tetradynamia class of plants; and in the natural method ranking under the 39th order, siliquosæ. The siliqua is long, linear, and exactly tetragonal; the calyx close. There are eight species; of which the most remarkable is the officinale, hedge-mustard, or bank-cresses. It grows naturally in Britain under walls, by the sides of highways, and among rubbish. It is warm and acrid to the taste; and, when cultivated, is used as a vernal potherb. Birds are fond of the seeds; sheep and goats eat the herb; cows, horses, and swine, refuse it. The seeds are said to promote expectoration, and excite urine, but they are scarcely ever employed in medicine at present.

ERYSIPELAS, in medicine, an eruption of a fiery or acrid humour, from which no part of the body is exempted, though it chiefly attacks the face. See MEDICINE.

ERYTHRINA, coral-tree; a genus of the decandria order, in the diadelphia class of plants; and in the natural method ranking under the 32d order, papilionaceæ. The calyx is bilabiate, the one lip above, the other below; the vexillum of the corolla is very long, and lanceolated. There are seven species; all of them shrubby flowering exotics for the stove, adorned chiefly with trifoliate or three-lobed leaves, and scarlet spikes of papilionaceous flowers. They are all natives of the warm parts of Africa and America; and must always be kept in pots, which are to remain constantly in stoves in this country. They are propagated by seeds, which are annually imported hither from Africa and America. They are to be sown half an inch deep in pots of light rich earth, which are then to be plunged in a moderate hot-bed; and when the plants are two inches high, they are to be separated into small pots, plunged in the bark-bed, giving them frequent waterings, and as they increase in growth shifting them into larger pots. The inhabitants of Malabar make sheaths of the wood for swords and

knives. They use the same, together with the bark, in washing a sort of garments which they call sarassas; and make of the flowers the confection caryl. The leaves pulverized, and boiled with the mature cocoa-nut, have been deemed useful in venereal complaints. The juice of the leaves, combined with any greasy matter, also cures the itch and some other eruptions.

ERYTHRONIUM, dog's-tooth violet, a genus of the monogynia order, in the hexandria class of plants, and in the natural method ranking under the 11th order, sarmentaceæ. The corolla is hexapetalous and campanulated, with a nectarium of two turbercles adhering to the inner base of every other petal. There is only one species; which, however, admits of several varieties in its flowers, as white, purple, pale red, dark red, crimson, and yellow. The plants are low and herbaceous, with a purple stalk and hexapetalous flowers. All the varieties are hardy and durable; and may be planted in small patches in borders, where they will make a good appearance. They rarely perfect their seeds in this country, but may be propagated by offsets. In Siberia, according to Gmelin, they dry and mix the root of this plant with their soups. It grows there in abundance, and is called by the people of the country bess.

ERYTHROXYLON, a genus of the trigynia order, in the decandria class of plants; and in the natural method ranking with those the order of which is doubtful. The calyx is turbinated; the petals of the corolla have each a nectariferous emarginated scale at the base; the stamina are connected at the base; the fruit is a bilocular plum. There are five species, beautiful shrubs of the West Indies.

ESCALADE, in war, a furious attack of a wall or a rampart; carried on with ladders, to pass the ditch or mount the rampart; without proceeding in form, breaking ground, or carrying on regular works to secure the men. When the troops are prepared to pass the ditch, either with the assistance of boards, hurdles, and fascines, when it is muddy, or with small boats of tin, or baskets covered with skins or oilcloth, when it is deep and filled with water, a party must be placed on the counterscarp, opposite to the landing-place, ready to fire on the garrison if they are alarmed, and oppose the mounting on the rampart. If the ditch is dry, the ladders are fixed in some place farthest distant from the sentry; and as soon as they get upon the rampart, they put themselves in order to receive the enemy; if the sentry is surprised and silently overcome, the detachment hastens to break open the gate, and to let in the rest of the party. If the ditch is wet, the rampart high, and provided with a revêtement, it will be difficult to surprise the town in this way; but if there is no revêtement, the troops may hide themselves along the outside of the rampart till all are over. Since the invention and use of gunpowder, and the walls of cities have been flanked, they are seldom taken by escalade.

ESCALLONIA, a genus of the monogynia order, in the pentandria class of plants. The fruit is bilocular and polyspermous; the petals distant and tongue-shaped; the stigma headed. There are two species, shrubs of the West Indies and South America.

ESCAPE, in law, is where one who is arrested gains his liberty before he is delivered by course of law.

Escapes are either in civil or criminal cases; and in both respects, escapes may be distinguished into voluntary and negligent: voluntary, where it is with the consent of the keeper; negligent where it is for want of due care in him.

In civil cases, after the prisoner has been suffered voluntarily to escape, the sheriff can never after retake him, but must answer for the debt; but the plaintiff may retake him at any time. In the case of a negligent escape, the sheriff, upon fresh pursuit, may retake the prisoner, and the sheriff shall be excused if he has him again before any action brought against himself for the escape.

When a defendant is once in custody in execution, upon a capias ad satisfaciendum, he is to be kept in close and safe custody; and if he is afterwards seen at large, it is an escape, and the plaintiff may have an action thereupon for his whole debt: for though upon arrests, and what is called mesne process (being such as intervenes between the commencement and end of a suit), the sheriff, till the statute 8 and 9 W. c. 27, might have indulged the defendant as he pleased, so that he produced him in court to answer the plaintiff at the return of the writ; yet, upon a taking in execution, he could never give any indulgence; for in that case, confinement is the whole of the debtor's punishment, and of the satisfaction made to the creditor.

A rescue of a prisoner in execution, either in going to gaol, or in gaol, or a breach of prison, will not excuse the sheriff from being guilty of and answering for the escape; for he ought to have sufficient force to keep him, since he may command the power of the county. 3 Black. 415 and 6.

In criminal cases, an escape of a person arrested, by eluding the vigilance of his keeper before he is put in hold, is an offence against public justice, and the party himself is punishable by fine and imprisonment; but the officer permitting such escape, either by negligence or connivance, is much more culpable than the prisoner, who has the natural desire of liberty to plead in his behalf. Officers therefore, who after arrest negligently permit a felon to escape, are also punishable by fine; but voluntary escapes amount to the same kind of offence, and are punishable in the same degree, as the offence of which the prisoner is guilty, and for which he is in custody, whether treason, felony, or trespass; and this whether he was actually committed to gaol, or only under a bare arrest. But the officer cannot be thus punished, till the original delinquent is actually found guilty or convicted by verdict, confession, or outlawry; otherwise, it might happen that the officer should be punished for treason or felony, and the party escaping turn out to be an innocent man. But before the conviction of the principal party, the officer thus neglecting his duty may be fined and imprisoned for a misdemeanor. 4 Black. 129.

If any person shall convey or cause to be conveyed into any gaol, any disguise, instrument, or arms, proper to facilitate the escape of prisoners, attainted or convicted of treason, or felony, although no escape or attempt to escape be made; such person so offending, and convicted, shall be deemed guilty of felony, and be transported for seven years. 16 Geo. II. c. 31.

ESCAPE-WARRANT, a process which issues out against a person, committed in the king's bench or Fleet prisons,

that, without being duly discharged, takes upon him to go at large.

Upon this warrant, which is obtained on oath, a person may be apprehended on a Sunday.

ESCHALOT. See Allium.

ESCHAR, in surgery, the crust or scab occasioned by burns or caustic medicines. See Surgery.

ESCHAROTICS, in pharmacy, medicines which produce eschars. See Eschar.

ESCHEAT, in our law, denotes an obstruction of the course of descent, and a consequent determination of the tenure by some unforeseen contingency; in which case, the land naturally results back, by a kind of reversion, to the original grantor, or lord of the fee. 2 Black. 244.

Escheat happens either for want of heirs of the person last seized, or by his attainder for a crime by him committed; in which latter case, the blood is tainted, stained, or corrupted, and the inheritable quality of it is thereby extinguished.

For want of heirs, is where the tenant dies without any relations on the part of any of his ancestors, or where he dies without any relations of those ancestors, paternal or maternal, from whom his estate descended, or where he dies without any relations of the whole blood. Bastards are also incapable of inheritance; and therefore if there is no other claimant than such illegitimate children, the land shall escheat to the lord: and, as bastards cannot be heirs themselves, so neither can they have any heirs but those of their own bodies; and therefore if a bastard purchases land, and dies seized thereof without issue and intestate, the land shall escheat to the lord of the fee. Aliens also, that is, persons born out of the king's allegiance, are incapable of taking by descent; and unless naturalized, are also incapable of taking by purchase; and therefore, if there are no natural-born subjects to claim, such lands shall in like manner escheat.

By attainder for treason or other felony, the blood of the person attainted is corrupted and stained, and the original donation of the feud is thereby determined, it being always granted to the vassal on the implied condition of his well demeaning himself. In consequence of which corruption and extinction of hereditary blood, the land of all felons would immediately revert to the lord, but that the superior law of forfeiture intervenes, and intercepts it in his passage; in case of treason, for ever: in case of other felony, for only a year and a day; after which time it goes to the lord, in a regular course of escheat. 2 Black. c. 15.

ESCHEATOR, was an ancient officer, so called because his office was properly to look to escheats, wardships, and other casualties belonging to the crown. This office had its chief dependance on the courts of wards, but is now out of date. Co. Lit. 13 b. 4 Inst. 225.

ESCHRAKITES, a sect of Mahometans, who believe that man's sovereign good consists in the contemplation of God. They avoid all manner of vice, and appear always in good humour, despising the sensual paradise of Mahomet. The most able preachers in the royal mosques are of this sect.

ESCLATTE', in heraldry, signifies a thing forcibly broken, or rather a shield that has been broken and shattered with the stroke of a battle-ax.

ESCROW, among lawyers, a deed delivered to a third person, to be the deed of the party making it upon a future condition; that when a certain thing is performed, it shall be delivered to the party to whom it was made, to take effect as the deed of the person first delivering it.

ESCUAGE, in our old customs, a kind of knight's-service, called service of the shield, by which the tenant was bound to follow his lord to the wars at his own charge. It is also used for a sum of money paid to the lord in lieu of such service; or even for a reasonable aid, levied by the lord on his tenants who held by the knight's-service.

ESCULUS, the horse-chesnut. See Æsculus.

ESCURIAL, a palace of the king of Spain, twenty-one miles north-west of Madrid; being one of the largest and most beautiful in the world. It has eleven thousand windows, fourteen thousand doors, one thousand eight hundred pillars, seventeen cloisters or piazzas, and twenty-two courts; with every convenience and ornament that can render a place agreeable in so hot a climate, as an extensive park, groves, fountains, cascades, grottos, &c. It is whimsically constructed in the form of a gridiron, being dedicated to St. Laurence in commemoration of a victory, gained on the anniversary of that saint (who is said to have been broiled to death on a gridiron) in 1557. The apartment which the royal family inhabits is the handle of the instrument. The rest of the building contains offices, a church, a convent (in which are 200 monks), and a library containing 30,000 volumes.

ESCUTCHEON, in heraldry, is derived from the French escusson, and that from the Latin scutum, and signifies the shield whereon coats of arms are represented.

Escutcheon *of pretence*, that on which a man carries his wife's coat of arms; being an heiress, and having issue by her. It is placed over the coat of the husband, who thereby shows forth his pretensions to her lands.

ESNECY, in law, a private prerogative allowed to the eldest coparcener, where an estate is descended to daughters for want of an heir male, to choose first, after the estate of inheritance is divided. It has been also extended to the eldest son and his issue, holding first, this right being jus primogenituræ.

ESOX, pike, a genus of fishes of the order abdominales. The generic character is, head somewhat flattened above, mouth wide; teeth sharp, in the jaws, palate, and tongue; body lengthened; dorsal and anal fin (in most species) placed near the tail, and opposite each other. There are nine species, of which the most remarkable are:

1. Esox lucius, or common pike. To the general history of this fish perhaps little can be added to what Mr. Pennant has already detailed in the third volume of the British Zoology. It is, says that agreeable writer, a native of most of the lakes and smaller rivers in Europe, but the largest are those of Lapland, which are sometimes eight feet in length: they are taken there in great abundance, dried, and exported for sale. The largest specimen of English growth is said by Mr. Pennant to have weighed thirty-five pounds. The head of the pike is very flat; the upper jaw broad, and shorter than the lower, which turns up a little at the end. is marked with minute punctures: the teeth a

sharp, disposed only in front of the upper jaw, but in both sides of the lower, as well as in the roof of the mouth, and often on the tongue: the number, according to Bloch, is not less than seven hundred, without reckoning the farthest of all, or those nearest the throat: it is also to be observed that those which are situated on the jaws are alternately fixed and moveable; the gape is very wide, and the eyes small: the dorsal fin is placed very low on the back, and consists of twenty-one rays; the pectoral of fifteen; the ventral of eleven, and the anal of eighteen; the tail is slightly forked, or rather lunated. The usual colour of this fish is a pale olive-grey, deepest on the back, and marked on the sides by several yellowish spots or patches: the abdomen is white, slightly spotted with black. When in its highest perfection however the colours are frequently more brilliant; the sides being of a bright olive with yellow spots, the back dark green, and the belly silvery. Dr. Bloch assures us that in Holland the pike is sometimes found of an orange-colour, marked with black spots: the scales are rather small, hard, and of an oblong shape.

The voracity of the pike is commemorated by all ichthyological authors. Mr. Pennant observes that he himself has known a pike that was choaked in attempting to swallow one of its own species which proved too large a morsel. It will also devour water-rats, and young ducks which happen to be swimming near it. In a manuscript note to a copy of Plott's History of Staffordshire, the following highly singular anecdote is recorded. "At lord Gower's canal at Trentham, a pike seized the head of a swan as she was feeding under water, and gorged so much of it as killed them both: the servants, perceiving the swan with its head under water for a longer time than usual, took a boat and found both swan and pike dead."

But there are instances, says Mr. Pennant, still more surprising, and which indeed border a little on the marvellous. Gesner relates that a famished pike in the Rhone, seized on the lips of a mule that was brought to water, and that the beast drew the fish out before it could disengage itself: he adds that people have been bitten by these voracious animals while they were washing their legs, and that they will even contend with the otter for its prey, and endeavour to force it out of its mouth.

The smaller kind of fishes are said to show the same uneasiness and detestation at the presence of a pike as the smaller birds do at the sight of a hawk or an owl, and when the pike, as is often the case, lies dormant near the surface of the water, are observed to swim round in vast numbers, and in the greatest anxiety. In the ditches near the Thames pike are often haltered in a noose, and taken while they lie thus asleep, as they are frequently found in the month of May.

The longevity of the pike is very remarkable; if, as Mr. Pennant observes, we may credit the accounts given by authors. Rzaczynski in his Natural History of Poland tells us of one that was ninety years old; but Gesner relates that in the year 1497, a pike was taken near Haliburn, in Suabia, with a brazen ring affixed to it, on which were these words in Greek characters "I am the fish which was first of all put into this lake by the hands of the governor of the universe Frederic the Second, the fifth of October 1230;" so that, adds Mr. Pennant, the former must have been an infant to this Methusalem of a fish.

The pike spawns in March and April, according to the warmth or coldness of the season; depositing its ova among the weeds, &c. near the water's edge: the young are said to be of very quick growth: indeed Bloch considers it as the quickest grower of all the European fishes whose progress he has had an opportunity of observing. The first year, according to this author, it arrives at the length of from six to ten inches; the second to twelve or fourteen; and the third to eighteen or twenty. The stomach of the pike is strong and muscular, and of very considerable length: it is also furnished with several large and red pleats: in the intestinal canal have been observed several kinds of worms and particularly tænia, of which no fewer than a hundred have been seen in a single fish.

2. Esox sphyræna, or sea-pike. This species in its general habit or appearance is considerably allied to the common pike, but is of a silvery blueish colour, dusky on the back, and slightly tinged with yellow on the head and about the gills: the first dorsal fin is situated on the middle of the back, and is furnished with only four rays, which are all strong or spiny: the second, which is placed opposite the anal fin, consists of about ten rays, of which the first only is spiny: both these dorsal fins, together with the tail, which is deeply forked, are of a dusky tinge; the pectoral, ventral, and anal, are of a pale red: the eyes are moderately large: the lower jaw longer than the upper; the scales middle-sized, and the lateral line nearly straight. This fish is an inhabitant of the Mediterranean and Atlantic seas, growing to the length of about two feet. It is said to be in considerable esteem for the table, the flesh resembling that of the cod-fish.

3. Esox barracuda, or barracuda pike, has the habit of the common pike, but is of a longer form, and more slender or taper in proportion towards the tail: size very great, some having been seen of ten feet in length; but the more common size is from six to eight feet. This is said to be an extremely strong, fierce, and dangerous fish, swimming with great rapidity, and preying on most others: it is even said sometimes to attack and destroy bathers, in the same manner as the shark. It is found in great plenty in the tropical seas, and is frequent about the West Indian islands. It is in no estimation as a food, the flesh being rank; and even sometimes, according to common report, highly noxious, occasioning all the symptoms of the most fatal poisons; yet, in spite of these bad qualities, we are assured that the hungry Bahamians frequently make their repast "on its unwholesome carcase."

4. Esox vulpes, or the fox pike. Its general length is about sixteen inches: habit somewhat similar to that of a common pike, but remarkably slender or taper towards the tail, which is very deeply and widely forked; mouth of moderate width: jaws equal, and with a single row of sharp teeth in each: dorsal fin situated in the middle of the back: scales rather large, thin, and rounded: colour of the whole fish brown, paler or lighter beneath: native of Carolina and the West Indian islands.

5. Esox malabaricus, or Malabar pike, is in length about twelve inches; habit distantly allied to that of the

common pike, but with the tail rounded, and the dorsal fin placed on the middle of the back: colour yellowish; dusky on the back; lower jaw longer than the upper; eyes rather large; scales large, and very distinct; the lateral line bending a little downwards at its origin from the gill-covers, and then running straight to the tail; all the fins, together with the tail, of a very pale transparent brown, barred by several rows of deep-brown spots. Native of Malabar, inhabiting rivers and rivulets, and in considerable esteem for the table.

6. Esox bellone, gar fish, or sea-needle, is well known by its protracted snout, and the bones, which are green when boiled.

ESPALIERS, in gardening, are rows of trees planted about a whole garden or plantation, or in hedges, so as to inclose quarters or separate parts of a garden; and are trained up regularly to a lattice of wood-work in a close hedge, for the defence of tender plants against the injuries of wind and weather.

ESPLANADE, in fortification, the sloping of the parapet of the covered way towards the campaign. It is the same with glacis, and is more properly the empty space betwixt a citadel and the houses of a town, commonly called a place of arms. See FORTIFICATION.

ESPLEES, in law, the general products which lands yield, or the profit or commodity that is to be taken or made of a thing; as of a common, the taking of grass by the mouths of the beasts that common there; of an advowson, taking of tythes by the parson; of wood, the selling of wood; of an orchard, selling the fruit growing there; of a mill, the taking of toll, &c.

These and such-like issues are termed esplees. In a writ of right of land, advowson, &c. the demandant must allege in his count, that he or his ancestors took the esplees of the thing demanded, otherwise the pleading is not good.

ESPOUSALS, in law, signifies a contract or promise made between a man and a woman, to marry each other; and in cases where marriage may be consummated, espousals go before. Marriage is termed an espousal *de præsenti*.

ESQUIRE, *armiger*, was anciently the person that attended a knight in time of war, and carried his shield.

This title has not, for a long time, had any relation to the office of the person, as to carry arms, &c. In England those to whom the title of esquire is now of right due, are all noblemen's younger sons, and the eldest sons of such younger sons; the eldest sons of knights, and their eldest sons; the officers of the king's courts, and of his household; councellors at law, justices of the peace, &c. when in the commission; but a sheriff of a county, who is a superior officer, retains the title of esquire during life, in consequence of the trust once reposed in him: the heads of some ancient families are said to be esquires by prescription; and by custom, or by way of compliment, this title is given to every gentleman who lives on his private fortune, and to rich merchants: it is even assumed by almost every tradesman who can drive his gig, or who takes upon him to live in two houses, though he should be unable to pay the expenses of one.

ESQUIRES *of the king*, are such as have that title by creation, wherein there is some formality used, as the putting about their necks a collar of SS, and bestowing on them a pair of silver spurs, &c.

There are four esquires of the body to attend the king's person.

If an esquire be arraigned for high treason, he ought to be tried by a jury each whereof have 40*s*. of freehold, and 100*l*. in goods; and a knight has no other privilege. The heir apparent of an esquire is privileged to keep greyhounds, setting-dogs, or nets to take partridges and pheasants, though he cannot dispend 10*l*. of estate of inheritance, or the value of 30*l*. of estate for life.

ESSENCE, in philosophy, that which constitutes the particular nature of each genus or kind, and distinguishes it from all others; being nothing but that abstract idea to which the name is affixed, so that every thing contained in it is essential to that particular kind.

ESSENDO QUIETUM DE TOLONIO, in law, a writ which lies for citizens, burgesses, &c. who by charter or prescription ought to be free from toll, in case the same is exacted of them.

ESSENES, or *essenians*, in Jewish antiquity, one of the three sects among that people, who exceeded the Pharisees in their most rigorous observances. They allowed a future state, but denied a resurrection from the dead. Their way of life was very singular: they did not marry, but adopted the children of others, whom they bred up in the institutions of their sect: they despised riches, and had all things in common; and never changed their cloaths till they were entirely worn out. When initiated, they were strictly bound not to communicate the mysteries of their sect to others; and if any of their members were found guilty of enormous crimes, they were expelled.

ESSOIN, in law, an excuse for a person summoned to appear and answer to an action, on account of sickness or other just cause of his absence.

It is a kind of imparlance or craving of longer time, and obtains in real, personal, and mixed actions.

There are divers essoins: as de ultra mare, when the defendant is beyond sea, whereby he is allowed forty days; in an expedition to the Holy Land, a year and a day; infirmity, called common essoin, when he is sick in bed; and lastly, in the king's service.

ESSOIN-DAY, is regularly the first day in every term, though the fourth day after is also allowed by way of indulgence.

ESSOIN DE MALO VILLÆ, is where the defendant appears in court, but before pleading, falls sick in a certain village: this is also allowed, if found true.

ESTATE, in law, signifies such inheritance, freehold, term for years, tenantcy by statute-merchant, staple, elegit, or the like, as any man has in lands and tenements. Estates are real, of lands, tenements, &c. or personal, of goods or chattels; otherwise distinguished into freeholds that descend to the heir, and chattels which go to the executors. Co. Lit. 315.

Of estate in fee-simple. An estate in fee-simple, is an estate, lands, tenements, lordships, advowsons, commons, estovers, and all hereditaments, to a man and his heirs for ever: also, where a corporation sole or aggregate are capable of holding in succession, and lands are given to them and their successors, they are said to have a fee-simple. 2 Bac. Abr. 249.

Of estate in tail. An estate is said to be intailed, when it is ascertained what issue shall inherit it.

What things may be intailed, by the statute of intails. The statute makes use of the word tenementum, and therefore the estate to be intailed, may be as well incorporated as corporeal inheritances, because the word tenementum comprehends the one as well as the other, and consequently, not only lands may be intailed, but all rents, commons, estovers, or other profits arising from lands. Co. Lit. 19, b. 20, a.

What words create an estate tail. When the notion of succession prevailed, it was necessary in feudal donations to use the word heirs, to distinguish such descendible feud from that which was granted only for life; but as to the word body, it was necessary to make use of that in the donation, but it might be expressed by any equivalent words, and therefore a gift to a man and hæredibus de se, or de carne quo sibi contigerit habere, or procreavit, is a good estate tail; for these sufficiently circumscribe the word heirs, to the descendants of the feudatory: and the reason of the difference is, because inheritances are only derived from the law, and the law requires the word heirs, that comprehends the whole notion of such legal representation; but the limiting the inheritance of the descendants of this or the other body, is only the particular intention of the person that forms the gift, and therefore the law leaves every man to express himself in such manner as may manifest that intention. 2 Bac. Abr. 259.

Of tenant in tail charging his estate. The statute de donis, affecting a perpetuity, restrained the donee in tail, either from alienating or charging his estate tail; and by that act the tenant in tail was likewise to leave the land to his heirs as he received it from the donor; and upon that statute the heir in tail might have avoided any alienation or incumbrance of his ancestors; and as the law stood upon that act, so might he in reversion, when the heirs of the donee failed, which were inheritable to the gift. The crown long struggled to break through the perpetuity which was established by this law; and in the reign of Ed. IV. we find the pretended recompence given against the vouchee in the common recovery to be allowed as equivalent for the estate tail; and because the recompence was to go in succession as the land in tail should have done, therefore they allowed the recovery to bar the reversion as well as the issue in tail, because he in the reversion was to have the recompence in failure of issue of the donee. 2 Bac. Abr. 265. See Recovery.

ESTOILEE', or *cross estoilee'*, in heraldry, a star with only four long rays in form of a cross; and, accordingly, broad in the centre, and terminating in sharp points.

ESTOPPEL, in law, an impediment or bar to an action, which arises from a person's own act; or rather, where he is forbidden by law to speak against his deed, which he may not do, even to plead the truth. Thus where a person is bound in a bond by such a name, and is afterwards sued by the same name on the obligation, he shall not be allowed to say he is misnamed, but shall answer according to the bond, though it be wrong. Hence the parties in all deeds are estopped from saying any thing against them. However, a plaintiff is not estopped from saying any thing against what he had said in his writ or declaration; and though parties may be estopped, yet juries are not so, who may find things out of the record.

ESTOVERS, in law, is a liberty of taking necessary wood for the use or furniture of a house or farm. And this any tenant may take from off the land let or demised to him, without waiting for any leave, assignment, or appointment of the lessor, unless he is restrained by special covenant to the contrary. 2 Black. 35.

ESTRAYS and waifs, in law. Estrays are where any horses, sheep, hogs, beasts, or swans, or any beast that is not wild, come into a lordship, and are not owned by any man. Kitch. 23. The reason of estray is, because when no person can make title to the thing the law gives it to the king, if the owner does not claim it within a year and a day.

Waifs are goods which are stolen, and waved or left by the felon, on his being pursued, for fear of being apprehended, and forfeited to the king or lord of the manor: and though waifs are generally spoken of things stolen, yet if a man is pursued with hue and cry as a felon, and he flies and leaves his own goods, these will be forfeited as goods stolen; but they are properly the fugitive's goods, and not forfeited till it is found before the coroner, or otherwise of record, that he fled for the felony. 2 Haw. 450.

Waifs and strays were anciently the property of the finders by the law of nature, and afterwards the property of the king by the law of nations. Dalt. Sher. 79. Waifs and strays not claimed within the year and day are the lord's. For where the lord has a beast a year and a day, and it has been cried in the church and markets, the property is changed. Kitch. 80. But it must be a year and a day from the time of proclamation, and not from the time of seizure; for it does not become an estray till after the first proclamation. 11 Mod. 89.

ESTREAT, is a true copy or note of some original writing on record, and especially of fines and amercements imposed in the rolls of a court, and extracted or drawn out thence, and certified into the court of exchequer: whereupon process is awarded to the sheriff to levy the same.

ESTREPEMENT, or Estrepament, the spoil made by a tenent for life, upon any lands or woods, to the prejudice of the reversioner.

Estrepement also signifies a writ which lies in two cases; the one is when the person having an action depending (as a formedon, or dum fuit infra ætatem, or writ of right, or any other), wherein the demandant is not to recover damages, sues to inhibit the tenant from making waste during the suit. The other is for the demandant that is adjudged to recover seisin of the land in question, and before execution sued by the writ habere facias seisinam, for fear of waste to be made before he can get possession: he then sues out of this writ.

ETCHING, is a manner of engraving on copper, in which the line or strokes, instead of being cut with a tool or graver, are corroded in with aquafortis.

It is a much later invention than the art of engraving by cutting the lines on the copper, and has many advantages over it for some purposes; though it cannot supercede the use of the graver entirely, as there are many things that cannot be etched so well as they can be graved.

In almost all the engravings on copper that are execu-

ted in the stroke manner, etching and graving are combined, the plate being generally begun by etching, and finished with the graver. Landscapes, architecture, and machinery, are the subjects that receive most assistance from the art of etching; for it is not so applicable to portraits and historical designs.

We shall first describe the various instruments and materials used in the art.

Copper-plates may be had ready prepared at the coppersmiths by those who reside in large towns; but when this cannot be had, procure a piece of pretty thick sheet-copper from a brazier, rather larger than your drawing, and let him planish it well; then take a piece of pumice-stone, and with water rub it all one way, till the surface is as smooth and level as it can be made by that means: a piece of charcoal is next used with water for polishing it still farther, and removing the deep scratches made by the pumice-stone; and it is then finished with a piece of charcoal of a finer grain, with a little oil.

Etching-points or needles are pointed instruments of steel, about an inch long, fixed in handles of hard wood, about six inches in length, and of the size of a goose-quill. They should be well tempered, and very accurately fixed in the centre of the handle. They must be brought to an accurately conical point, by rubbing upon an oil-stone, with which it is also very necessary to be provided. Several of these points will be necessary.

A parallel-ruler is necessary for drawing parallel straight lines. This is best when faced with brass, as it is not then so liable to be bruised by accident.

Compasses are useful for striking circles and measuring distances.

Aquafortis, or, what is better, spirit of nitre (nitrous acid), is used for corroding the copper, or biting in, as it is called. This must be kept in a bottle with a glass stopple, for its fumes destroy corks. A stopple made of wax will serve as a substitute, or a cork well covered with wax.

Bordering-wax, for surrounding the margin of the copper-plate when the aquafortis is pouring on. This may be bought ready prepared, but it may be made as follows:

Take one-third of bee's-wax to two-thirds of pitch; melt them in an iron ladle, and pour them, when melted, into water luke-warm; then mould it with your hand till it is thoroughly incorporated, and all the water squeezed out. Form it into rolls of convenient size.

Turpentine-varnish is used for covering the copper-plate with, in any part where you do not wish the aquafortis to bite. This may be diluted to a proper consistence with turpentine, and mixed with lamp-black that it may be seen better when laid upon the plate.

Etching-ground is used for covering the plate all over, previous to drawing the lines on it with the needles. It is prepared in the following manner:

Take of virgin-wax and asphaltum, each twenty ounces; of black-pitch and Burgundy-pitch, each half an ounce; melt the wax and pitch in a new earthenware glazed pipkin, and add to them, by degrees, the asphaltum, finely powdered. Let the whole boil till such time as by taking a drop upon a plate, it will break when it is cold, on bending it double two or three times between the fingers. The varnish being then enough boiled, must be taken off from the fire, and letting it cool a little, must be poured into warm water, that it may work the more easily with the hands, so as to form into balls for use.

It must be observed, first, that the fire be not too violent, for fear of burning the ingredients; a slight simmering will be sufficient. Secondly, that while the asphaltum is putting in, and even after it is mixed with them, the ingredients should be stirred continually with a spatola; and, thirdly, that the water into which this composition is thrown, should be nearly of the same degree of warmth with it, to prevent a kind of cracking, which happens when the water is too cold.

The varnish ought always to be harder in summer than winter, and it will become so if it is suffered to boil longer, or if a greater proportion of the asphaltum is used. The experiment above-mentioned, of the drop suffered to cool, will determine the degree of hardness or softness that may be suitable to the season when it is used.

To lay the ground for etching, proceed in the following manner. Having cleaned the copper-plate with some fine whiting and a linen rag, to free it from all grease, fix a hand-vice to some part of it where no work is intended to be, to serve as a handle for managing it by when warm. Roll up some coarse brown paper, and light one end; then hold the back of the plate over the burning paper, moving it about until every part of it is equally heated, so as to melt the etching-ground, which should be wrapped up in a bit of taffety, to prevent any dirt that may happen to be among it from mixing with what is melted upon the plate. If the plate is large, it will be best to heat it over a chafing-dish with some clear coals. It must be heated just sufficient to melt the ground, but not so much as to burn it. When a sufficient quantity of the etching-ground has been rubbed upon the plate, it must be dabbed, or beaten gently, while the plate is hot, with a small dabber made of cotton wrapped up in a piece of taffety, by which operation the ground is distributed more equally over the plate than it could be by any other means.

When the plate is thus uniformly and thinly covered with the varnish, it must be blackened by smoking it with a wax-taper. For this purpose twist together three or four pieces of wax-taper, to make a larger flame, and while the plate is still warm, hold it with the varnished side downwards, and move the smoky part of the lighted taper over its surface, till it is made almost quite black; taking care not to let the wick touch the varnish, and that the latter get no smear or stain. In laying the etching-ground, great care must be taken that no particles of dust or dirt of any kind settle upon it, as that would be found very troublesome in etching: the room therefore in which it is laid should be as still as possible, and free from dust.

The ground being now laid, and suffered to cool, the next operation is to transfer the design to the plate.

For this purpose a tracing on oiled paper must now be made, from the design to be etched, with pen and ink, having a very small quantity of ox's gall mixed with it, to make the oiled paper take it; also a piece of thin paper, of the same size, must be rubbed over with red chalk, powdered, by means of some cotton. Then laying the red-chalked paper, with its chalked side next

the ground, on the plate, put the tracing over it, and fasten them both together, and to the plate, by a little bit of the bordering-wax.

When all this is prepared, take a blunt etching-needle, and go gently all over the lines in the tracing; by which means the chalked paper will be pressed against the ground, and the lines of the tracing will be transferred to the ground: on taking off the papers they will be seen distinctly.

The plate is now prepared for drawing through the lines which have been marked upon the ground. For this the etching-points or needles are employed, leaning hard or lightly, according to the degree of strength required in the lines. Points of different sizes and forms are also used for making lines of different thickness, though commonly this is effected by the biting in with the aquafortis.

A margin or border of wax must now be formed all round the plate, to hold the aquafortis when it is poured on. To do this, the bordering-wax already described must be put into lukewarm water to soften it, and render it easily worked by the hand. When sufficiently pliable it must be drawn out into long rolls, and put round the edges of the plate, pressing it down firm, and forming it with the fingers into a neat wall or margin. A spout must be formed in one corner, to pour off the aquafortis afterwards.

The nitrous acid (spirit of nitre) is now to be diluted with four or five times as much water, or more (according as you wish the plate to be bitten quick or slow), and poured upon the plate. In a few minutes you will see minute bubbles of air filling all the lines that have been drawn on the copper, which are to be removed by a feather; and the plate must be now and then swept, as it is called, or kept free from air-bubbles. By the more or less rapid production of these bubbles, you judge of the rapidity with which the acids acts upon the copper. The biting in of the plate is the most uncertain part of the process, and nothing but very great experience can enable any one to tell when the plate is bitten enough, as you cannot easily see the thickness and depth of the line till the ground is taken off.

When you judge from the time the acid has been on, and the rapidity of the biting, that those lines which you wish to be the faintest are as deep as you wish, you pour off the aquafortis by the spout, wash the plate with water, and dry it, by blowing with bellows, or by the fire, taking care not to melt the ground.

Those lines that are not intended to be bitten any deeper, must now be stopped up with turpentine-varnish mixed with a little lamp-black, and laid on with a camel's hair pencil; and when this is thoroughly dry the aquafortis may be poured on again, to bite the other lines that are required to be deeper.

This process of stopping out and biting in is to be repeated as often as there are to be lines of different degrees of thickness, taking care not to make any mistake in stopping out wrong lines.

It is also necessary to be particularly careful to stop out with the varnish those parts from which the ground may happen to have come off by the action of the acid, otherwise you will have parts bitten that were not intended, which is called foul-biting.

When the biting in is quite finished, the next operation is to remove the bordering-wax and the ground, in order that you may see what success you have had; for till then this cannot be known exactly.

To take off the bordering-wax the plate must be heated by a piece of lighted paper, which softens the wax in contact with the plate, and occasions it to come off quite clean.

Oil of turpentine is now poured upon the ground, and the plate is rubbed with a bit of linen rag, which removes all the ground. Lastly, it is cleaned off with whiting.

The success of the etching may now be known, but it is necessary to get an impression taken upon paper by a copper-plate printer. This impression is called a proof.

If any parts are not bitten so deep as were intended, the process may be repeated; provided the lines are not too faintly bitten to admit of it. This second biting-in in the same lines is called re-biting, and is done as follows: Melt a little of the etching-ground on a spare piece of copper, and dab it a little, to get some on the dabber; then having cleaned out with whiting the lines that are to be rebitten, heat the plate gently, and dab it very lightly with the dabber. By this the parts between the lines will be covered with the ground; but the lines themselves will not be filled up, and consequently will be exposed to the action of acquafortis. This is a very delicate process, and must be performed with great care. The rest of the plate must now be varnished over, the bordering-wax put on again, and the biting repeated in the same manner as at first.

If any part should be bitten to deep, it is more difficult to recover it, or make it fainter: this is generally done by burnishing the part down, or rubbing it with a piece of charcoal. This will make the lines shallower, and cause them not to print so black.

Should any small parts of the lines have missed altogether in the biting, they may be cut with the graver; which is also sometimes employed to cross the lines of the etching, and thus to work up a more finished effect.

Dry-pointing, as it is called, is another method employed for softening the harsh effects usually apparent in an etching. This is done by cutting with the etching-point upon the copper without any ground or varnish. This does not make a very deep line, and is used for covering the light, where very delicate tints and soft shadows are wanting. By varying these processes of etching, graving, and dry-pointing, as is thought necessary, the plate is worked up to the full effect intended; and it is then sent to the writing-engraver, to grave whatever letters may be required to be put upon it.

Etching on glass.—Glass resists the action of all the acids, except the fluoric acid. By this, however, it is corroded in the same manner as copper is by aquafortis; and plates of glass may be engraven in the same manner as copper.

There are several methods of performing this. We shall first describe the mode of etching by means of the fluoric acid in the state of gas. Having covered over the glass to be etched with a thin coat of virgin-wax (which is only common bee's-wax bleached white), draw

the design upon it in the same manner as in etching on copper. Then take some fluor spar, commonly called Derbyshire spar, pound it fine, and put it into a leaden vessel, pouring some sulphuric acid over it. Place the glass with the etched side lowermost over this vessel, two or three inches above it. Apply a gentle heat to the leaden vessel; this will cause the acid to act upon the fluor spar, and disengage the gas, which will corrode the glass. When it is sufficiently corroded, remove the wax by oil of turpentine.

This etching may be also performed by raising a margin of bordering-wax all round the glass, in the same manner as on copper, and pouring on the liquid fluoric acid, which acts upon the glass. The method of making this acid is described under FLUORIC ACID, and in the article CHEMISTRY.

A third method of etching on glass is as follows: Having put the wax on the glass, draw your design, and raise a margin all round it. Then put pounded fluor spar, with some sulphuric acid diluted with water, upon the glass. The sulphuric acid will disengage the fluoric, which will be absorbed by the water, and corrode the glass.

ETHICS, or MORALITY, the science of manners or duty, which it traces from man's nature and condition, and shows to terminate in his happiness; or, in other words, it is the knowledge of our duty and felicity, or the art of being virtuous and happy.

Moral philosophy inquires, not how man might have been, but how he is constituted; not into what principles or dispositions his actions may be artfully resolved, but from what principles and dispositions they actually rose; not what he may, by education, habit, or foreign influence, come to be or do, but what by his nature or original frame, he is framed to be and do. From a view, therefore, of man's faculties, appetites, and passions, it appears, that the health and perfection of man must be in the supremacy of conscience and reason, and in the subordination of the passions and affections to their authority and direction; and his virtue or goodness must consist in acting agreeably to this order and economy.

It is true, some eminent philosophers have attempted to lay the foundation of morals much deeper, viz. in the nature and reason, the truth and fitness of things. Senses and affections, they tell us, are vague and precarious; and though they were not, yet are irrational principles of action, and consequently very improper foundations, on which to rest the eternal and immutable obligations of morality. Hence they talk much of the abstract nature and reason of things, of eternal differences, unalterable relations, fitnesses and unfitnesses resulting from those relations; and from these eternal reasons, differences, relations, and their consequent fitnesses, they suppose moral obligation to arise. A conduct agreeable to them, or, in other words, to truth, they call virtue; and the reverse, vice. But the truth is, that we might perceive all the possible relations, differences, and reasons of things, and yet be wholly indifferent to this or that conduct, unless we were endued with some sense or affection by which we approved and loved the one, and disapproved and disliked the other conduct. Reason may perceive a fitness to a certain end; but without some sense or affection we cannot propose or indeed have any idea of an end or motive; and without an end, we cannot conceive any inducement to action. Therefore, before we can understand the natures, reasons, and fitnesses of things, which are said to be the foundation of morals, we must know what natures are meant, to what ends they are fitted, and from what principles or affections they are prompted to act; otherwise we cannot judge of the duty required, or of the conduct becoming that being whom we suppose under moral obligation. But let the natures be once given, and the relations which subsits among them be ascertained, we can then determine what conduct will be obligatory to such natures, and adapted to their condition and economy. And to the same natures, placed in the same relations, the same conduct will be eternally and invariably proper and obligatory.

Besides to call morality a conformity to truth, gives no idea, no characteristic of it, but what seems equally applicable to vice. For whatever propositions are predicable of virtue (as, that it flows from good affections, or is agreeable to the order of our nature, tends to produce happiness, is beheld with approbation, &c.); the contrary propositions are equally true, and may be equally predicated, of vice.

Another set of philosophers establish morals upon a better foundation, the will or positive appointment of the Deity, and call virtue a conformity to that will or appointment. All obligation, they say, supposes one who obliges, or who has a right to prescribe, and can reward the obedient, and punish the disobedient. This can be none but the Creator. His will, therefore, is our law, which we are bound to obey. And this, they tell us, is alone sufficient to bind or oblige such imperfect and corrupt creatures as we are, who are but feebly moved with a sense of the beauty and excellence of virtue, and strongly swayed by passion or views of interest.

This scheme of morality entirely coincides with that deduced from our inward structure and condition, since these are the effects of the divine will. Whatever, therefore, is agreeable or correspondent to our inward structure, must likewise be agreeable, or correspondent to the will of God. So that all the indications or sanctions of our duty, which are declared or enforced by our structure are, and may be, considered as indications or sanctions of the will of our Creator. If these indications, through inattention to, or abuse of, our structure, prove insufficient to declare: or if these sanctions, through the weakness or wickedness of men, prove insufficient to enforce obedience to the divine will, and the Deity is pleased to add new indications or new sanctions; these additional indications and sanctions cannot, and are not supposed by the assertors of this scheme, to add any new duty or new moral obligation; but only a new and purer promulgation of our duty, or a new and stronger sanction or motive from interest to perform that duty, and to fulfil that obligation to which we were bound before. It makes no difference as to the matter of obligation, after what manner the will of our Creator is enforced or declared to us, whether by word or writ, or by certain inward notices and determinations of our own minds, arising according to a necessary law of our nature. Again, if the scheme of duty, as deduced from moral perceptions, and the affections of our nature, is

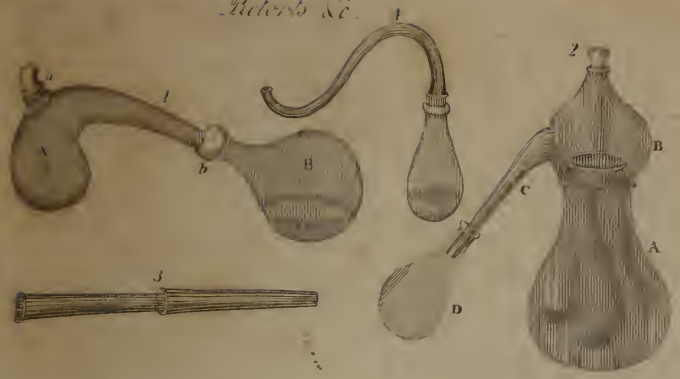
thought too slight a foundation on which to rest morality, because these are found insufficient to bind or rather to compel men to their duty, we fear the same objection will militate against the scheme of conformity to the divine will, since all the declarations and sanctions of it have not hitherto had their due effect, in producing a thorough and universal reformation.

When some speak of the will of God as the rule of duty, they do not certainly mean a blind, arbitrary principle of action, but such a principle as is directed by reason and governed by wisdom, or a regard to certain ends in preference to others: for unless we suppose some principle in the Deity analogous to our sense of obligation, some antecedent affection or determination of his nature to prefer some ends before others, we cannot assign any sufficient reason why he should will one thing more than another. Whatever, therefore, is the ground of his choice or will, must be the ground of obligation, and not the choice or will itself. That this it the case, appears farther from the common distinction which divines and philosophers make between moral and positive commands and duties. The former they think obligatory antecedent to will, or at least to any declaration of it; the latter, obligatory only in consequence of a positive appointment of the divine will. But what foundation can there be for this distinction, if all duty and obligation is equally the result of mere will?

Whatever may have been the reasoning of heathen philosophers on this subject (and to which, indeed, this article chiefly refers), the professors of christianity have no difficulty in understanding what is the will of God; and consequently what are the true principles of moral duty. That these were not understood by the wisest of the heathens, is evident from their practice, and still more so from even their speculative, their cool, deliberate, and well digested reasonings. (See Gregory's Essays Historical and Moral; Essay on the Pprinciples of Morals.) But christians are furnished not only with the strongest motives but with the most clear and decisive precepts for the performance of their duty. The excellence of the gospel in this respect supercedes the necessity of all human speculations; and hence nothing can be more idle or fruitless than to search for moral instructions in the writings of the heathens. Nor can any thing be more a work of supererogation to men who have the Bible in their hands, than systems of ethics, or lectures on moral philosophy! On this account we have made this article very short, and given rather the opinions of others than our own, merely to show (as matter of information) what has been said and thought upon the subject.

Before we conclude this article, it will be proper to say something of the extraordinary hypothesis of Hobbess, concerning the foundation of morality. This philosopher, who saw his country involved in all the distraction and misery of a civil war, seems to have taken too narrow and partial a view of our nature, and has therefore drawn it in a very odious and uncomfortable light. Next to the desire of self-preservation, he makes the love of glory and of power to be the governing passions in man; and from these, by an arbitrary, unnatural, and unsupported hypothesis, contrary to common experience and common language, he attempts to deduce all the other passions which inflame the minds and influence the manners of men. According to him all men are equal, all desire and have a right to the same things, and want to excel each other in power and honour; but as it is impossible for all to possess the same things, or to obtain a pre-eminence in power and honour, hence must arise a state of war and mutual carnage; which is what he calls a state of nature. But this shrewd philosopher subjoins, that men being aware that such a state must terminate in their own destruction, agreed to surrender their private unlimited right into the hands of the majority, or such as the majority should appoint, and to subject themselves for the future to common laws or to common judges or magistrates. In consequence of this surrender, and of this mutual compact or agreement, they are secured against mutual hostilities, and bound or obliged to a peaceable behaviour; so that it is no longer lawful or just (he certainly means safe or prudent) to invade and incroach on one another, since this would be a violation of his promise. But one may ask him, what obligation is a man under to keep his promise or stand to his compact, if there is no obligation, no moral tie, distinct from that promise? On the whole, his state of nature is a mere chimera, and the superstructure he has raised on it no less so.

ETHER. See ÆTHER.



ETHMOIDAL, in anatomy, one of the common sutures of the skull, which goes round the os ethmoids, from which it derives its name, separating it from the bone in contact with it.

ETHNOPHRONES, in church history, a sect of Christians of the seventh century, who, professing christianity, joined to it all the ceremonies and follies of Paganism, such as judicial astrology, divinations of all kinds, &c. and who observed all the feasts, times, and seasons, of the Gentiles.

ETHOPOEIA, or ETHOLOGY, in rhetoric, a draught or description, expressing the manners, passions, genius, tempers, aims, &c. of any person. Such is that noted picture of Cataline, as drawn by Sallust: *fuit magna vi et animi*, &c. "He was a man of great vigour both of body and mind; but of a disposition extremely profligate and depraved. From his youth he took pleasure in civil wars, massacres, depredations, and intestine broils: and in these he employed his younger days. His body was formed for enduring cold, hunger, and want of rest, to a degree indeed incredible: his spirit was daring, subtle, and changeable; he was expert in all the arts of simulation and dissimulation, covetous of what belonged to others, lavish of his own, violent in his passions: he had eloquence enough, but a small share of wisdom; his boundless soul was constantly engaged in extravagant and romantic projects, too high to be attempted."
